Now, passing to the last article on the Home Farm, farmers are really not such ignoramus as the writer implies. There are new departures on every hand. Perhaps your correspondent forgets that in farm agreements there may be certain stringent clauses which bind men down to the ways of their ancestors; but apart from this, money, time, and energy are expended with judgment by competent men; nothing is overlooked from the largest to the smallest item. What of the "middleman?" Yes, he is a product of the times, an evil, but at present a necessary one. In old days fairs were held near home twice or at most four times a year; buyer and seller were well known to each other. Now fairs are things of the past, the weekly and fortnightly market taking their place. Is it possible that a farmer with stock to sell three or four times a year could do so well as a man who never misses a market year in year out, a man specially adapted for the business? If Government would take up the railway system of this country, and so lower the rates for small quantities, much farm and garden produce would pass direct from producer to consumer, and so benefit both.

Just a few instances of farm enterprise, not taken from any farming journal, but just selected as being cases near home. One man takes up milk, also Celery and Potato growing, always buying the best in the market, and not hesitating as to price. Another by special attention turns out such sheep as cannot be matched between the four seas. Another raises and puts on to the market one of the best Barleys of this decade. Another clears his rent by his hunters (do not try to emulate him, dear amateur). Another by hackney breeding has rehabilitated the fallen fortunes

of his family. Four wheels will not carry the wagon of another, so he adds a fifth in the shape of a willow garth. Strawberries figure largely in the balance-sheet of another. Acres (600) of bad weak land are bought, washed by the rich waters of the Trent, the produce sent to and manure brought from the Cottonopolis, the carriage of which has been raised since January 1st £700 per annum. Now it is a question as to whether that farm should not go out of cultivation. These new railway rates fairly kill all enterprise, and a change is imperative.

Well, now, *re* feeding stuffs. Animals here do not like and will not have ensilage. Wheat and Barley may be good feeding stuffs, but it is very easy to over-use them, and their manurial value is not great (all land will not grow Oats, or that other valuable food, Beans). No one nowadays buys cake without analysis, and that analysis guarantees a good per-centage of oil. Has your friend had much experience in carting green stuff and cutting up the same to convert it into ensilage? The carting alone costs more than the whole process of hay making, and a very inferior article is produced.

I know all pasture land is not drained; draining costs money, and a great deal too; and what about that land (Holderness) that must be re-drained at least every eight years? Unless the landlord does it, the farmer must have a long purse and a large heart to face such a difficulty. In the parish in which I reside elementary classes for agricultural chemistry are being held; very good, too, but not quite elementary enough. Science without practice leads to starvation. "Twitch out, tillage in," must be learnt first, then the rest may follow.

Passing to Potatoes, there is an advertisement in your front page which interests me. A few days ago a friend gave me twelve "Jeannie Deans" as a great favour; some were steamed, some roasted, all were simply splendid. I think I shall send for a few pecks. I hope I have hurt no one's feelings by this little critique. I do not want to do so, but there are two sides to a question always, even if the other is but that of—A FARMER'S WIFE.

[We like a change of fare, as do our readers, and we insert the able critique with the utmost readiness; and as a lady "born and bred," as well as a real farmer's wife, we concede our correspondent the privilege of presenting one or two of her strong points in italics, and telling points they are, as will be admitted. We happen to know that the farmer himself, whose life our correspondent does so much to make happy, and whose alertness of intellect must often have been helpful to him, is one of the most diligent, competent, and successful of the important class to which he belongs, and we have no hesitation whatever in saying that if all farmers were like him in knowledge of his business, means acquired in it, and prudential habits of life, numbers of estates, and in the aggregate hundreds of thousands of acres of land, would not be in the sad plight they are to-day.]

We do not think this excellent farmer has wasted much money in the hunting field, and we suspect if he indulged in that sport he would make it pay; but he is somewhat of a sportsman all the same, and enjoys himself, as he has full right to do, in the form of recreation which he finds pleasurable and health-giving; but business first, we have not a doubt, has been and is his motto, and that is why he is what he is—a prosperous man, *though* a farmer. Nor is his garden neglected; and if all the great gardens were as well kept as his is they would be more creditable to the proprietors and beneficial to the dependants on the estates. We are glad to know that in this particular farmer's case that the "old and new styles" indicated in the ancient doggerel on page 192 are happily blended, and we are conscious that both he and his accomplished help-meet will take very good care not to be "gazetted," as will our home farmer and estate critic, who can look after themselves and live by their good work on the land. We thank our fair correspondent for her interesting communication.]

## PRACTICAL AND SCIENTIFIC TEACHING.

THE depression that has long existed, and is still very acute, in our chief industry—agriculture—prompts me to offer some suggestions respecting the cultivation of fruit. Absolute experience or agricultural chemistry can alone decide what class of fruit is the best suited for the soil and climate existing in respect of the quantity and quality produced. Some rules, however, seem to be pre-eminent. Keep all fruit grounds free and open on the surface, and free from weeds, and never attempt to grow ground or bush fruit under orchard trees, or ground fruit and bush fruit together. Each class must be separate and distinct.—ENGLISHMAN.

[The above is only a small portion of a long letter, in which the writer at the outset conveys the idea that he desires to develop fruit culture in England, yet goes on to suggest, though he does not say so, that Englishmen may invest with advantage their savings elsewhere than at home in the production of fruit. No doubt it is true that some persons may do so, but as a rule those who fail at home are not the most likely to succeed abroad; and we also suspect that at least some of the tempting invitations held out to small capitalists to invest in fruit culture in various parts of the world are not altogether dissociated from shipping agents and land sellers, and we advise the exercise of extreme caution and searching inquiry by persons before investing their savings in enterprises in distant lands, "boomed" as so many are by capitalists or adventurers.

We do not wish to imply that our correspondent, who is a J.P., is animated by other than the purest motives in what he sends us, and which we do not publish, but we are bound to say he appears to us to be lacking in the "absolute experience" that is requisite for either successful working or sound teaching in fruit culture.

As an alternative to actual experience he specifies "agricultural chemistry" alone as a safe guide to the cultivator. We are not likely to underrate the importance of scientific knowledge, but the acquisition of this, and nothing else, may render a scientist a very *unsafe* guide in practical work of supreme moment to persons who may be induced to invest their savings in it. We are cognisant of deductions being drawn from scientific facts and cultural methods advocated by savants without practice, which if adopted would end in disaster. Skill in the laboratory does not nor cannot suffice for teaching either the cultivation of fruit or anything else, and those students who rely on it solely will find themselves ill equipped for competition with men who have been trained in the utilitarian school of experience.

Our correspondent, whose type-written letter we may presume will go the "rounds of the press" and possibly find insertion in some journal or newspaper, reveals his lack of practical knowledge in the last sentence we print from his letter. "Each class of fruit must be grown separate and distinct." There must then be no Gooseberry or Currant bushes in the vacant spaces between rows of Apples or Plums. It is a fact that the most profitable plantations to be found are arranged on the system that is so emphatically condemned, and this method of occupying the ground is extending and will extend. That the separate system will and does answer under good management goes without saying, but that available space between rows of the larger fruits may not be utilised with the smaller and earlier bearing is a proposition that will somewhat amuse those skilled growers who pursue the method extensively and successfully.

There appears to be something in fruit culture that impels almost all sorts and conditions of men to become teachers of the art. They read books and newspaper articles, and think that in the course of an hour or two they have obtained a grip of the whole question and are forthwith qualified to pose as authorities, and they forthwith lead or mislead the public by their plausible expatiations. A case in point comes to hand. In a scholastic establishment, in which fruit culture is to be taught, a meeting has been held and a lecture given on the life history of the scale insect, and spraying with either Paris green or London purple was recommended by the "professor" as a remedy. It was then decided to spray one of the plantations with Paris green and another with London purple to destroy the insects. This is an instance of the worse than uselessness of scientific teaching alone and apart from the teaching of experience, because time, material, and labour will be wasted, the scale in the meantime increasing. The so-called remedies mentioned are useless against scale and also against the Currant bud mite they are vainly supposed to destroy.

Teaching founded on successful experience alone is vastly more useful than that based on science alone, though we shall perhaps shock the tender susceptibilities of the scientists by the assertion. It is true all the same; but science and practice should, as far as possible, go hand in hand; and it would be better for their

representatives to try and help each other than to indulge in the somewhat vain-glorious habit of a parade of superiority on either side, and thus reveal weakness rather than strength.]

## EARL'S COURT EXHIBITION, 1893.

A REPRESENTATIVE meeting of horticulturists was held recently at the Hotel Windsor, Mr. H. E. Milner being in the chair. Among those present were Messrs. William Paul, T. Francis Rivers, J. Cheal, H. G. Cutbush, John Laing, Harry Turner, and several others. The Chairman, after having thanked those present for their kindness in coming, gave a brief programme for the Exhibition of Gardening and Forestry to be held at Earl's Court this year, which, especially as regards the Forestry Section, at present the most advanced, is being cordially supported by the Woods and Forest Department and the Agents-General for the Colonies, also the leading landed proprietors. Mr. Milner stated that the Exhibition was promoted by private enterprise; at the same time he saw no reason why practical and scientific horticulture and forestry should not be advanced by this year's Exhibition. It was mainly with this object in view that he was induced to take the prominent position he has, and he hoped that those present, and all horticulturists, would give him their support, not only in their own interests, but also for the benefit of the general public. Mr. George Cadell had undertaken the charge of the Forestry Department, and in his capable hands he was sure that that section would be well represented.

With regard to horticulture, it is proposed to hold a series of flower shows fortnightly, commencing on May the 13th until the end of September, under canvas this year, and efforts will be made to make the display, as far as possible, continuous in the intervals between the fortnightly shows.

In the grounds it is proposed to demonstrate the planting of woods for cover and shelter suitable for the four main classes of soil, specimen of timber and ornamental trees, especially those usually classed as pictorial trees.

It is also proposed that this section, which will doubtless prove of great interest to landed proprietors and managers of forests, be further supplemented by a series of representations of the best evergreen, deciduous trees, and shrubs suitable for London and town gardens, and other features likely to be of value from an educational point of view. Very liberal prizes will be offered in the competitive classes at the fortnightly shows, and, with regard to extraneous exhibits, it is proposed that the awards shall take the form of silver cups or silver plate, instead of medals; but a gold medal of higher value will be awarded to exhibits of superlative merit.

The proposals set forth by Mr. Milner were heartily supported by Mr. William Paul, who remarked that in consideration of the able and satisfactory manner in which the International Horticultural Exhibition of last year was conducted by Mr. Milner, he thought that he and his confrères could have complete confidence in his programme for this year, and should exert themselves to carry out the proposals set before them. Mr. Rivers, Mr. Laing, and others were also of the same opinion, and promised their best support. A small committee was then formed to draw up the schedule and carry out the details.

H.M. Commissioner of Woods and Forests, the Trustees of the British Museum, the Director of the Science Division, and the Keeper of Zoology, South Kensington; the Deputy Surveyors of the New Forest and Dean Forest, &c., have already promised their valuable aid and exhibits; while under the kind permission of the Science and Art Department, a collection of woods from Japan, a country which possesses the most remarkable variety of flora in the world, will be shown. Although this will hardly permit a display of what may be called international Gardening and Forestry, the Exhibition bids fair to be more truly international in its character than others which have with less show of reason assumed the title. It will, in any case, unite in friendly rivalry competitors from other countries besides our own little island.

## SILVER MEDAL ESSAY.

### MANURES AND THEIR USES.

By Mr. G. A. BISHOP, *The Gardens, Wightwick Manor, Wolverhampton.*

(Concluded from page 175.)

PASSING from manures for fruit crops we now come to vegetables and plants. Vegetables are grouped in sections—root crops, green crops, and leguminous crops, but the space at disposal does not enable them to be treated fully.

## ROOT CROPS.

Potatoes, Parsnips, Carrots, Jerusalem Artichokes, Turnips, and Onions come under the above heading.

*Potatoes*.—Sandy loam is the best natural soil for Potatoes. Should the land be stiff means should be adopted to improve it. All the old mortar that can be had should be used, and if sand is near labour could not be more profitably employed than in carting it upon the heavy land. Wood ashes and burnt refuse generally are excellent for this important crop.

I will describe an experiment of my own. We had a very large heap of rubbish, which was burnt with plenty of wood; about thirty loads of this were put upon an acre, and about 15 tons of farmyard manure. Half a hundredweight of sulphate of iron was also spread on, and all ploughed in together. The Potatoes were planted after the plough, and the next round was turned upon the planted Potatoes, the whole of the manure falling upon them. The crops of all the varieties—early, medium, and late—were good, Chiswick Favourite exceptionally so. The tubers were of exhibition quality, excepting about one bag per acre. The yield was three to four bags (of 180 lbs.) per rood, and the Potatoes are fetching 1s. 6d. per bag above other people's, because of quality. Grown without any manure, the yield was from one to one and a half bags (of 180 lbs.) per rood, including many diseased tubers. I should add that 3 cwt. of superphosphates and 3 cwt. of kainit were given before the plants were ridged up.

*Parsnips* in deeply prepared and well pulverised ground always do well with a dressing of the chemicals just named, and basic slag as containing lime is excellent for this crop.

*Carrots* are often very difficult to obtain good. I grew about an acre this year, the finest I have seen, and the credit for this I give to kainit. I had the ground ploughed and ridged, then sown with 3 cwt. of kainit per acre. The ridges were split and the seed drilled above the kainit. The crop was heavy and the roots fine without any being injured with wireworm, yet in a patch close by not dressed with kainit, the roots were spoilt by that pest.

*Turnips*.—These will do in any fertile garden soil if plenty of lime is used, top-dressing with nitrate of soda; the nitrogen will improve the Turnips if too much farmyard manure has not been given. Superphosphate will supply the lime; it may be used mixed, say, in the proportion of 3 lbs. of superphosphate to 1 lb. of nitrate of soda, and given at the rate of 8 lbs. per rod.

*Onions*.—Soil made rich with farmyard manure should form the basis for this crop, adding all the wood ashes and burnt soil obtainable. Good drenchings with strong cesspool liquid once or twice during growing period will materially increase the value of the yield.

## GREEN CROPS.

Brussels Sprouts, Cabbage, Cauliflowers, Broccoli, Kales and all classes of the Brassicas, come under this heading. If the soil is treated as mentioned in the trenching for fruit trees, little else is required, but a slight dressing of about 1 to 1½ lb. of nitrate of soda and twice that quantity of kainit per rod will improve the heads and hearts without causing grossness. The per-centage of common salt, potash and soda is high in this family; and additions of kainit and nitrate of soda will supply these essentials. Phosphoric slag is also applied at the rate of 4 lbs. per rod.

## LEGUMINOUS CROPS.

Peas and Beans comprise all the important leguminous plants that concern the gardener. Very little nitrogenous manure need be given to this family, as it is considered that they can appropriate the free nitrogen. I prefer growing them in trenches containing a 6-inch dressing of good cow manure. Kainit and superphosphate, at the rate of 6 lbs. per rod, may be applied with advantage in rainy weather.

## MANURES FOR PLANTS GROWN UNDER GLASS.

This is a most comprehensive subject, and is in itself enough for a whole essay; it will be impossible to do it justice in the small space that I have at my disposal. I will treat upon the soil first, and then divide the plants into groups for the application of manure.

Loam is the most important material for potting. This should be obtained from a pasture several years old, where the fibrous roots are 6 or 8 inches deep. In that case it can be dug and carted into stacks that should be weather-proof; manure from fat stock being spread between the layers of soil, and to every third layer a good dressing say 4 lbs. of kainit to each 4 square yards. The heap should be allowed to stand several months before using, and the soil will then be in first-class condition.

Leaf soil should be stored in heaps, and a little soot or a small quantity of lime may be added to clear it of worms, snails, and insects. Cow or sheep manure rubbed through sieves may be added to the compost before use; but care should be exercised to have the manure heated first to destroy the eggs of insects. Old Mushroom bed refuse affords a good addition for quick-growing plants. Artificial manures ought not to be added to potting compost, as they are much better given when the plants are established.

Cinerarias, Calceolarias, Pelargoniums, Primulas, Fuchsias, and all similar plants, when established, can be watered with solutions made in the following proportions, to be applied at short intervals in the growing period:—Nitrate of soda, 1 lb. to 20 gallons rain water; superphosphate, 2 lbs. to the same quantity of water; sheep manure, 1 peck to 25 gallons, or guano, 1 lb. to 25 gallons of water. Cow manure and soot placed in bags in tubs, 4 gallons to 20 gallons of water. Only one of the above to be used at a time.

As top-dressings, Thomson's, Clay's, Beeson's, or Standen's fertilisers may be used at the rate of a teaspoonful to a 6-inch pot, blood manure at half, and guano at a quarter the above strength.

Crotons, Tabernæmontanas, Gardenias, Dracænas, Ixoras, Bougainvilleas, Stephanotis, Clerodendron, and similar plants should be encouraged by frequent application of liquid and top-dressings of manure. The period of application of manure will begin in March for all the above, and last till August, after which time less dressing and weaker ones must be given; do not drop off altogether or the plants will suffer in winter. I cannot do better than recommend the manures above mentioned, which are those I use myself with excellent results.

## LIQUID MANURE.

The urine and drainings from stables, cow-sheds, and other places should be carefully collected. It is a good plan to have a cistern or tank underground, into which the whole of these drainings can run. These are especially valuable as containing about 80 per cent. of the whole of the nitrogen produced in the excretions.

In making liquid from artificial manure, it must be noted that, as a rule, only soda, potash, and ammonium salts and calcium superphosphates will dissolve, and that a residue will remain which will be valuable, so that the turbid liquid should be well stirred before application, or, if allowed to stand, the residue should be used as a top-dressing. These remarks especially apply to some of the mixtures I have recommended.

## CONCLUDING REMARKS.

Farmyard manure is invaluable on clayey loams, because it contains a little of all the ingredients required by plants. This soil does not require so much manure as do light sandy soils, not only because of what is naturally contained in them, but on account of heavy soils retaining the matter added. Owing to the slow decomposition of farmyard manure nitrogen may not be liberated fast enough to allow of the plant to appropriate the potash and phosphates at its disposal; in that case Peas, Beans, Carrots, and Potatoes will be stringy or hard, and it will be necessary for an application of a nitrogenous manure, such as nitrate of soda or nitrogenous guano; chemical manure containing 100 lbs. of nitrogen will supply this element at once for assimilation by plants, yet that quantity in farmyard manure might not be liberated in six months because of its slow decomposition. Dressing with lime will liberate nitrogen both from farmyard manure and from organic matter in the soil.

Sandy soils are deficient in manurial qualities, and great care should be exercised in selecting manures, so that the least waste is occasioned. Good well-decayed manure from fat cattle is the best possible manure for sandy soils; clay added, and allowed to be exposed to the frost for disintegration, will assist in retaining moisture; and the farmyard manure will supply phosphates, alkalies, and silicates in a soluble form. For the assistance of crops which require potash and phosphates, kainit and superphosphate must be added at the rate of 3 to 4 cwt. of each per acre. Light sandy soils are deficient in nitrogen, owing to its being so quickly washed away into drains and subsoils, therefore it must be supplied by surface dressing with nitrate of soda or sulphate of ammonia during the growing period of the crop, at the rate of ½ to 1 cwt. per acre. One or two dressings may be given to these soils. Phosphates, and if necessary kainit, should be used at the same time with the nitrogenous manures.

In the few remarks I have yet to make may I again call the attention of readers to the composition of the various manures given in the first part of this essay, where they will see their constituents? The following gives the dominating constituents of the various garden crops

as correctly set forth in Messrs. Sutton & Sons' useful work, the "Cultivation of Vegetables and Flowers."

"Vegetables in which *phosphates and potash predominate*:—The ash of these will contain the following constituents in the proportions stated below. The Pea.—Phosphates, 36 per cent.; potash, 40 per cent. The Bean.—Phosphates, 30 per cent.; potash, 44 per cent. The Potato (tubers only).—Phosphates, 19 per cent.; potash, 59 per cent.; soda, 2 per cent.; lime, 2 per cent.; sulphuric acid, 6 per cent. The Parsnip.—Phosphates, 18 per cent.; potash, 36 per cent.; lime, 11 per cent.; salt, 5 per cent. The Carrot.—Phosphates, 12 per cent.; potash, 36 per cent.; soda, 13 per cent.; sulphuric acid, 6 per cent. The Artichokes.—Phosphates, 16 per cent.; potash, 65 per cent. Vegetables in which *sulphur, soda, and salt predominate*.—The Cabbage.—Phosphates, 16 per cent.; potash, 48 per cent.; soda, 4 per cent.; lime, 15 per cent.; sulphuric acid, 8 per cent. The Turnip.—Phosphates, 13 per cent.; potash, 39 per cent.; salt, 10 per cent.; lime, 10 per cent.; sulphuric acid, 14 per cent. The Beet.—Phosphates, 14 per cent.; potash, 49 per cent.; soda, 9 per cent.; salt, 20 per cent.; lime, 6 per cent.; sulphuric acid, 5 per cent."

If the constituents of crops were taken as a basis for manuring in connection with the physical character of the soil and the food ingredients it naturally contains, better results would accrue than from haphazard methods, and the cultivator would have a reward for his intelligence and skill.

#### N.R.S. FIXTURES.

I CONCEIVE that your object in opening your columns for this discussion is not merely that existing and proposed arrangements should be freely criticised, but also that other plans should be suggested, and in their turn thrashed out. Indeed, herein lies the immense value of journalistic discussion. The time flies so rapidly at the committee and business meetings of large societies that there is really no time to bring forward and fairly discuss and decide upon new plans of action, but if the pros and cons have been freely argued in the press, then when a proposition comes before a committee a decision is readily arrived at.

In this spirit I venture to suggest for discussion an arrangement of the N.R.S. Shows which I think would tend to remove the dissatisfaction which many growers undoubtedly feel at present, without involving any hardship to those whom the present fixtures suit. The regulations of the N.R.S. call for the holding of Metropolitan and Provincial Shows, but there is no rule that the former shall always take precedence of the latter in point of date, and my suggestion is that such precedence should be taken alternately by each of these Shows year by year. That is to say, as the Metropolitan Show is fixed for Saturday, July 1st, and the Provincial for Thursday, July 13th this year, let them change order in 1894: the Provincial taking place on the first Saturday in July, and the Metropolitan on the third Saturday (as we are given to understand the Crystal Palace Company insist upon a Saturday). The crux of the divergence of feeling as to dates is that the provincial Show is universally regarded as far inferior in importance to the Metropolitan, and the late growers feel that while the present dates are adhered to all possibility of the superior honour of a win at the Crystal Palace is confined to the earlier men; but if every other year the important Show could be held on the later date this feeling would be removed. I hope that this idea may at least be thought worthy of consideration and discussion by those of your readers who are interested in the matter, and that some plan may be decided upon which will increase the membership of our Society and multiply exhibitors of our national flower.

I have no remark to make upon the letter from Croydon which appears on page 151. I have taken part in various discussions in your columns for some eighteen or twenty years now, but there are two things which I have never done—I have never been guilty of a personal attack upon a correspondent, nor have I ever stooped to reply to one. When such practices become essential to journalistic controversies I shall retire from the field in favour of those whose inclination lies in that direction.—J. B.

[We are requested to state that this letter was written prior to the publication of our issue for March 2nd.]

#### THE PARENTAGE AND NATIONALITIES OF ROSES.

I FIND the parentage or pedigree of Roses extremely fascinating. It is for example most interesting to know that Baroness Rothschild is the gracious mother of Merveille de Lyon; that exquisite Augustine Guinnoiseau is an almost white La France, possessing by inheritance all the attributes of that queenly Rose; that the superb Jeannie Dickson, though an Irish production, has been derived from Marie Finger and Baroness Rothschild: that to Etienne Levet and the Countess of

Rosebery may be attributed (with full permission of their eminent raisers, the Messrs. Cocker of Aberdeen) the origin of the Duke and Duchess of Fife; that La Belle Lyonnaise owes its attributes to the immortal Gloire de Dijon; and that Marguerite Dickson (gold medalist of the National Rose Society, and probably the finest Rose that has come to us from the Emerald Isle) is a beautiful daughter, imperial in her majesty, of Lady Mary Fitzwilliam and Merveille de Lyon.

Nothing unfortunately is known of the parentage of the Duke of Edinburgh, which may perhaps be justly regarded in virtue of its universal popularity as the representative English Rose, unless that it was raised from seed along with some others of almost equal fame by Mr. William Paul of Waltham Cross in 1868. I am curious to know the origin of the Mrs. George Paul, a magnificent Hybrid Bourbon Rose of immense substance, and growing to a height of 4½ feet, which I have obtained from Mr. Prince of Oxford, one of the most successful, so says the Dean of Rochester, of Rose cultivators. I understand that Mrs. Paul has won several first-class certificates, likewise the gold medal of the National Rose Society. It is manifestly a valuable addition to modern English Bourbon Roses, which do not constitute a very formidable class from a numerical point of view.

I should perhaps have mentioned, when speaking of the parentage of highly popular Roses, that Souvenir d'un Ami is the parent of Souvenir de S. A. Prince, of whose remarkable attractiveness as a pure white Tea Rose of exquisite beauty nothing need be said.

The following is what may be termed a list of nationalities:—

England, Duke of Edinburgh.	Scotland, Duchess of Fife.
Ireland, Marguerite Dickson.	Holland, Moss Rose.
France, Maréchal Niel.	Italy, Félicité Perpetué.
Austria, Harrisoni.	China, Blush Rose.
Persia, Persian Yellow.	Japan, Rosa rugosa.

— DAVID R. WILLIAMSON.

#### NEW FRENCH ROSES.

NOTWITHSTANDING the very meagre results during the past few years as far as the French Rose growers are concerned they do not seem to be any way inclined to reduce the lists of novelties (?) which they put before those who I fear have no eyes to see or ears to hear all the sweet and pretty things that are brought before them. As usual we have a list of some sixty or seventy Roses, all of which, if we are to believe the descriptions, are most desirable; but the burnt child dreads the fire, and those who have burnt their fingers in years past are not likely to venture on the operation again; in fact, I very much wonder who are they who do venture the first year to buy in these 25 franc a-piece Roses. I have spoken to many growers, but they all shake their heads, and say "Not for Joe." They are unwilling not merely to pay this sum for these much-vaunted novelties, but also to spend a year on propagating, and then, perhaps, after all to have to burn them. There are no French amateurs to buy them, and yet I do not suppose they would go on raising and distributing them if they did it at a loss; they are very economical and grudge any outlay that is not remunerative, and hence I must suppose that somewhere or other they are disposed of, or at least some of them.

Through the courtesy of Messrs. Ketton of Luxembourg I have received the list of novelties announced for this season—*ie.*, the autumn of 1892 and spring of 1893. In looking over it there are some things very noticeable, the absence of some names we have been accustomed to see in such lists. I do not see either of the Verdiers, one of them at any rate, the most liberal sender out of new varieties. I imagine that Kettons, with their usual care, have not omitted any from their lists, and can, therefore only conclude that they have nothing to send us. Then again those who have been in the habit of sending out a good many are contented with one or two, Guillot, Ducher, Schwartz, for example, while those who keep up the ball are growers who are not the raisers of any exhibition Roses in our N.R.S. lists. Another curious feature in the lists of novelties sent over of late years is the very great proportion of Tea Roses. Thus in the lists for the present year there are forty-nine Teas, eight Hybrid Teas, and sixteen Hybrid Perpetuals. Either the raisers have found out how such Teas have advanced in favour of late years, or they found it hopeless to improve on the H.P.'s we already have, and so devote their energies to the Tea sections; but even here can we flatter ourselves that we shall see flowers to beat the favourites we already have. Ernest Metz may be and is good, Cleopatra pretty, and Madame Hoste useful; but will they lower our estimation of Souvenir d'Elise, Comtesse de Nadaillac, or Catherine Mermet? It may be there is some undiscovered pearl in these new Roses, but the experience of the last few years is not encouraging. But now let us see what they offer.

#### TEAS.

- 1, *Antoine Gauret* (Rebout).—Coppery salmon shaded with rose; very large, double, free flowering, and very sweet.
- 2, *Archduc Joseph* (Nabonnand).—Bright rose, centre lovely copper, the borders of the petals paler; very large, very full, cup-shaped, with pointed bud.
- 3, *Baronne Berge* (Pernet père).—Half of the petals light rose, the centre light yellow, medium size, free flowering, and sweet.
- 4, *Baronne d'Estrange* (Lemarque).—Light rose colour shaded with dark coppery rose, with salmon and yellow; very large, double, globular.
- 5, *Baronne J. B. de Morand* (Widow Schwartz).—Yellowish white, flesh colour, shaded with light rose, yellow guard petals, long foot-stalks.

6, *Beauté Inconstante* (Jos. Pernet, Ducher).—Orange red, reverse carmine, on the reverse side carmine shaded with yellow.

7, *Catherine Fontaine* (Liabaud).—Creamy yellow, large, full, the bud very long, and striped with dark rose; very sweet scented.

8, *Comtesse de Breteuil* (Joseph Pernet, Ducher).—Rosy salmon on the outside, the centre dark peach, almost rose, lined with dark chrome yellow; large, very full, cup-shaped; footstalk firm and upright.

9, *Comtesse Festetics Hamilton* (Nabonnand).—Light carmine red flower, reflexed with copper; outside petals much darker, and coloured on the edges, very large, very full; bud very long, flowers singly, not in bunches.

10, *Comtesse O'Gorman* (Nabonnand).—Flowers china rose, base golden, medium size, half, long buds.

11, *Directeur René Gerard* (Pelletier).—Canary yellow in the centre, back of petals flesh colour, and china rose colour, shaded with magenta on the edges; very double, opening well, very sweet.

12, *Erzherzogin Marie von Ratibor* (Taske).—What a lovely name! Imagine some of us trying to mouth it out for the judges. Capucine red, at the base yellow; semi-double, generally flowering singly, opening well, and sweet.

13, *Erzherzog Franz Ferdinand* (Souper & Notting).—Outside petals base red, inner petals gold colour, centre carmine lake, with the reverse golden, very full, cup shaped, very sweet; a seedling from Adèle Jongait and Adrienne Christophle.

14, *Fata Morgana* (Drogemeller).—Satiny rose, often deeply shaded with flesh colour; variable, very full, flat.—D., Deal.

(To be continued.)

#### THE ROSE CONTROVERSY.

I DO not wish in any way to re-open the recent controversy, which I am very pleased to find is now definitely, and I trust amicably, closed. Without the following brief explanation the question of "veracity" appears to me to be left in a very unsatisfactory state on both sides. The completeness of the lists of members issued by the N.R.S., for which I am in a great measure responsible, would also seem from the correspondence somewhat doubtful. Mr. Grahame tells your readers that he first joined the National Rose Society in 1878, while Mr. Pemberton stated that he could not find Mr. Grahame's name in any of the lists of members he had by him before 1889. Both of these conflicting statements will, however, on reference to all the lists of members which have been published by the Society, be found to be perfectly accurate, for they show that Mr. Grahame first joined the Society in 1878, but after a few years ceased to subscribe until the Rose year of 1888-9, when he again became a member.—EDWARD MAWLEY, *Hon. Sec. National Rose Society.*

#### CULTURE OF PLUM TREES IN POTS.

THE Plum is one of our hardiest, heaviest cropping, and most useful fruits. The fruit, however, is seldom grown to such perfection as to command full appreciation of its merits. In the first place, little, if any, attention is given to the early thinning of the fruits of outdoor trees, consequently the trees are overburdened, and so weakened by the crop that they only bear about once in three years. The fruit, moreover, is not only small in size and indifferent in quality, but is seriously deteriorated for preserving purposes and drying. In the second place, outdoor Plums are frequently spoiled by inclement weather at the time of the fruit ripening, and so cracked as to be uninviting and not unfrequently unwholesome. The principal objects, therefore, of growing Plum trees in pots are: 1, To insure a crop of fruit in the fullest perfection; 2, Accelerate the fruit so as to secure an earlier supply; 3, Prolong the season.

To attain the desirable results indicated there is no structure better suited for the purpose than the simple orchard house originally introduced by the late Mr. Thomas Rivers. Its adaptability consists in its being so constructed as to admit of thorough ventilation. The boarded sides are not so close as to entirely deprive the trees of air on frosty nights and on cold days when the house is shut, but enough enters by the "chinks" to prevent a stagnant vitiated atmosphere, and this is essential to a good set of fruit. Provision is, of course, made at the sides for abundant ventilation by hinged boards opening the full length of the house, the roof is glazed with large panes of glass, so that the trees get plenty of light, and the inclemency of our fickle climate is defied. In brief, the orchard house is the exact position for growing Plum trees in pots, as it affords sufficient shelter to carry them safely through our uncertain springs; to insure the perfecting of their crops in cold, dull, wet seasons; preserving the fruit in good condition after it is ripe by throwing off rains and keeping it safe from dew and fogs.

With a proper selection of varieties a supply of Plums, for dessert or culinary purposes, may be had from trees grown in pots in an orchard house from the beginning of July to November. The early and late varieties are invariably excellent in quality, but the midseason sorts do not always finish satisfactorily, the fruit ripening prematurely in hot and dry seasons, and has not the crackling flesh and high quality of fruit ripened in the open air. This applies to all the Gage race and other midseason high quality varieties. The late Mr. Thomas Rivers was aware of this, and pointed it out in his first edition of the "Orchard House" in 1850. He advised trees in pots of those races to be removed

to a warm and sheltered situation outdoors for ripening. That is all very well if the weather be favourable, but if wet it is only placing them outdoors to spoil the fruit. I have not a later edition of Mr. Rivers' "Orchard House" than 1858, and I do not know whether the same thing is still advised, but I have had to deal with Plum trees that were planted out under glass, and have found that in a hot droughty summer the Gage race, with Jefferson and similar varieties, did not finish the fruit satisfactorily, being soft in flesh and poor in flavour. I found the defect was due to insufficient watering, feeding, and air moisture, the rule of thumb not being relaxed so as to increase the atmospheric moisture and ventilation essential to the perfecting of these

FIG. 44.—CZAR PLUM TREE IN A POT.

classes of fruit in hot seasons, and to secure its crackling and rich flavour. This liability is more common in the southern than in the northern parts of the kingdom, there the fruit is not half appreciated, nor in cold and wet localities, except when it is produced by trees grown against a sunny wall, or had from those grown under glass.

Some of the culinary Plums attain to a great size when properly thinned, and a quality fitted for the dessert. Czar, shown in the illustration (fig. 44), answers either for dessert or kitchen use, and the dessert varieties make the sweetest pies, puddings, and preserves, but some tastes prefer those more or less tart. The subjoined list caters for both, and the varieties are named in their order of ripening.

*Dessert Varieties.*—Early Favourite, Oullins Golden, De Montfort, Denniston's Superb, Early Transparent Gage, Jefferson, Green Gage, Purple Gage, Transparent Gage, Kirkc's, Coe's Golden Drop, Ickworth Impératrice.

*Kitchen Varieties.*—Early Prolific, Czar, Heron, Belgian Purple, Prince Englebert, Washington, Victoria, Pond's Seedling, White Magnum Bonum, Monarch, Archduke, Grand Duke.

In a subsequent issue I will refer to the culture of Plums in pots.—G. ABBEY.

**EVENTS OF THE WEEK.**—The ensuing week will not be such a busy one in horticultural circles as that just past. The first spring Show of the Royal Botanic Society will be held on Wednesday, March 22nd, at Regent's Park, and apart from this but little of horticultural interest, other than the auction sales, will take place in the metropolis.

— **THE WEATHER IN LONDON.**—Last Sunday the thermometer in the shade in the metropolis rose to 64°, or 14° above the March average. This was the highest temperature recorded so early in the season for twenty years, the nearest approach to it being in 1884, when the maximum temperature of 63° was registered on March 15th. In twelve years out of the past twenty the thermometer in London failed to reach so high a point as that on Sunday at any time in March, and in seven of these years it never rose as high as 60°. At the time of going to press it is also fine and mild.

— **WEATHER IN THE NORTH.**—Bright and dull days have alternated during the past week. On two nights the thermometer fell to the freezing point. Strong westerly winds have prevailed, and the weather has been cold, even during the day, the nights being now and then bitterly so.—B. D., *S. Perthshire*.

— **THE ROYAL GARDENERS' ORPHAN FUND.**—The annual dinner in connection with this charity, which was announced to be held on the 22nd inst., is postponed by the request of the Chairman (Baron Ferdinand de Rothschild) to Wednesday, 26th of April.

— **THE FORESTRY EXHIBITION.**—We learn that a project is under consideration for having specimens of the trees and shrubs that are grown in the London parks represented at the forthcoming Exhibition at Earl's Court. The object, we presume, is the laudable one of affording the public an opportunity for noting the most suitable kinds for town gardens—an object to which the park authorities may usefully and appropriately contribute.

— **WALKLEY AMATEUR FLORAL AND HORTICULTURAL SOCIETY.**—At the last meeting of this Society Mr. E. Hill read an essay on "Spring Bulbs," dealing with Hyacinths, Tulips, Narcissi, Lachenalias, and Lily of the Valley. The essayist confined his remarks to indoor cultivation, and gave brief lists of the most suitable varieties. Mr. John Haigh, who presided, also discoursed interestingly on the subject.—E. D. S.

— **IMPORTED APPLES AND PEARS.**—According to the Board of Trade returns for the month ending February 28th, 246,728 bushels of Apples were imported during that period, the value of these being £68,552. In the corresponding month of last year 345,845 bushels of Apples were imported, and these were valued at £103,804. The number of bushels of Pears amounted to 1929, at the value of £1290, compared with 2585 bushels for February, 1892, assessed at £1489.

— **PRIZE FOR BOTANY IN ABERDEEN UNIVERSITY.**—At a recent meeting of the Aberdeen University Court—the Marquis of Huntly, Lord Rector, presiding—a letter from Mr. Hector Allan, Sydney, N.S.W., was discussed, stating that a sum of £75 had been given by the late Rev. Robert Collie, Presbyterian minister, New Town, near Sydney, for a botany prize in the University. The court unanimously agreed to accept the money, and a remit was made to the Senatus to draw up the conditions of the prize. It was explained that this was the first endowment for botany, and the hope was expressed that it might be added to.

— **THE OXFORD BOTANIC GARDENS.**—Referring to these gardens a correspondent writes:—"The state of the various buildings in the Botanic Garden is the subject of an elaborate report from the curators, who have called in Sir Joseph Hooker to advise them. Result—a sum of £3500 is required to put things straight, but the expenditure may be spread over several years. The garden is one of the most beautiful spots in Oxford, but, unfortunately, it is not taken very seriously, and the students of botany are few. The University, in the face of falling rents and a possible diminution of internal revenue, will soon have to consider seriously its attitude towards special studies."

— **THE GRAPE ROOM AT SANDRINGHAM.**—The length of the Grape room at Sandringham is 33 feet instead of 23, as stated in the article in last week's issue.

— **DEATH OF MR. J. T. BURNELL.**—With regret we announce the death of Mr. John Thompson Burnell, so well known as a member of the seed firm of Waite, Burnell, Huggins & Co. of Southwark Street, London, and Paris. Mr. Burnell was in his fifty-ninth year.

— **GARDENING APPOINTMENT.**—Mr. W. Dolling, late head gardener at Whitehill, Newton Abbot, has been appointed head gardener to E. F. Tueby, Esq., Manor House, Ashton, Chudleigh, Devon.

— **FOREIGN POTATOES.**—During the past month the importation of Potatoes from abroad were as follows:—Germany, 5287 cwts.; France, 112,608 cwts.; Channel Islands, 435 cwts.; and various countries, 101,915 cwts.

— **DEATH OF MR. C. P. JOHNSON.**—We regret to hear of the death of Charles Pierpoint Johnson, author of "British Wild Flowers" and "Useful Plants," &c., son of the late Mr. Charles Johnson, for many years Professor of Botany at Guy's Hospital. Mr. Johnson died on Monday, March 6th.

— **GUILD OF KEW GARDENERS.**—We are requested to draw attention to the notice of the above Society which appeared in our columns a few weeks ago. All Old Kewites who have not yet sent in their names and address, for publication in the Guild's *Journal*, should do so without delay.

— **EDINBURGH BOTANIC GARDENS.**—We are informed that in a class of upwards of 300 students at the Edinburgh University Botanical Examination, held by Professor Balfour, at the Botanic Garden, Mr. James Wm. Watt, eldest son of Mr. James Watt, Carlisle, obtained second honours for herbarium.

— **TEIGNMOUTH AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT SOCIETY.**—At the fortnightly meeting of the above Society, held on the 7th inst., Mr. G. Foster, gardener to H. Hammond-Spencer, Esq., read a very interesting paper on "The Cultivation of the Tomato." A discussion followed, in which several members took part.

— **ROYAL BOTANIC SOCIETY.**—The first Exhibition of Spring Flowers will be held at the Society's Gardens, Regent's Park, on Wednesday, March 22nd. The customary classes for Azaleas, forced Roses, hardy flowers, Primulas, Cyclamens, Freesias, and bulbous plants are provided, and miscellaneous exhibits are also mentioned in the schedule.

— **MR. BENJAMIN HURST.**—We understand that Mr. B. Hurst, a nurseryman of Burbach Grove, near Hinckley, has been placed upon the Commission of the Peace for the County of Leicester. Mr. Hurst, who has served on the Leicestershire County Council since its establishment in 1888, is the senior partner of the firm of Messrs. B. Hurst and Son, Burbage Nurseries, near Hinckley.

— **BULBOUS FLOWERS.**—I never remember a season when Snowdrops, Crocus, Lent Lilies, Double Daffodils, and the ordinary single Jonquils gave so good a promise for flower as the present. Whether it was the hot, dry weather experienced during the month of last June I am not prepared to say, but suspect it was the reason. Thousands of these bulbs are growing on grass, and in every instance, even under trees, they give promise of a most abundant flower crop.—E. M.

— **TASMANIAN APPLES.**—It is expected that Apples will during the forthcoming season be imported from Tasmania in larger quantities than in any previous year. To meet the demand for cool space in the mail steamers for the conveyance of Apples, the Orient Company have recently made large additions to the refrigerator holds of the Orient Line steamers which will be leaving during the next fruit season. It is stated that the first consignment of Apples will be brought by the twin screw steamship "Ophir," due to reach England about the middle of April.

— **ALLOTMENTS IN LONDON.**—A correspondent in the "City Press" says:—"The very interesting deputation which waited on the Common Council respecting certain unused land adjoining the Cattle Market at Islington, will give the Corporation another opportunity of doing good to the people of the metropolis. This land has never been utilised for market purposes, and certain working men in the neighbourhood, which is thickly populated by people living in small houses, often with scarcely a backyard, are desirous to obtain allotment gardens on this idle land."

— **WOOLTON GARDENERS' MUTUAL IMPROVEMENT SOCIETY.**—A meeting of the above Society was held on Thursday last at the Mechanics' Institute, Mr. R. Todd presiding. A paper on "Ferns" was read by Mr. F. Ker, who gave a good selection of exotic Ferns with hints as to their respective treatment. The paper was rendered doubly interesting by a large number of dried specimens which Mr. Ker had on view. The usual vote of thanks terminated the proceedings.—R. P. R.

— **A GOOD NARCISSUS.**—When paying a visit to the well kept gardens at Hasely Manor a short time since, Mr. Clements pointed with justifiable pride to some well-grown Narcissi. I noticed many fine spikes, but one in particular stood out as a veritable giant among them all. The flower stem was of extraordinary thickness, but still more remarkable were the individual flowers which composed the spike; counting these, fully expanded and opening, there were twenty-two. It would be interesting to know if other cultivators have grown or met with a similar instance of prolific flowering in any of the *Polyanthus* Narcissi. The variety in question was Prince of Wales.

— **DIELYTRA SPECTABILIS.**—In the same garden I noticed some especially good specimens of this grand plant. The fine arching flower spikes were of great length, and the growth having developed regularly on all sides rendered the plants especially suitable for arranging singly in vases, placed in a somewhat elevated position, and I can imagine nothing more useful or beautiful for the purpose.—D.

— **BEDDINGTON, CARSHALTON, AND WALLINGTON HORTICULTURAL SOCIETY.**—The annual Exhibition of this enterprising Society will be held on August 7th. Numerous classes are provided in the schedule, and liberal prizes are offered for various exhibits. A novel feature is the class for the best dinner to be produced at a cost not exceeding 2s. The dinner must consist of meat, and at least two distinct kinds of vegetables, and be sufficient for a man, his wife, and three children. The value of each article must be clearly stated. The prizes of, first, £2; second, £1 10s.; third, £1; fourth, 10s., are presented by Mr. A. Smee, who also offer awards for home-made jams. The classes are open to wives and daughters of all subscribers and members.

— **AUSTRIAN versus CORSICAN PINES.**—Like Mr. Parker (page 192) I have found the value of "Austrians" for shelter from wind. I have also found that Corsican Pines are better wind-resisting trees than many persons think. We have a number of both growing side by side in a rather exposed situation, and they seem to withstand the force of the south-westerly gales equally well. Although the Corsican is credited with being of much quicker growth than the Austrian Pine I do not find it so. Several hundreds of each were planted side by side ten years since, and at the present time both are of the same height—12 feet. The Austrians promise quite as well as do the Corsicans in the matter of growing into timber. In both cases the growth is clean and straight, and indeed all that is desirable.—E. MOLYNEUX.

— **THE GORDON BOYS' HOME.**—I should very much like to support the appeal made by Colonel Walker, the commandant of this home for boys at Bagshot, for plants that may be spared for the lads who have gardens. The boys are gathered from all parts of the kingdom, and are in no sense associated with crime or improper conduct. Rather good conduct allied to poverty is the chief recommendation for admission into the Home. Several of the elder boys under the charge of the bailiff and gardener (Mr. Hale) attended my horticultural lectures at Chobham early in the winter, walking a couple of miles for the purpose regularly. They were very patient, attentive, and interested listeners, and I am sure present first-rate constituents for the making of well trained garden lads, should any readers need such assistance.—ALEX. DEAN.

— **THE NATIONAL DAHLIA SOCIETY.**—The annual general meeting of this Society was held recently at the Hotel Windsor, Mr. E. Mawley, presiding. According to the report, the season of 1892 was not one of the best for Dahlias, though, notwithstanding this, the annual Exhibition was a fine one. The Committee deplore the loss of the late Mr. J. Downie, of Edinburgh. The financial statement showed that the subscriptions amounted to £56 9s., there being also £50 from the Crystal Palace Company and other items. Against this £122 15s. had been distributed in prizes, a small balance remaining in hand. The Rev. Charles Fellowes was re-elected President; Mr. T. W. Girdleston, Secretary; and Mr. E. Mawley, Treasurer. Mr. W. Frost and Mr. R. Dean were added to the Committee, the former in the place of the late Mr. G. W. Phippen. The other members of the Committee were re-elected.

— **THE ROYAL WESTERN HORTICULTURAL SOCIETY.**—This Society held its annual meeting last week at the Plymouth Guildhall, under the presidency of the Mayor, Mr. W. Law. The report stated that the subscribers were to be congratulated on the good work that had been done. There was expended in prizes £118 18s., and there remained a balance to the credit of the Society of £128 9s. 9d. Whilst regretting the resignation of Mr. E. J. Winter Wood as Hon. Secretary, the Committee were glad to report that Mr. John Walling had accepted the office.

— **PRESENTATION TO MR. GEORGE DICKSON, J.P.**—On the 4th inst. the Committee of the Newtownards Horticultural Society presented Mr. G. Dickson, J.P., the head of the firm of Messrs. A. Dickson & Sons, with a testimonial in recognition of the valuable services he has rendered the Society during the past thirty-seven years. The presentation consisted of a silver salver, with silver tea and coffee service, weighing over 300 ozs., and accompanying the gift was a tastefully designed volume, containing the address and signatures of the officers and members of the Committee.

— **KIRKSTALL ABBEY GROUNDS.**—At a recent meeting of the Corporate Property Committee of the Leeds Corporation, plans for the laying out of the grounds adjoining Kirkstall Abbey were considered. Thirty-seven sets of plans were originally submitted. These were reduced to half a dozen by a sub-Committee appointed for the purpose. The Committee eventually resolved to pay the first premium of £20 to Messrs. J. Cheal & Sons, nurserymen and landscape gardeners of Crawley, Sussex. The design submitted by this firm has numerous fine features, and when carried out will render the Abbey and its grounds an attractive resort. The carrying out of this design will involve an estimated expenditure of £3000. The second premium of £10 was awarded to Mr. T. H. Mawson of Windermere.

— **WAKEFIELD PAXTON SOCIETY.**—The programme of meetings for the first quarter, session 1893, is as follows:—March 11th, "Bees and Bee-keeping," Mr. J. Eastwood; 18th, "Legends Respecting Trees and Plants," Mr. A. Batty, Rothwell; 25th, "Plant Adaptation for Fertilisation" (illustrated with lantern diagrams), Mr. J. W. Macpherson, B.A.; April 1st, "Depression in Agriculture," Mr. T. Pitts; 8th, "The Camellia," Mr. J. G. Brown; 15th, "Body and Mind, their Relations," Mr. G. W. Fallas; 22nd, "Deep Cultivation (Importance of)," Mr. W. Hudson; 29th, "Soils and Manures," Mr. H. Crowther; May 6th, "Nature Notes," Mr. G. Bott; 13th, "Garden Pests," Mr. J. Wood, Kirkstall; 20th, "The Rhododendron," Mr. G. Hudson; 27th, "Place Names," Mr. James Reyner. The meetings are held at the Society's room, Westgate, Wakefield, each Saturday evening, commencing at eight o'clock prompt.

#### JOTTINGS FROM MEMORY—EARLY LONDON FLOWERS.

SOME time during December in last year a correspondent wrote from South Devon in the pages of "our Journal" relating on the extreme mildness of the season there, at the same time naming several varieties of summer flowers then in bloom. What thoughts for reflection that note conveyed to me!

Although the end of 1892 was generally mild throughout England until Christmas day, still there were times and districts where unexpected onslaughts had been made on vegetation even in "favoured" localities. Mr. T. J. R. Chalice of Plympton, South Devon, told me that he had experienced more extreme cases of destruction to vegetation by frost in the spring and summer of 1892 than in any year during the twenty-seven years he had been established there as a nurseryman and florist. The warm bright weather of early April had caused most of the nursery stock of shrubs and Coniferae to commence growth, when on the night of Good Friday they were visited with such a frost that crippled everything, and all new wood was checked for the remainder of the year. Both in June and July he said they had had other frosts, and at 5 A.M., September 17th (I had been up all night watching by the bedside of a dying parent) I saw Kidney Beans with icicles hanging from the points of the foliage, and the leaves of Savoy's completely covered with thick hoar frost, which caused them to hang down, as is customary on a severe winter's day, and this was about thirty miles south-west of your correspondent, and within five miles of Plymouth. All Dahlias and similar tender plants were quite blackened and destroyed, and this I found was by no means an isolated case, but extended over a very large area of that beautiful county. At the same time the plants under my charge in the neighbourhood of London, 240 miles distant, had not suffered in the least, and Dahlias (we grow two thousand) and other tender summer occupants of the garden, remained gay until October had far advanced. To me this was a most singular and exceptional climatical contrast.

While crossing from Cowes to Southampton by an early morning boat on November 9th last, there were three passengers on board with

baskets or bouquets of outdoor-grown garden flowers, a large proportion of them being Cactus Dahlias. On inquiry (for I found them very agreeable companions) I gleaned, as I had thought, that these displays could not be general throughout the island, but had escaped injury from frost by being planted in sheltered spots; this would, I think, equally apply to your correspondent's case in fair and sunny Devon. I can well remember over thirty years since how at Teignmouth the *Clianthus puniceus* flowered and flourished with only the protection of a verandah, and that pretty Heath-like shrub, *Fabiana imbricata*, grew and bloomed abundantly year after year without any protection whatever, while Myrtles and Fuchsias made huge bushes, and the Lemon-scented Verbena, *Aloysia citriodora*, covered a large space of the side of a building.

It would be of interest to know how vegetation has fared there this winter since the time your correspondent penned his note. In London since then we have had for a time some very severe weather. For quite a month the ground was sealed against all garden operations, and with me the thermometer registered twice in the first few days of the new year 25° of frost, the ice on the lake being more than 7 inches in thickness, and skating was general for thirteen days. Notwithstanding, I am pleased to be able to record that comparatively little damage was done to trees and shrubs, although some of them still carry a brown and scalded appearance, amongst which may be named Golden Hollies, *Elæagnus*, *Phillyreas*, *Euonymus*, *Cotoneaster microphylla*, and several of the *Berberis*; but all these will recover their former beauty as new growths are made by warmer weather. The *Escallonia*s I am afraid, are past recovery, but these should never be relied upon in this latitude, and can by no means be recommended for cultivation in or near London.

But how wonderful Nature is! Scarcely had the frost gone from the ground when that harbinger of spring, the Winter Aconite, *Eranthis hyemalis*, came peeping up its golden miniature Tulip-like heads where it has remained proudly in bloom for fully a month now, to cheer by its brightness, and long after the flowers are faded will its fringed collar of elegant foliage remain with us fresh and green. Bulbs of this plant planted during the autumn are not so early in blooming as those that have not been disturbed but left to nature to ripen and die down in the ground where they are required to bloom another year. They can be bought very cheaply, so that I wonder they are not more generally grown. Closely following the *Eranthis*, the Snowdrops were found pushing their way with their little white flowers compressed between the foliage. They are well known and a serviceable favourite with all. Then we have the Hepaticas, a most pleasing and attractive family, especially on days when we are favoured with a glimpse of sunshine, the warmth of which causes the flowers to fully expand and command admiration. *H. angulosa* is a much larger flowering variety than the common form, but all are worthy of extensive cultivation. Pressing hard on the above, we have various varieties of Crocus and Scillas, all adding their modest share of beauty to other attractions.

I often have to deplore the destruction of the Crocus by sparrows, but it is the old old tale. *Saxifraga Burseriana*, of which I possess only two small plants, exhibited its scarlet buds while the frost was yet with us, now its white flowers are fully expanded. *S. oppositifolia* is in bloom, and also *S. crassifolia*, with its dense masses of pale rose flowers, half hidden beneath its large and leathery foliage, as if seeking protection from the cold March winds. *Daphne mezereum*, growing on the rockeries and elsewhere, are now in full flower, enhancing its leafless and otherwise rigid bare stems with numbers of brilliant red, white, and pink blossoms, and coming into bloom so early in each year is both showy and welcome. *Rhododendron præcox* is a very pleasing plant for the rockery, both in habit of growth and brilliancy of flower, but too frequently the blossoms expand in ungenial weather and get punished; but if only cultivated for its habit, its foliage, and its profuse bursting buds (in which undeveloped state it is sweetly pretty) it is worthy of a place, and of all that can be said in its favour. *Andromeda floribunda* is also stretching out its Lily of the Valley like blossoms, while *Erica carnea* is literally covered with its pale rosy flowers; this should be grown very plentifully, either as isolated tufts or as an edging around *Rhododendron* beds. *Jasminum nudiflorum* is expanding its bright yellow flowers, as gay and as striking as it can be found in December, mocking the extreme frost, which held it in check and prevented it from spanning the old and the new years, as it often does, contrasting then in beauty with the scarlet berries of the Sweet Briar and *Cotoneaster Simmondsi*, the berries of both of which have long since been taken for food by our feathered songsters. *Cydonia japonica* on a wall has already opened some flowers, while this and other varieties grown in beds or borders are boldly forming their flower buds to furnish bloom ere long. The male plants of *Aucuba* are also in flower. *Pulmonaria officinalis* and *Arabis alba* are just commencing to bloom, as also are *Polyanthus* and the common Primrose; the last two are well suited for spring town gardening, and as we devote a large space to the cultivation of the Primrose, its magnificent if though simple display recalls memories back of bygone days, when I used to travel some lone country lane in fair Devon.

Nature, again, equally asserts her powerful influence over the lofty forest and other trees as well as the most deciduous shrubs, showing how sensitive they all invariably are to light and warmth. The catkins of several varieties of Willows calls for a burst of admiration; the earliest form with me is a variety known here as the Bitter Willow, which, I think, is *Salix monandria*. Then we have next the Weeping Kilmarnock and *Salix rigida pendula*, hanging thickly studded with their light, downy catkins that, when viewed from a distance may be pardonably

mistaken for flower buds. A variety of pendulous Poplar has very curly and fluffy long catkins, while the same dropping from the Hazel and the Birch are all very interesting.

Higher aloft it will be found that the lofty Elms are thickly studded with small, singular, if somewhat unattractive, flowers.

The uppermost buds of *Rosa rugosa* and several other sorts are almost in leaf, while all the varieties of *Pyrus*, Lilacs, Ribes, and several varieties of the deciduous *Spiræas* are fast pushing their latent buds, affording all interested a host of wonderful pleasures for study, and, verily, in the words of the poet, we may all soon exclaim—

“Spring, sweet spring, is the year's pleasant king.”

—J. W. MOORMAN, *Dulwich Park*.

## USEFUL GARDEN FLOWERS.

WHILE such popular plants as Stocks, Asters, Phlox, Marigolds, and others generally grown, are indispensable in gardens, there are others which ought not to be overlooked. *Mathiola bicornis*, or the Night-scented Stock, as it is often more commonly called, is a charming plant, deserving of a place in every garden, not so much on account of the beauty of its flowers, which are of a pale lilac colour, and partially closed in the daytime, but for the deliciously fragrant perfume they emit in the evening, especially after a shower. The plant succeeds best when the seed is sown in patches or clumps on the borders where required for flowering. It is surprising that this fragrant annual has not become a general favourite.

Then we have the *Nemophilas*, remarkably free flowering annuals. There are several varieties, but I think *N. insignis* is one of the best and most useful. It is of a neat, compact habit, with sky blue flowers with a white centre. The *Nemophilas* are of very easy cultivation, and well adapted for the rockery or as edgings to beds and borders, or any position fancy may suggest. It is the best plan to sow the seed where the plants are intended to flower, taking care to thin them out as soon as they are large enough. This is one of the most charming of common garden flowers.

Purple and white Rockets (*Hesperis matronalis alba plena* and *Hesperis purpurea plena*) are, although well known, seldom met with. This is very singular considering that they are as beautiful and sweetly scented as the much-prized Stock. They last in bloom a great length of time, and the flowers are useful for cutting. I should advise all lovers of hardy flowers to obtain a few plants as soon as possible. Propagation is easily effected by division of the roots or by cuttings.

For mixed borders the *Achilleas* deserve a prominent position, and their pure white double flowers are valuable for cutting purposes. *Aubrietia Leichtlini* is a charming little plant for the rock garden, and is sure to become a favourite wherever known. *Dictamnus fraxinella* and *Dielytra spectabilis* cannot be too highly recommended. *Doronicum plantagineum* is, I think, one of the most effective spring flowering plants in cultivation, and few plants can excel the splendid display caused by this when its countless numbers of large yellow flowers are fully expanded, each bloom being from 3 to 4 inches in diameter. *Rudbeckia Newmani* is most effective in the autumn. It will thrive in almost any soil or situation, and is of very free growth, and produces abundance of golden yellow flowers with black centres, useful for cutting, and lasts a long time in water. I must not close this short note without mentioning *Anemone japonica*, *Zauschneria californica*, and *Centaurea montana*, for the various parts of the flower garden, besides being indispensable where a continuous supply of cut flowers are in demand.

—GEO. PARRANT, *Ashby Lodge Gardens, near Rugby*.

### CULTURE OF PERISTERIA ELATA.

ALTHOUGH introduced from Panama in 1826, this Orchid when in flower and well grown even now commands attention and admiration. As its cultivation is carried out very successfully with us, my experience might be of interest to readers of the Journal. It is useless to expect weakly pseudo-bulbs to flower. What is wanted are firm and large pseudo-bulbs, and success in flowering, if the cultural details are closely followed, is assured.

Plants in small pots will now be starting into growth, and if they are taken in hand at once, will by the end of the season have made rapid progress, and developed some good bulbs. Have a compost prepared consisting of two parts fibrous loam, with all loose soil shaken out, one part good peat, the remaining part being made up of soft red sandstone, broken up to about the size of walnuts, coarse silver sand, and some chopped sphagnum moss. Mix the whole thoroughly, and have it in a fairly moist condition. Then prepare some clean pots, and well drain them to a depth of

from 2 to 3 inches. On the drainage place the rougher portions of the compost, and fill up until there is sufficient room left for the base of the bulbs to be level with the rim of the pot. Put a small stake to each, so as to keep them steady until sufficiently advanced to take care of themselves. Remove to a temperature of from 60° to 70°, and syringe frequently about the pots, taking care not to sour the soil before the roots have made some progress.

When the thick fleshy roots can be discerned making their way into the new compost top-dress with a few good pieces of lumpy peat and loam, placing small lumps of sphagnum moss where available. When the top-dressing is completed the base of the bulbs should just be on a level with it. As the season advances copious supplies of water may be given, and to plump the bulbs up thoroughly apply weak liquid manure twice a week. When the winter approaches, and the bulbs seem to have stopped growing, water may be withheld altogether, for it is only by a thorough season of rest that this Orchid can be induced to flower, and it is just at this stage that so many failures occur through not withholding water from them.

In early spring the flower spikes may be seen pushing from the base of the stronger pseudo-

every year, in efficiently drained pots, using about equal parts good fibry peat and sphagnum moss with a few small potsherds and a little fine charcoal being added, making the whole quite firm and keeping the plants well up in the pots.

The plants require plenty of heat and atmospheric moisture, and being kept uniformly moist at the roots during the growing period and until the individual growths have developed their last pair of leaves. They should then be suspended from the rafters in a dry airy house to mature their growth, water being gradually withheld from the roots. The temperature of a late vinery would suit the requirements of the plants admirably, first making sure that they are perfectly free from mealy bug before putting them in a vinery. The plants may be introduced into a warm house early in January for flowering in March.—H. W. W.

#### CYPRIPEDIUM × PENELAUS.

ONE of the finest hybrid *Cypripediums* raised during the past year or two was that exhibited by Messrs. James Veitch & Sons at the meeting of the R.H.S. on January 17th under the name of *C. Penelaus*. It was the result of a cross between the distinct variety of *C. caudatum*

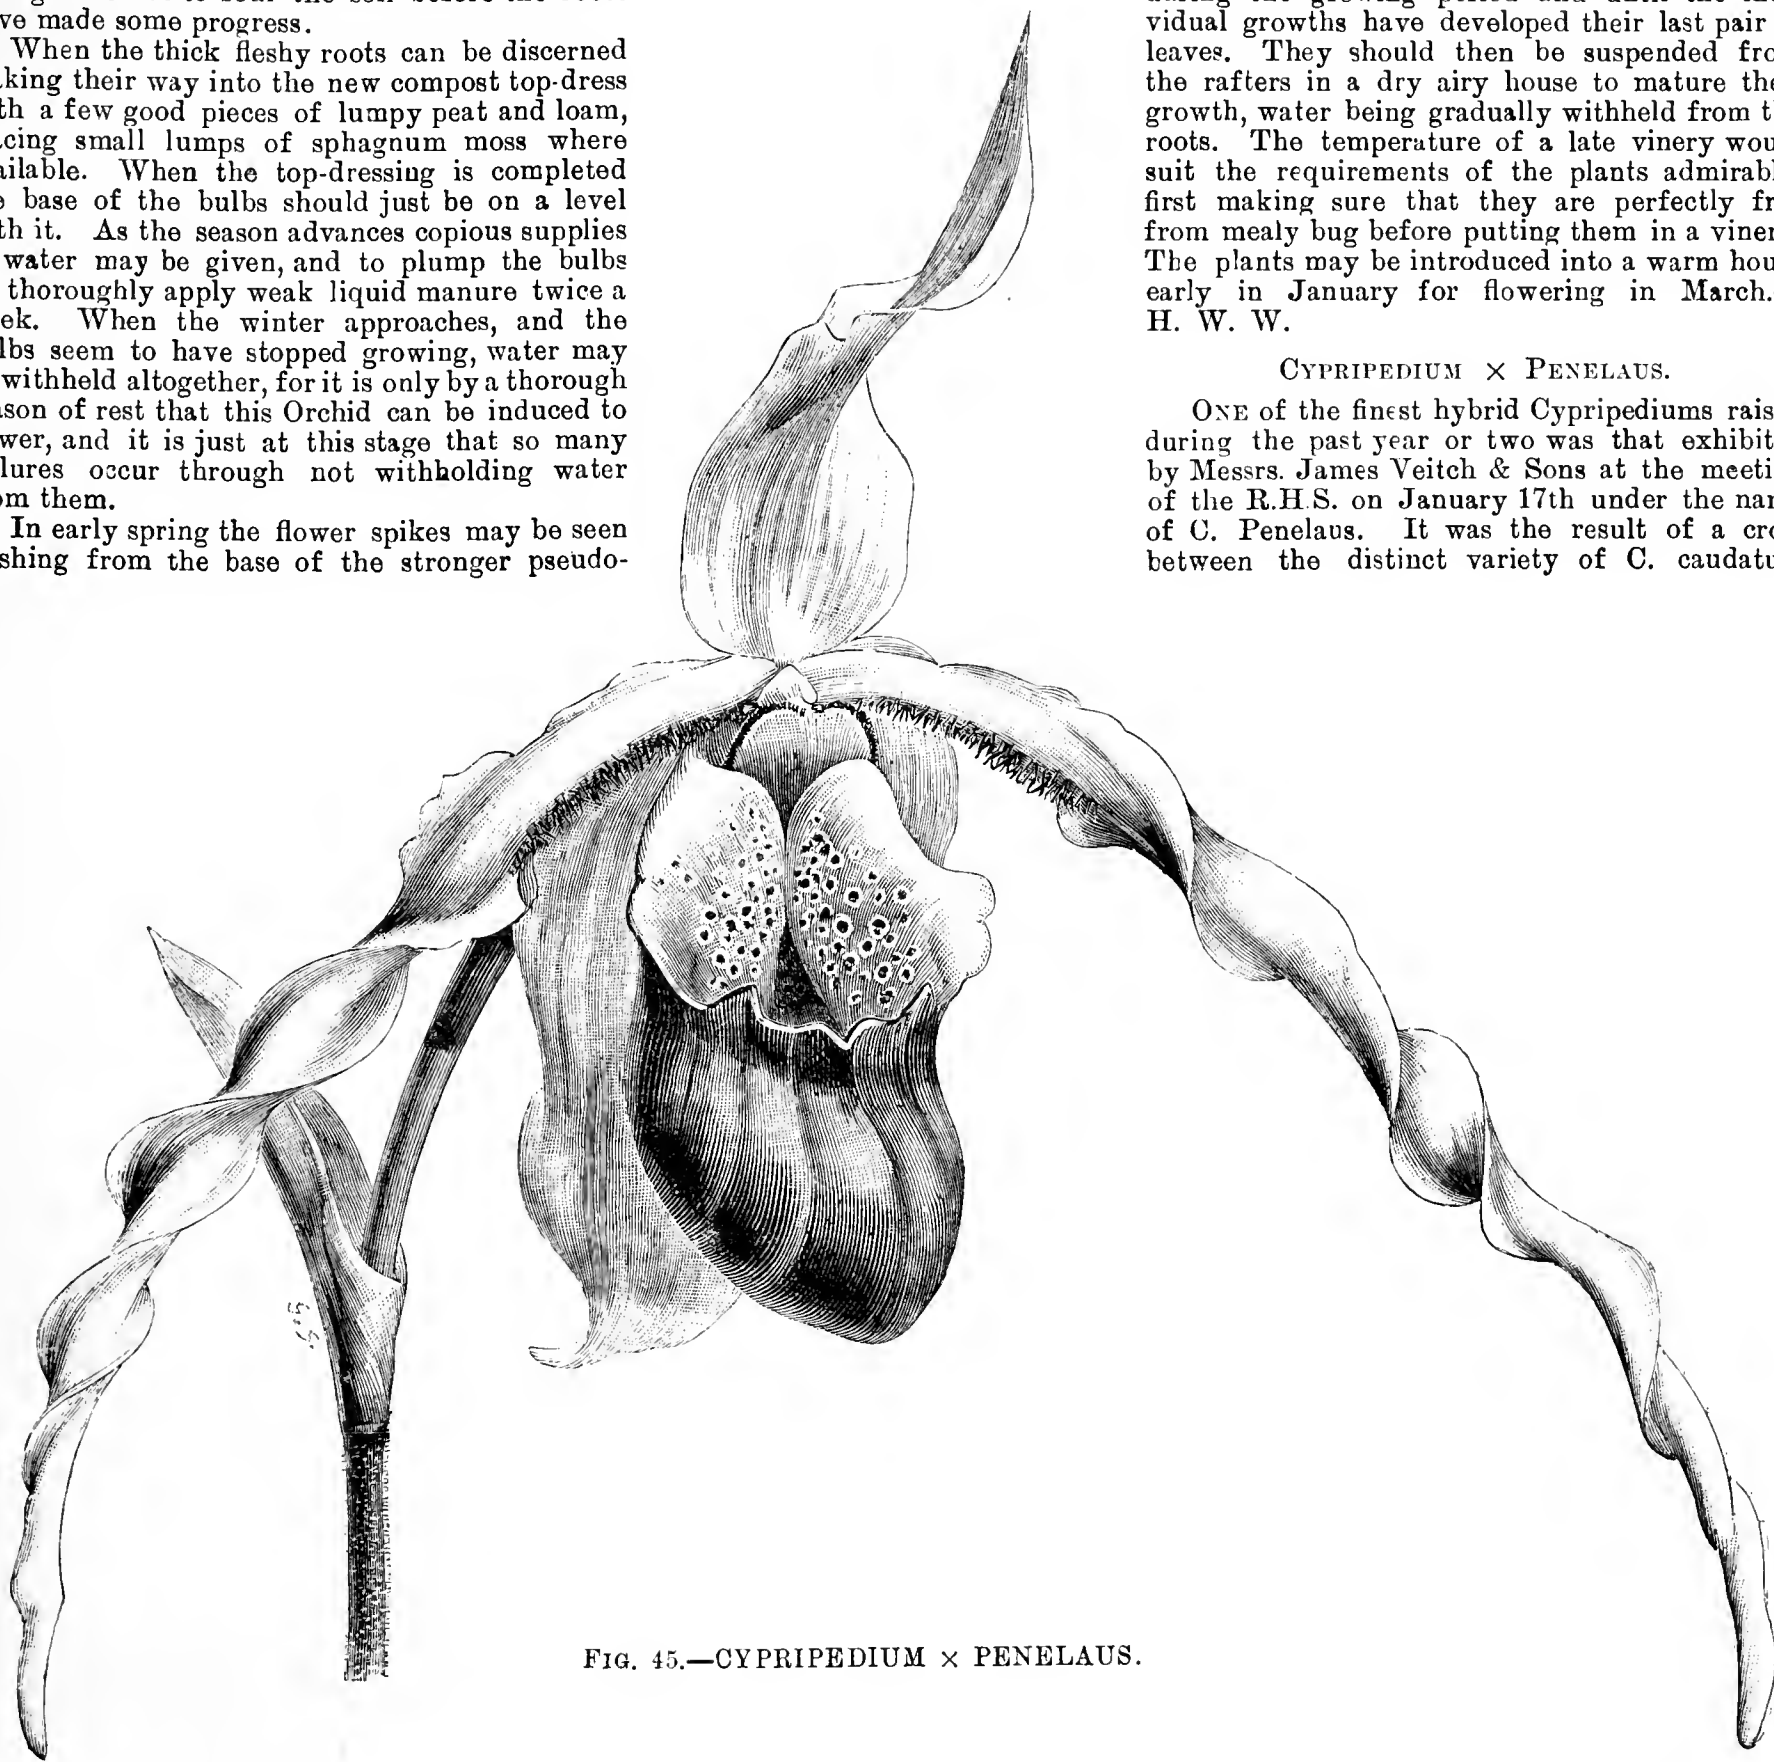

FIG. 45.—CYPRIPEDIUM × PENELAUS.

bulbs, and until these get far enough advanced to discern them from the growth there should be absolutely no more water given than what will prevent the plants shrivelling. By following this system of culture we are able to flower this delightful Orchid every season. White scale often attacks the foliage. Sponging with a little softsoap and water will soon remove it, but care should be used, so as not to damage the leaves.—R. P. R.

#### DENDROBIUM DEVONIANUM.

PLANTS of this pretty deciduous *Dendrobium* growing in 4½-inch and 6-inch pots, and suspended from the roof, are very effective. One shoot of a plant I have has forty expanded flowers extending over a length of 2 feet. The flowers are very pretty, the sepals and petals being creamy white streaked with rosy purple, and the lip being white, beautifully fringed and edged with rosy purple, and having two orange spots, one on each side, at the base. The plants should be potted when finished flowering, not necessarily

named *Lindeni*, with its long, peculiar lip, and the well-known *C. calurum*, the former being the pollen and the latter the seed parent. Their union was a happy idea on the part of the hybridiser, for the result could hardly fail to be distinct and interesting, if not beautiful. *C. Penelaus* is all three. One of the most remarkable features of a noteworthy flower is the lip, which does not follow the peculiar structure of *C. caudatum* *Lindeni*, but is large, full and massive, in colour a bright greyish rose. The dorsal sepal is long, narrow, and pointed, greenish-yellow in hue. The petals are extremely beautiful; they are long, drooping and twisted, soft rosy pink in colour, and impart a most graceful appearance to the flower. It will be gathered that the colouring does not partake of the "harmony in green and brown" type, but rather classes it with the select number of richer coloured forms, of which *C. Sedeni candidulum* is one of the most familiar examples. The new hybrid has, however, a much finer flower than that favourite *Cypripede* can boast. Fig. 45 represents it.

## DENDROBIUMS IN SMALL POTS.

I ENCLOSE a photograph of a *Dendrobium nobile* that is now in bloom in the stove at Cragg Royal, Rawdon, the residence of A. Jacobs, Esq. (gardener, Mr. T. Newbould). It is grown in a 6-inch pot, and has over 200 blooms on it. In the same house is another plant of *D. nobile*, with about the same number of blooms on it, but is grown in a 7-inch pot. I should like to know if there is any account of equally fine specimens grown and bloomed in such small pots.—W. OLIVER.

## ROYAL HORTICULTURAL SOCIETY.

MARCH 14TH.

THE Drill Hall on the above occasion presented a bright appearance, the large building being well filled with spring-flowering plants. Orchids were well represented. Fruit was not extensively shown.

**FRUIT COMMITTEE.**—Present: Philip Crowley, Esq. (in the chair), Rev. W. Wilks, and Messrs. T. F. Rivers, G. Bunyard, J. Cheal, Harrison Weir, T. J. Saltmarsh, G. Norman, J. Smith, J. Hudson, H. Balderson, G. Wythes, E. Burrell, G. Sage, W. Bates, G. Goldsmith, G. T. Miles, J. A. Laing, G. W. Cummins, C. Ross, and J. Wright.

Mr. Charles Ross, Welford Park, Newbury, sent a seedling Apple, medium sized, flattish, greenish yellow, heavily netted with russet, but was not considered equal to existing dessert varieties, and no award was made.

Mr. Owen Thomas sent from the Royal Gardens, Windsor, good bunches of Black Hamburg Grapes, grown in a house which was closed on November 1st and heat applied November 15th. The berries were good, but not quite ripe. These were the first new Grapes brought before the Committee this year, and an unanimous vote of thanks was accorded. Mr. Wm. Smythe, The Gardens, Basing Park, sent bunches of Mrs. Pince Grape (shrivelled), also of Alicante and Lady Downe's, fresh and good, the Alicantes especially (cultural commendation).

The Cape Fruit Syndicate sent through Messrs. Draper & Co., Covent Garden, fine bunches of white and smaller bunches of coloured Grapes, but they did not arrive in tempting condition. In quality they were better than the Almerian Grapes, and might possess commercial value in England if they arrived in a more presentable state. Williams' Bon Chrétien Pears from the Cape were so advanced in decay as to be practically worthless. Three Cape Melons were also sent, very large, oval, well netted fruits. One of them, a green-flesh, was of good marketable quality, the others over-ripe.

Mr. J. Miller, gardener to Lord Foley, Ruxley Lodge, Esher, sent a box of La Grosse Sucrée Strawberries, rather small, but ripe, and a vote of thanks was awarded. Mr. Leech sent ripe fruits of Ladybird Tomato, small and corrugated, very unlike the condition of the variety in summer and autumn.

Mr. E. Beckett, The Gardens, Aldenham House, Elstree, sent samples of what he terms the "New Forcing Lettuce" Harbinger, from seed sown September 16th, 1892, but the produce was not particularly crisp and succulent, and no award was made. Mr. G. Monro, Covent Garden, sent several baskets of Mushrooms, grown by Mr. S. Hardy, Ash House, Parsons Green, firm, good samples, for which a bronze medal was recommended. An accompanying note stated that 3764 lbs. were cut from outdoor-beds during the past seven weeks.

**FLORAL COMMITTEE.**—Present: W. Marshall, Esq. (in the chair), Messrs. C. T. Druery, H. B. May, Richard Dean, Geo. Stevens, C. F. Bause, Geo. Gordon, R. B. Lowe, C. Jefferies, W. C. Leach, J. Jennings, C. E. Pearson, W. Furze, W. Bain, C. J. Salter, Ed. Mawley, C. E. Shea, J. D. Pawle, Jas. Walker, J. Bennett-Poë, T. Baines, Geo. Paul, H. Turner, Peter Barr, Robert Owen, John Fraser, J. H. Fitt, and Rev. H. H. D'Ombraim.

Messrs. J. Laing & Sons, The Nurseries, Forest Hill, S.E., staged a very fine group of greenhouse flowering and foliage plants, amongst which were pieces of *Dendrobium crassinode giganteum* and *D. Wardianum*. Some *Clivias* in this group were very striking, as also were the Ferns and Palms (silver Flora medal). Messrs. Cutbush & Son, Highgate, exhibited a magnificent group of miscellaneous plants, including Azaleas and Ericas in variety, and Begonia Gloire de Sceaux, recently figured in our columns (silver Flora medal). A good collection of herbaceous flowers was shown by Messrs. E. D. Shuttleworth & Co., Fleet, Hants, who also had a large group of miscellaneous flowering and foliage stove plants (silver Banksian medal). A magnificent group of Cyclamens was exhibited by Mr. J. Odell, Gould Green, Hillingdon. The plants in this group were finely grown, and covered with flowers (silver Flora medal). Mr. W. R. Newport, Hillingdon, exhibited some well grown plants of Model White Primula. This is a favourite for market purposes, the habit being all that is desired (silver Banksian medal).

A collection of hardy flowers was exhibited by Mr. T. S. Ware, Hale Farm Nurseries, Tottenham. The Narcissi in this group were very fine, more particularly *N. poeticus ornatus* and *maximus* (silver Flora medal). Messrs. Paul & Son, Cheshunt, showed a charming basket of herbaceous plants, which included excellent examples of *Hepatica triloba*, *Primula denticulata*, and *Sisyrinchium grandiflorum*. For a pan of *Scopulina Fladnichiana* the same firm were accorded an award of merit (see below). Amaryllises were also exhibited by the same firm. The varieties included *Sirius*, *Salvator Rosa*, Mrs. Henry Wood, Mars, and *Acme* (silver Banksian medal). Messrs. P. Barr and Son, King Street, Covent Garden, staged a group of hardy flowers,

including *Chionodoxa Lucilliae*, *Fritillaria aurea*, *Narcissi*, *Sisyrinchium grandiflorum*, and others (bronze Banksian medal). From the Royal Gardens, Kew, came a group of hardy shrubs, prominent amongst which were *Prunus cerasiformis* var. *Pissardi*, *Ribes sanguineum* var. *glutinosa*, *Pyrus japonica*, and some varieties of *Rhododendrons*.

Messrs. Wm. Paul & Son, Waltham Cross, exhibited a very fine collection of Camellia flowers, for which a silver Flora medal was recommended. The same firm showed Tea Rose Corinna (silver Flora medal). Mr. P. Perry, gardener to J. C. Fasher, Esq., Middleton Hall, Brentwood, Essex, also exhibited some pots of Roses (silver Banksian medal). Mr. Bain, gardener to Sir Trevor Lawrence, Bart., staged a charming group of winter-flowering Begonias, including *B. odorata*, *B. nitida*, *B. Triomphe de Nancy*, and *B. Triomphe de Lemoine*, to which an award of merit was accorded (see below). Messrs. Jas. Veitch and Sons, Chelsea, showed a grandly flowered plant of *Rhododendron Early Gem*. The plant was a mass of bloom. Amongst the grand Amaryllises sent by the same firm were *Socrates*, *Eldorado*, *Corinna*, *Excellent*, and *Nimrod* (see below). *Corylopsis pauciflora* from Messrs. Veitch & Sons was awarded a first-class certificate (see below).

A silver Banksian medal was recommended to S. C. Zutwycne, Esq., Oakfield, South Eden Park, Beckenham (gardener, Mr. May), for a group of Amaryllises and *Clivias*. Mr. Chas. Brüggmann, Villefranche-sur-Mer, France, was adjudged an award of merit for *Chrysanthemum frutescens Alma Brüggmann*. Mr. J. Douglas, Great Gearies, Ilford, was awarded a vote of thanks for a basket of fine *Cineraria* blooms. Mr. C. Holden, Ealing, staged a small collection of Azaleas, Camellias, and other plants in bloom (silver Flora medal). A basket of Neapolitan Violets came from Lord Foley, Ruxley Lodge, Esher (gardener, Mr. Miller), the flowers being large and fragrant. *Cinerarias* were well represented by a fine collection from Messrs. J. James & Son, Farnham Royal, Slough, the flowers being large and the colours bright (silver Banksian medal). Messrs. Hugh Low & Co. staged, as they have done on former occasions, a collection of hard-wooded plants in flower, these forming quite a feature (silver Flora medal). Some *Clivias* (see below), *Anthuriums*, *Dracenas*, and *Caraguata cardinale* (award of merit) were shown by Messrs. B. S. Williams & Son, Upper Holloway. Amaryllis Greenlands Gem was well shown by Mr. Perkins, gardener to the Viscountess Hambleton, Greenlands. Mr. Leech, gardener to Duke of Northumberland, Albury Park, showed some profusely flowered sprays of *Deutzia candidissima* fl.-pl. G. F. Wilson, Esq., Weybridge exhibited a collection of Primrose flowers of different shades of blue, plum blue, and lavender.

**ORCHID COMMITTEE.**—Present: H. J. Veitch, Esq. (in the chair), Dr. Masters, Messrs. J. O'Brien, H. M. Pollett, H. Ballantyne, T. W. Bond, W. B. Latham, H. Williams, E. Hill, J. T. Gabriel, Thomas Statter, G. R. Le Doux, E. Moon, W. H. White, J. Douglas, T. B. Haywood, S. Courtauld, and F. Sander.

Messrs. B. S. Williams & Son, Upper Holloway, staged a large, tastefully arranged group of Orchids, including some choice *Odontoglossums*, *Cœlogynes*, *Dendrobiums*, and *Cypripediums*; conspicuous amongst these were *Cypripedium Williamsi*, *C. Boxalli marginatum*, *Lycaste costata*, and some good forms of *Odontoglossum Alexandræ* (silver Banksian medal). Messrs. F. Sander & Co., St. Albans, also sent an interesting collection of choice Orchids. Among these *Phalanopsis Stuartiana*, St. Albans variety, was most noticeable; other good things being *P. Sanderiana*, *Odontoglossum Sanderiana* (very pretty), *O. hystrix*, *Cypripedium Dauthieri* (a yellow variety of *C. Harrisianum*), *C. Wallissi*, and *Phaius amabilis* (silver Banksian medal). A small collection also came from Messrs. Hugh Low & Co., Upper Clapton, amongst others being *Cypripedium callosum* Low's var., a very fine form.

T. Statter, Esq., Stand Hall, Manchester (gardener, Mr. R. Johnson), staged a well grown plant of *Lycaste Skinneri alba* (cultural commendation), bearing ten flowers, as well as some cut Orchid flowers. A few plants of *Phalanopsis amabilis*, Linden's var., were exhibited by Messrs. Linden, Brussels; and a grand spike of *Dendrobium splendissimum* grandiflorum came from W. E. B. Farnham, Esq., Quorndon House, Loughborough. Norman C. Cookson, Esq., Wylam-on-Tyne, exhibited a plant of *Cypripedium hybridum* Bryan (*Philippinense* × *Argus*), a fine form, bearing three flowers on one spike. A plant of *Cattleya Trianae delicata* was shown, this being supplied by C. L. N. Ingram, Esq. W. Furze, Esq., The Roselands, Teddington (gardener, Mr. Coombe), staged a large group of Orchids interspersed with stove plants (silver Flora medal). Several *Cattleyas* came from Messrs. Pitcher & Manda, Hextable. Mr. J. Foster, Berkhamstead, sent some *Cypripediums*, and the most noticeable of them being *C. Elliottianum*. Messrs. J. Laing and Sons, Forest Hill, exhibited Orchids amongst other plants. Some interesting hybrids likewise came from Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea. The latter contribution included *Dendrobium* × *Aeneas*, *Epiphronites* × *Veitchi* (*Epidendrum radicans* × *Sophronitis grandiflora*), and others. Baron Schröder, The Dell, Egham, sent a small plant of *Laelia* × *Viellina*, an exceedingly pretty hybrid, for which a first-class certificate was awarded.

A group of *Odontoglossums* came from W. Thompson, Esq., Walton Range, Stone, and another from C. J. Lucas, Esq., Warnham Court, Horsham (gardener, Mr. Duncan). W. Soper, Esq., Clapham Road, sent a contribution of various Orchids, as also did F. Wigan, Esq., East Sheen, the latter having a grand plant of *Cœlogyne pandurata* (cultural commendation). G. R. Le Doux, East Moulsey, sent a small group, and Messrs. Fred Horsman & Co., Colchester, were adjudged an award of merit for *Lycaste Skinneri* var. *Hettie* (see below). Sir Trevor Lawrence, Bart., Dorking (grower, Mr. W. H. White) sent a charming

group containing *Odontoglossum Ruckerianum splendens* (see awards), *Maxillaria sanguinea*, *Cypripedium Rothschildianum*, and *C. Elliotianum* (silver Banksian medal). A. H. Smee, Esq., The Grange, Carshalton (gardener, Mr. G. W. Cummins), staged three magnificent spikes of *Cyrtopodium Saintlegerianum*.

#### CERTIFICATES AND AWARDS.

*Calogyne Sanderæ* (F. Sander & Co.).—An exceeding pretty species, bearing rather small flowers on an upright spike. The sepals and petals are cream, the fimbriated lip being similar, with a rich orange throat (first-class certificate).

*Lycaste Skinneri* var. *Hettie* (Fred. Horsman & Co.).—A very fine form of *L. Skinneri*, resembling the latter in general appearance, but with a pure white lip and rich carmine throat (award of merit).

*Dendrobium nobile Ballianum* (F. Sander & Co.).—An interesting form of a well known type. The sepals and petals are white with a very faint rose tinge, the lip being also whitish with a rosy purplish tint edged with lemon yellow (first-class certificate).

*Odontoglossum Ruckerianum splendens* (Sir Trevor Lawrence).—The plant shown bore a graceful arching spike containing fourteen flowers. The sepals and petals are rose tinted, densely spotted with chocolate, the lip being similarly marked. The throat is lemon colour (award of merit).

*Maxillaria sanguinea* (Sir T. Lawrence).—A dwarf growing species, the flowers being almost hidden in the grass-like foliage. The blooms are small, of a brownish colour, with a rich crimson lip margined white (award of merit).

*Lælia × Viellina* (Baron Schröder).—A small plant bearing one flower of this exceedingly beautiful Orchid was shown. It is a hybrid of unknown parentage. The flower is self-coloured, the sepals, petals, and lip being of a rich orange shade. A small blotch of crimson is just discernible in the throat (first-class certificate).

*Clivia Scarlet Gem* (B. S. Williams & Son).—This is a splendid variety, with a large truss of flowers borne well above the foliage. The blooms are dark red, with an orange yellow throat (award of merit).

*Caraguata cardinale* (B. S. Williams & Son).—A very fine plant, with green leaves  $1\frac{1}{2}$  inch in width and about 18 inches in length. The flower is a rich cardinal red colour (first-class certificate).

*Chrysanthemum frutescens Alma Brüggmann* (Charles Brüggmann).—A pretty variety of *C. frutescens*, the flowers being of a creamy hue, lemon yellow at the base of the petals (award of merit).

*Begonia Triomphe de Lemoine* (Sir T. Lawrence).—A charming winter flowering Begonia. The flowers are small, but of an attractive rosy pink colour, and borne in great profusion well above the foliage (award of merit).

*Amaryllis Socrates* (James Veitch & Sons).—A splendid variety, with flowers of a bright crimson shade. The plant shown had two scapes, bearing four flowers each (award of merit).

*Amaryllis Eldorado* (J. Veitch & Sons).—The flowers of this variety are large, of perfect symmetry, and rich crimson in colour (award of merit).

*Amaryllis Corinna* (J. Veitch & Sons).—A variety of sterling merit, bearing dark velvety crimson flowers (award of merit).

*Amaryllis Excellent* (J. Veitch & Sons).—Flowers of good symmetry, bright scarlet colour, striped with white (award of merit).

*Amaryllis Nimrod* (J. Veitch & Sons).—This is a magnificent variety with flowers of gigantic proportions. The scape of the plant shown bore four blooms. In colour the flowers are bright crimson (award of merit).

*Corylopsis pauciflora* (J. Veitch & Sons).—This is a hardy shrub from Japan, and the three plants shown were loaded with small yellow flowers (first-class certificate).

*Fritillaria aurea* (T. S. Ware).—The flowers of this comparatively well-known plant are golden spotted with dark brown (award of merit).

*Scopolina Fladnichiana* (G. Paul & Son).—A robust plant, bearing bell-shaped flowers, greenish yellow shade (award of merit).

*Amaryllis Salvator Rosa* (G. Paul & Son).—A distinct variety with rich red with a purple tinge streaked with white (award of merit).

#### THE EFFECT OF COLOURED GLASS ON PLANTS.

AT the afternoon meeting a lecture on the above subject was ably delivered by the Rev. Professor G. Henslow. In opening his subject the lecturer referred at some length to the necessity of light in the germination of seeds. This was still an open question, as experiments conducted by some authorities have been almost directly opposed to each other. It was, however, found that for dark coloured and oily seeds light was really essential; in other cases darkness appeared to be preferable.

The lecturer then referred to some experiments conducted by himself in the use of coloured glass. The colours used were violet, blue, red, green, and yellow. By this means he proved conclusively that it was most injurious to grow hardy plants under any kind of glass. In conducting experiments with seedling Lettuces yellow was found the most satisfactory, and green the worst, but under neither of these were the plants equal to those grown in the open air. After all the experiments which the lecturer has conducted he is still in doubt, and has therefore determined to go through all the trials again, and the result cannot but be interesting when coming from such a source. Violet coloured glass, Mr. Henslow remarked, has been used by a London grower of market flowers, who asserts that by using this colour he can advance his blooms by fourteen days. This, of course, should only be tried on plants grown expressly for their flowers, not on foliage plants, or the effects would doubtless be injurious.

The conclusion arrived at by the lecturer was that for hardy plants no glass at all should be used, either coloured or plain, except of course for purposes of protection against the inclemency of the weather. There could be no question that the light afforded by the sun was the best in every way.

The lecture was rendered more interesting and instructive by the tables which had been drawn up to demonstrate more clearly the results of all the experiments. A vote of thanks was accorded to Professor Henslow for his excellent lecture.

#### SHEFFIELD CHRYSANTHEMUM SOCIETY.

THE adjourned annual meeting of the above Society took place on March 8th at the Museum, Orchard Street, Mr. John Haigh presiding. The question of shortening the long and cumbersome name of "Sheffield, Hallamshire, and West Riding United Chrysanthemum Society" was discussed, and it was unanimously resolved that henceforth the official title of the Society should be "Sheffield Chrysanthemum Society."

At the same meeting there was a strong competition among the exhibits of Cinerarias, some fine plants being shown. Amateurs were allowed to exhibit any plant in bloom, which brought an excellent *Cyclamen* and *Azalea*.

Mr. H. Broomhead, F.R.H.S., gave a most practical and interesting address on "The Approximate Times for Stopping to Procure the Correct Buds." Great interest was evinced in Mr. Broomhead's remarks, which consisted of giving the exact dates of spring stopping which he had found most conducive in bringing about the desired results of having the best blooms at the right time with the varieties he mentioned. He also pointed out peculiarities of growth, as well as the right buds—crown or terminal—to "take" in each case.

Mr. Broomhead being a most successful and enthusiastic grower of Chrysanthemums, intends to give at each monthly meeting brief and seasonable hints on current management for the benefit of the members. His information so freely given at this meeting was highly appreciated by a numerous audience, and he was deservedly thanked for it, as well as for his generous intentions in the future for promoting Chrysanthemum culture. Mr. Haigh was also thanked for presiding.—E. D. S.

#### EARLY-FLOWERING CHRYSANTHEMUMS.

A SHORT note by "Sadoc," in the *Journal of Horticulture*, page 158, alluded to the Madame Desgranges family, white and yellow, as being suitable for borders. But why stop at these, when there are a score of other beautiful varieties, and quite as useful, that can be had in flower from July till November? Their culture is so simple that they are eminently suited for the single-handed gardeners and amateurs who have, perhaps, no greenhouse. Plants can be procured in May, and if immediately planted out in good soil they will soon become established. Of course the more attention given them the better will be the results, but, beyond watering in very dry weather and a little liquid manure when the buds show, they will look after themselves.

The following varieties I have found do splendidly in the west of Scotland:—August—Pompons: Blushing Bride, Early Blush, Mr. Selby (blush); Duchess of Fife, White St. Crouts, and St. Mary (white); Golden Shah, Golden Fleece, Flora (yellow); Fred Pélé (crimson); Maud Pitcher, Piercy's Seedling, and La Luxembourg (bronze hues); Japanese: Madame Desgranges, Mrs. Hawkins, Mrs. Burrell, and Grace Attick (the latter a particularly pretty white). September—Pompons: Madame Leon Lassala, Madame Jollivart, Mrs. Cullingford (white); Précocité (yellow); La Ami Conderchet (primrose); Japanese: P. Radelli, La Perle, Arthur Creepy (white); Madame Toucher de Cariel (perhaps the finest early grown), Madame Leon Collin (bronzy hues); Madame Ernest Bergman, Rose Laing, O. J. Quintus, Mrs. J. R. Pitcher (pink shades); Roi des Précoces, Mons. A. Dufour, and Mons. W. Holmes (crimsoms).

The above contains the best of early flowering varieties, so far as I can judge after annually growing some 4000 plants and buying all the new ones for trial. There are among those of recent introduction some charming varieties, but these I have only grown in pots this season, so cannot say how they will stand the winter in open borders. Perhaps the pick of forty or fifty newer varieties are J. B. Duvoy (pink Pompon), Vicomtesse de Arene (lilac incurved), Reine Chaudon de Brialles (reddish violet); Japanese: Coral Queen, Mons. Dupuis (orange yellow), and, finest of all, Mons. Gustave Grunerwald, a Japanese, pink shade, blooming in August, a gem in every way, but not over-robust.—ANGLO-SCOT.

#### THE NATIONAL CHRYSANTHEMUM SOCIETY AND MR. DEAN.

I MUST insist upon G. Matthew giving his authority for the statement he makes on page 202 of your last issue as follows:—"Why the bitterness with which Mr. Dean pointed out that two provincial growers who were proposed as members of the Committee had taken part in it, and suggested that therefore they ought not to be elected." I give the paragraph my

most unqualified denial. As the name of "G. Matthew" does not appear in the attendance book as present at the annual general meeting, and as there is no member of the Society of that name as representative of an affiliated society it would be interesting to know upon what this second-hand statement is founded.—RICHARD DEAN, *Secretary*.

[Our correspondent, Mr. Matthew, sent his address in due form. There is more "second-hand," also some "first-hand," information in other communications that the Secretary will peruse, and he will be in a position to admit or deny its accuracy.]

#### HOW THE N.C.S. CONDUCT THEIR BUSINESS.

I HAD promised to attend the General Committee meeting of the N.C.S. on the 6th inst., and so that I should not miss any of the business I determined to be in time. I arrived at Anderton's Hotel, Fleet Street, a few minutes before 7.30, and after inquiring of the porter for the N.C.S. Committee-room, I found myself in quite a little crowd going in the same direction. We entered the room and discovered the cabinet ministry of the Society in solemn conclave at the head of the table. Wonderful men for punctuality these committee men are; it was scarcely 7.30, and the large room was nearly full.

It was evident from the genial expressions of welcome extended to us by the Chairman, that something more than the ordinary business had secured such a good attendance of both members and representatives of affiliated societies, and I soon learned that the excitement was to be centred on the first attempt of the Society to carry out their elections by ballot.

The ordinary business was quickly disposed of, and with the exception of one little surprise was a trifle tame. The incident referred to was this: While the Secretary was on his feet addressing the meeting the glass swing doors at the end of the room were suddenly thrown open, and a tall, pleasant-looking man, with a happy smile on his face, entered. I looked in astonishment when I heard someone near me whisper, "It's His Worship, the Mayor," and was somewhat disappointed to find he had come without his chain and robes of office. A thrill of excitement ran round the room, the Secretary put aside his books and papers, and, having selected and smoothed a chair, with solemn deference called upon His Worship to advance to within the sacred precincts of the cabinet there assembled, nods of recognition were passed to one or two favoured members, and the business proceeded.

First came the election of members of the Floral Committee in the place of retiring members, but someone tried to rob us of the very experiment we had come there to enjoy, by moving a resolution that the election be by show of hands as heretofore. But no sooner was this done than a young man in glasses rose to his feet and moved an amendment that the vote be taken by ballot. His few remarks very soon secured for his amendment a large majority, and the business proceeded.

The all-important election of the Floral Committee by ballot was voted by all a success. Now came the election of a Chairman from among that body. Two gentlemen were nominated, and several present took it in turns to testify to the good qualities and capabilities of these two gentlemen until the compliments were exhausted. The N.C.S. seems to be great in compliments, but they cannot go on for ever; and "business" was called by the Chairman.

The ballot system was again brought into requisition, with the result that Mr. C. E. Shea was declared elected. The Chairman announced that the scrutineers had received forty-two voting papers, one was spoiled, twenty-one votes were given to Mr. Shea and twenty to his opponent; the business closed, hats and coats were donned, and general chatter became the order of the day; little knots of members were to be seen gathered in different parts of the room, and, getting hemmed in by the family gathering, I was witness to some very indignant remarks about the election of the Chairman. "Did you get a letter from Mr. Dean?" seemed to be the general question all round, followed by a reply in the affirmative and the production of several letters marked "private," written on paper with the National Chrysanthemum Society's heading, and signed by the Secretary, asking the recipient to come to the meeting and 1, vote for Mr. C. E. Shea as a member of the Floral Committee; 2, Vote for Mr. C. E. Shea as Chairman of the Floral Committee.

Nothing more was to be done, the meeting had broken up, and I am told, according to the general practice, no meeting of the General Committee would be held until late in the autumn. Some of the recipients of these "private" letters from the Secretary had been flattering themselves they were favoured by being in the private confidence of that official, but when it was discovered that this letter had been sent round to several members indignation ran high. Many declared that Mr. Shea had been elected by a trick, and others alleged that a paid Secretary had no right to send round a circular letter to bias a meeting.

I am not well acquainted with the method of conducting business by this Society, but I venture to think (to put it in a mild form) it was extra officious if not unmanly on the part of the Secretary to send these letters against an old and respected member unknown to him, and I noticed particularly the Secretary took care to record his own vote. He may argue, that as a paid officer he has no right to a voice in the proceedings of the Society, but as a member he has a perfect right to influence members. This may or may not be so, but I am inclined to think, with those whose voices I heard at the meeting, that it showed exceeding bad taste, more especially as the circular letters, although they appeared to be marked private, were headed National Chrysanthemum Society, and in some cases the request to record their vote for

Mr. Shea was added by way of a note to the usual printed postcard sent out convening the meeting.—A COUNTRYMAN.

#### THE N.C.S.—"YET THERE IS NO CLIQUISM?"

BEFORE I write on my text will you allow me to answer Mr. Jas. Hamilton, whose letter appears in the last issue of the Journal? Mr. Hamilton informs us that he desires no personalities, and yet he is willing to journey to London and vote me the "very best" medal if I will only publish the letter containing the name of the member I complain of. What is this but a request for a personality? The first article contains a complete charge minus the name. It is the *principle* I attack, not the man, and it is also on behalf of horticulture that Messrs. Pearson, Goodacre, myself, and others take our stand. Very likely the controversy has advertised Beauty of Exmouth, for at present I have more orders than I can execute. But if such be the case, I cannot help it; in fact, have no desire to do so. Now to my text.

Mr. Dean, in the issue for December 1st last, in answer to Mr. Pearson's remarks on "cliquism," says, "But I know of no special Society against which the charge of 'London cliquism' can be more unjustly brought than the N.C.S. Further, I have now been a member of the Committee for some eight years, and I witness plenty of independence in speech and act, but nothing which can be designated 'cliquism.' Let Mr. Pearson get himself appointed as its representative (Notts Horticultural Society) on our Committee and come among us, and become acquainted more fully with our procedure, and I am quite certain that with wider knowledge there will inevitably follow a more enlightened and juster conception of the methods of the National Society."

These are words and very grand ones too, but will the methods and procedure which Mr. Dean seems so proud of correspond? The Wells case is well known and it is settled, but Mr. Dean and the principal officers cannot boast of their part in the settlement. There is, however, one point in this case that no one seems to have specially noticed—viz., not alone did the nameless member base his threat on the fact that his fellow tradesman owed him a small account, but also because some of his varieties were priced lower than those of the member alluded to. But to return to my text, "yet there is no cliquism."

When Mr. Goodacre proposed Mr. Pearson as a member of the Committee, what was Mr. Dean's action? Did it correspond with his letter, a portion of which I have quoted? In my letter of last week I asked why a certain member's name was given such prominence. No one can say why, but a member of the Floral Committee writes me that others did as much as the member Mr. Dean attempts to glorify. When Mr. Addison proposed a rule for the purpose of putting the Society on a sounder basis, Mr. Dean and others objected to it; and I am informed he threatened to resign if the rule was passed. Yet Mr. Harman Payne in a recent letter informs us that, "Even supposing a member of the Society were guilty of the grossest irregularity and proved to be so, there is no rule by which his expulsion could be effected." Then why, may I ask, did not Mr. H. Payne support Mr. Addison in establishing such rule? It was only intended for dishonest members. Those who did their duty in a straightforward and manly way had nothing to fear from it.

The Society has recently adopted a rule by which the Chairman of the Floral Committee must be selected from that body. Two gentlemen were nominated to the position, but the Secretary, I have reason to believe, issued notices prior to the election requesting members to vote for the gentleman who obtained the honoured position by one vote only; and "yet there is no cliquism;" "but if Mr. Pearson will get himself appointed," &c., "and come among us and become acquainted more fully with our procedure, I am certain that with wider knowledge there will inevitably follow a more enlightened and juster conception of the methods of the N.C.S." Really! and does the issuing of these notices account for "plenty of independence of speech and act," which are displayed at the meetings? That all your readers may judge for themselves I attach a copy of the notice hereto.

*Private.*

NATIONAL CHRYSANTHEMUM SOCIETY.

*Ealing, London, W., Feb. 28th, 1893.*

Dear Sir,—I shall be much obliged if you can attend the meeting of the General Committee on Monday next, March 6th. 1, Vote for C. E. Shea, Esq., as a member of the Floral Committee. 2, Vote for C. E. Shea as Chairman of the Floral Committee.—R. DEAN.

Here we have a case of the paid Secretary of a "National" Society doing all he can to influence votes against one of its oldest and most respected members, who, I am informed, never sought the position to which he was nominated, and did not canvas for votes as against Mr. Shea. Would Mr. Dean consider it straightforward and honourable on the part of myself, for instance, to, in a "private" way, attempt to influence members of the Society against himself? I trow not, nor can I believe that Mr. Shea was cognisant of the extraordinary action of the Secretary in his behalf. I am not informed whether the private touting of the Secretary was on the official paper of the N.C.S.; if it was it was an official act and I suspect, wholly unparalleled, whether it is condoned or not. "The servant shall not be above his master," says a grand old book. We shall see if the members of the N.C.S. are content with the action of their servant against one of his masters—a member of the Committee—who, we may fairly presume, would have been elected to the position to which he was nominated had they not been influenced by the Secretary, not in a frank, open, independent

manner, but in what was obviously a private move against Mr. George Gordon; and yet, once more, "there is no cliquism!"—W. J. GODFREY, *Exmouth*.

#### THE N.C.S. ANNUAL MEETING.

A SHORT time since the Floral Committee decided to hold their meetings in private, the reason apparently being that its proceedings were of such a character that, if made public, would add nothing to the credit of the Society. Judging by the report given of the late annual meeting, would it not be well for the Society to consider the advisability of holding all meetings in private? As the Secretary appears to favour "private" methods, he may be expected to fall in with my suggestion for increasing the prestige of the Society. — COUNTRY DELEGATE.

#### SUMMER PRUNING VINES.

I HAVE no desire to criticise Mr. Stephen Castle's practice in Vine culture, as there is no man who grows Grapes better than he does, or who has obtained better results from a commercial point of view. Having seen his work I am in a position to know that the practice of pinching Vines in summer, which he recommends in the *Journal of Horticulture* (page 155), he carries out in the way he describes; but that does not prove that the same method is always the best. Most of us are willing to allow that circumstances alter cases, and this is a case in point.

Mr. Castle plants his Vines rather closer together than most people, so close in fact that he has not room for an extended lateral growth. There is another thing he does with evident benefit to young Vines. They are cut down much lower than most gardeners care to do, according to their strength at the time of planting; but that his practice is sound I have had ocular demonstration. The secret of his success in pinching Vines—if it is any secret—consist in the fact that he does it judiciously, just as one might expect such a skilful grower would do. Mr. Castle's practice, as he explained to me, is not to pinch back the lateral growth until the second or third leaf was well developed. When such is the case we can quite understand that there is sufficient leaf growth left to carry on the functions of the plant, and that the future fruiting buds are secured because of the well-developed leaves being present to foster and sustain them.

While, however, I agree with your correspondent that this close pinching is right enough in some cases, I am equally as certain it is not suitable to all. If the cultivator starts with a weakly Vine, and if he wishes to keep it in that condition, he cannot do better than to follow a persistent course of pinching back the lateral growth; on the other hand, if a weak Vine is to be converted into a strong one in the shortest possible time, it must be allowed to make all the growth possible. This, of course, is a fact well known to experienced gardeners; but I am afraid if this difference regarding the strength of the Vines operated upon is not pointed out, that it might lead to some mistakes.—J. C. CLARKE.

#### BIRDS AND FRUIT BUDS.

CURRENT bushes that had their branches tied closely together and further protected by a few decayed annuals have not a bud touched by the birds. I have for a long time observed that birds do not molest our fruit bushes unless previous to or during rainy weather. December and January were on the whole dry months, and the birds did not interfere with the buds. February, on the other hand, has been stormy, and the bluetits made their appearance, and in a short time did great havoc to some Gooseberry bushes.

Mr. J. Hiam and others do not believe the tits peck buds, but they may have a surprise some day. Dissecting the craws of birds, unless very carefully done, is not a satisfactory way of proving whether they peck buds or not, for they swallow the embryo blossom only, and it being of a friable nature may not be easily discovered; but there is no mistaking they are the depredators. If the bushes are examined immediately the tits leave them, it will be found that the buds are gone from the branches, and with the exception of the pleasing morsel the rest lie like chaff on the ground. As I have witnessed their depredations in about half a dozen counties, coupled with the fact that I have been asked often by different persons if I could suggest some plan to prevent the "zaupets" (their local name) destroying the fruit buds of Plums, Currants, and Gooseberries, I am firmly convinced that the tits do cause injury to fruit buds.—W. T.

#### FLOORS CASTLE GRAPE ROOM.

IF Mr. Barnes (page 203) has not already read the history Mr. McKelvie gives of the Floors Vines on the same page, I have only to refer him to it to make him aware of the fact that I have not to go very "far afield" in search of corroborative evidences to prove "the fact" that Grapes were both well grown and kept before the clever invention of the celebrated Grape room at Floors, about which Mr. Barnes seems desirous to raise some peevish argument as to whom is the most entitled to claim the patent.

On referring to my so-called "briefs," which were published in the *Journal*, I find the first on page 31 of January 12th; the second on page 79 of January 26th. The former is a plain readily understood system of keeping Grapes successfully, while the latter is an undisguised piece of sarcasm not so readily understood.

I am not an employed advocate to any clan, neither do I aspire to be a light to the talented; it remains quite optional to Mr. Barnes to read, much less digest, any note from my pen, and quite unnecessary to repeat any already well known history such as he supposes my short references to Penrhyn to be. But as Mr. Barnes now has opportunities to show his genius, it may be in his power to achieve some high feat beyond our reach, and thus place his patent beyond dispute; yet I hope Mr. Barnes may possess more grace than to charge those who "smile on the plan he adopts" with "idiosyncrasy."—J. H. GOODACRE.

#### PLATYLOBIUM FORMOSUM.

LIKE many other hard-wooded plants, the *Platylobiums* are not grown so extensively as they formerly were, notwithstanding their decorative merits. There, however, are several species well worthy of

FIG. 46.—PLATYLOBIUM FORMOSUM.

the attention of plant growers, and that shown in the illustration (fig. 46) is deserving of universal cultivation.

When well grown *P. formosum* is a most beautiful object, and will thrive well under the conditions generally assigned hard-wood plants. It is a free branching plant, and the stems are slightly hairy. The leaves are dark green above, paler below. The buds are deep crimson, and when expanded the back of the whole flower retains this colour, whilst the front side is rich orange yellow, saving a reniform belt of radiating crimson lines near the bottom of the standard. The flowers are produced during the summer.

#### SCIENTIFIC CRITICISM.

MOST certainly kindly intended, but still apparently incomprehensible, was the criticism passed by the Editor of the "Gardeners' Chronicle" on a couple of remarks in Mr. J. Wright's little *Horticultural Primer*, which was under review. The statement that the stored sap in a cutting is first utilised to form a callus at the base, and from that callus roots are developed, a fact which all who have ever put in cuttings of any

description know to be practically correct, is yet termed scientifically incorrect. It is not the first time in which science and practice have been found out of harmony, and it would in this case seem to be all the worse for the science, or what is termed scientific teaching. Whilst indulging in this piece of destructive criticism, would it not have been better to have gone a little further and found out where it was that scientific theory did not sustain what is always regarded as physiological practice? To have done that would have been constructive criticism. Then, further, it is said that the author of the Primer is not correct in stating that a Crab tree may be changed into an Apple tree by budding or grafting. Scientifically that may be an inexact expression, but practically it is right, and in such a book as is referred to it is a proper expression, because it carries conviction to the unlearned. Of course, in budding, the Crab stem and root remain Crab as long as the stock endures, but the head—and that is the only part of the tree that produces fruit—is just as much an Apple tree as if on its own roots. After all, the public have more regard to simple, practical truths than for scientific refinements.—OBSERVER.

[I have received other letters to the same effect, but it is scarcely worth while to dwell on methods of criticism. The reviewer was, of course, scientifically correct, and had the contexts and explanations been published, with the qualifying terms of sentences, he would perhaps have recognised their influence. In severe excisions for press, the matter retained often suffers in explicitness. The Surrey horticultural lecturers really do know that the stocks of trees retain their characteristics when distinct varieties are established on them, and so explain; they also know enough about propagating to teach the inexperienced how they may succeed and why they may fail. That is the substance of the matter, and the object in view. The lectures are for workers, not scientists. It is a reviewer's duty to point out what he conceives to be errors, and authors should endeavour to profit by wholesome criticism.—J. WRIGHT.]

#### UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE annual general meeting of the members of the United Horticultural Benefit and Provident Society was held at the Caledonian Hotel, Adelphi, W.C., on Monday, March 13th. There was a large attendance, and Mr. G. J. Ingram presided. Having read the minutes for the previous meeting, the Secretary (Mr. W. Collins) proceeded to read the annual report and financial statement, which were ultimately unanimously adopted.

According to the report the Society, we are glad to note, is in a most flourishing condition, which is a matter for congratulation. There has been an accession of fifty members during the past year, and consequently an increase of funds. Three death claims have been paid, and the sum of £88 12s. 8d. distributed to sick members; this being £30 less than during the previous year. The Benefit Fund has a balance upwards of £5486, an increase of £700 accruing last year. From the Benevolent Fund there is also a balance in hand of over £1857, whilst that of the Management Fund amounts to £37 6s. 4½d. The Voluntary Convalescent Fund has a balance of £172 19s. 7d., including £100 from Mr. H. J. and Mrs. Veitch in commemoration of their silver wedding, and to whom the members tender their best thanks. Three members derived benefit during the year from this Fund, which is steadily increasing, there being only a balance of £41 in 1892. The annual dinner was a success, and left a small balance. The Treasurer stated that £1000 had been invested during the past year in Three Per Cent. Stocks, this being the largest sum ever put by in twelve months. The substantial sum of £7700 was now invested in English corporations, the money being laid out as follows:—Nottingham Corporation, £5500 at 3 per cent.; Manchester Corporation, £1200 at 3 per cent.; and West Bromwich, £1000 at 3 per cent.

Mr. G. J. Ingram, in moving the adoption of the report, said that in looking hastily over the rules of the Society that morning it had occurred to him that the advantages derived from being a member of the Society were far before those offered by any other benefit society in the United Kingdom. By becoming a member a gardener was not only making provision in case of sickness, but practically was investing his money in a savings bank. Besides the Benefit Fund there was the Benevolent Fund, which, in his opinion, was a distinct advantage. This enables the Committee to assist distressed members and their widows in deserving cases. In addition to this there was the Convalescent Fund. Looking at all these advantages, the only surprising thing to him was the comparatively few members on the books, and yet the numerical strength is something the Society can be congratulated upon. In 1882 there were 104 members, in 1892, 448, and at present 474. That was a decided increase, but it was not so large as it ought to have been. As to the income in 1882, there were £243 6s. 8d., in 1891 £1037 5s. 6d., and last year £1228 7s. 7d. Of moneys invested in 1882 there were £2485, in 1891 £6700, and, as the Treasurer had stated, at present £7700, thus showing an increase of £1000 invested in one year. If a special effort were made pointing out these facts to gardeners, he thought there would be a still further large accession of members. In his opinion, the only weak link in an otherwise strong chain was the Management Fund. These are days of progress, and if each member were to contribute, say 1s. a year extra the Management Fund might be augmented. Every advantage should be taken to let gardeners know of the existence of the Society. He would conclude by asking those present to obtain new members, and so make the Society

worthy of its name the "United Horticultural." It was a Society they could with confidence recommend to gardeners. (Applause).

The election of the officers for the ensuing year followed at this juncture. The retiring members of the Committee were re-elected, with the exception of Mr. Dickens, who retired. On the proposition of Mr. Hudson, Mr. Hemsley was elected in his place. Mr. W. Collins was unanimously re-elected as Secretary, and a cheque of £28 18s. 6d. was handed him for his services during the year; this amount included £5 for special attention to the Convalescent Fund for the past three years. Mr. Hudson was also re-elected Treasurer. It was stated that eleven new members had been elected that evening, and the Committee were considering the advisability of having an emblem for the Society.

Votes of thanks to Mr. H. J. Veitch and Mrs. Veitch for their generosity in subscribing £100 to the Convalescent Fund, also to the Trustees, Auditors, and the Chairman, were accorded.

#### LIVERPOOL SPRING SHOW.—MARCH 10TH.

THE annual spring Show was held in St. George's Hall on the above date, and although the room was not quite so well filled as in former years, the Exhibition was of a bright and diversified character. Hyacinths and Tulips were excellent, and the Orchids were of remarkable quality, particularly *Odontoglossum Edwardsi*, shown by Mr. J. Jellicoe, gardener to F. H. Gossage, Esq., Camp Hill, Woolton; and *Cypripedium Rothschildianum*, shown, "not for competition," by Mr. J. Edwards, gardener to Henry Tate, Esq., jun., Allerton Beeches. A first-class cultural certificate was awarded for the latter plant.

Messrs. R. P. Ker & Sons, Aigburth Nursery, staged a bank of seedling *Imantophyllums* in 6-inch pots. The forms were decidedly superior to any hitherto seen in Liverpool, fine massive trusses, and flowers of great substance and perfect form being their chief characteristics. A first-class certificate was unanimously awarded. A similar award was made to Messrs. Dicksons, Limited, Chester, for a grand display of Daffodils arranged in sprays and edged with pots of Scillas. Messrs. T. Davies and Co., Wavertree Nursery, exhibited a collection of spring flowering plants, and secured a certificate. Messrs. Fishlock Bros., St. John's Market, were also granted a similar honour for a charming display of wreaths and crosses.

For a group of miscellaneous plants arranged for effect, and occupying about 60 square feet, Mr. J. Jellicoe was first with a pleasing arrangement, having a centre Palm, Crotons at the corners, a groundwork of Maidenhair Fern, from which peeped some charming pots of *Lachenalias*, Orchids, and Daffodils, the edging being of *Panicum variegatum*. Mr. T. Moorhouse, gardener to R. Brocklehurst, Esq., Sandford Park, West Derby, was the other exhibitor. For ten pots of hardy herbaceous bulbous plants, Mr. J. Bounds, gardener to A. L. Jones, Esq., Oaklands, Aigburth, was an easy first. Mr. J. Harrison, gardener to Mrs. W. G. Bateson, Elmhurst, Aigburth, was second; and Mr. T. Hitchman, gardener to Arthur Earle, Esq., J.P., Childwall, third. For six forced hardy plants (*Azalea amoena* excluded) the same exhibitor was first, having a splendidly flowered *Deutzia gracilis* and *Azalea mollis*. Mr. T. Winkworth, gardener to R. Brocklebank, Esq., Childwall Hall, was second. For bouquets, Mr. T. Carling was first in both classes; also in a very strong competition with six pots of Lily of the Valley, wonderfully well flowered.

For eighteen Hyacinths, distinct, Mr. T. Wilson, gardener to O. H. Williams, Esq., Fulwood Park, Aigburth, was first with *La Deul*, Captain Boyton, Lady Palmerston, *La Grandesse*, Marquis of Hartington, *Koh-i-Noor*, *Mont Blanc*, *Obelisque*, Lord Macaulay, Charles Dickens, *Orange Broom*, *Ida*, *Gigantea*, *Schotel*, *Von Schiller*, *King of the Blues*, *Czar Peter*, and *Florence Nightingale*. Mr. W. Peers, gardener to C. E. Terry, Esq., Woolton, was second, and Mr. J. Kelly, gardener to R. Singlehurst, Enfield House, Aigburth, third. Mr. J. V. Thompson, gardener to W. P. Sinclair, Esq., Prince's Road, staged an admirable collection of twelve Hyacinths, securing the first prize; Mr. T. W. Wilson was second. For six Hyacinths, Mr. F. Salisbury, gardener to W. Poulson, Esq., Breeze Hill, Bootle, was first. For the special prizes offered by Messrs. T. Davies & Co., Wavertree Nursery, for six pots Hyacinths, three bulbs in each pot, there was strong competition. Mr. T. Wilson was first, and Mr. H. M. Coates, gardener to J. Smith, Esq., Newstead, Wavertree, second. Mr. T. Hitchman gained the prize for six pots of *Polyanthus Narcissus*.

For twelve pots of single Tulips Mr. W. Kneale, gardener to Major Gaskell, Roseleigh, Woolton, was first, having fine *Keizer Kroon*, *Duchess of Parma*, *Proserpine*, *Ophir d'Or*, red and white *Joost Van Vondel* as his best. Mr. H. Holford, gardener to Chas. McIver, Esq., Beechwood, Heswell, Cheshire, was second; and Mr. J. Kelly third. Mr. Coates was first for six pots of single Tulips, the prize for six pots of double Tulips going to Mr. H. Holford. Mr. J. Jellicoe secured the first prize for six pots of Daffodils.

For two *Amaryllis* Mr. J. J. Craven, gardener to J. G. Grant Morris, Esq., Allerton Priory, staged *Imperial*, a grand dark variety; and *Virgin Queen*, a white flower striped with crimson. Mr. C. Osborne, gardener to H. J. Robinson, Esq., Aymestry Court, Woolton, was second. For six stove and greenhouse plants only Mr. J. Jellicoe exhibited. Mr. T. Moorhouse staged a superb *Clerodendron Balfouri* in bloom, the prize in the corresponding class for a greenhouse plant being taken by Mr. T. Winkworth with a fine *Imantophyllum miniatum*. Mr. Winkworth was also first with two trained *Mignonette*, three *Callas*, and two bunches black Grapes, showing *Black Alicante*.

Three Orchids in flower were shown by Mr. Jellicoe, first; Mr. J.

Bounds, second; Mr. T. Healy, gardener to Colonel Wilson, Hillside, Allerton, third. The prize for one Orchid went to the latter exhibitor for a good plant of *Cattleya Trianae*. He was also successful in classes for one Fern, three Palms, including a magnificent *Cycas revoluta*, and one Palm.

Mr. Moorhouse won in the classes for the most tastefully arranged box of Roses, not to exceed 24 inches by 18 inches, six *Cinerarias*, one hardy *Rhododendron*, and was second in classes for four and one *Azalea mollis*, the first honours going to Mr. J. Harrison with fine specimens. For four hardy *Rhododendrons*, Mr. J. Kelly was first; Mr. Moorhouse being second. The former exhibitor was also placed first for six *Dracenas*, six table plants, and one *Azalea*. For three *Azaleas*, Mr. W. Wilson, gardener to H. Cunningham, Esq., Gorse Cop, Gateacre, was first, and Mr. Jellicoe second. For four *Azaleas*, pots not exceed 8 inches, Mr. C. Osborne was an easy first.

Primulas and Cyclamen have never been shown in such splendid condition, every collection being worthy of a prize. The first honours in each class went to Mr. A. Lewis, gardener to Thos. Neal, Esq., Beechwood, Aigburth. Mr. W. Kneale was commended for a basket of Auriculas.

#### FRUIT FORCING.

**Peaches and Nectarines.**—*Early Houses.*—Thinning the fruits must be proceeded with, regulating the number reserved for swelling off by the strength of the trees and the varieties, always leaving a few more before stoning for meeting casualties during that process or removal after it. Size and quality being the first consideration, one Peach of the varieties that attain the largest size to every square foot of trellis covered with foliage will be found a heavy crop. The varieties that produce fruit of medium size, as *Early Louise*, will be accommodated in a space 10 inches square, and the small, as *Early Beatrice*, swell perfectly when each fruit is given a square of 9 inches. The young shoots having been neatly tied in close to the base, and the superfluous growths removed or pinched back to form spurs on the extension branches, the trees should be allowed to make free growth until they are sufficiently advanced for the general tying down to the trellis. Any shoots that show a tendency to become too strong should have the points pinched out before they have time to disturb the balance of the trees. Growths retained on a level with or above the fruits to attract the sap to them must be kept topped at a joint or two of fresh growths, so as to concentrate it on them. When the weather is bright syringe with tepid soft water twice a day, but in dull weather the syringing must be omitted or done sufficiently early to allow the trees to become fairly dry before night. When syringing is not practised a genial condition of the atmosphere should be secured by damping the floors and borders in the morning and again before night, affording a sprinkling of tepid liquid manure in the evening occasionally. A light mulching of lumpy manure will assist in keeping the borders moist and supply food to the roots. The soil must be kept moist by judicious watering. It is a good plan to turn off the fire heat early on fine mornings, admitting a little air, and increase the ventilation with the advancing temperature. A steady night temperature of 60°, with a rise of 10° to 15° by day, should be maintained until after the fruit is stoned, when the ripening may be hastened if desired by a higher temperature.

*Succession Houses.*—Disbudding must be attended to when the growths are sufficiently advanced. Growths on extensions not required for forming the bearing shoots of next year may be pinched for spurs, and all wood that is not likely to be wanted for the support of the present or the production of the next year's crop of fruit should be cut away. Avoid, however, large reduction of growths at a time, proceeding gradually; and in disbudding commence at the extremities of the trees, and work down to the base. Small or badly placed fruits should be removed as soon as the most promising for the crop can be decided upon, not leaving more to attain the size of marbles than a third of that intended, and only a per-centage of about 25 should be left after they reach the size of pickling Walnuts for meeting casualties in stoning. A temperature of 55° to 60° at night, according to the advanced condition of individual houses, will be sufficient, with 10° to 15° rise by day. Syringe the trees, and supply water as advised for the early houses.

*Later Houses.*—The trees that are to ripen their fruit in August will now be in flower, and should have a day temperature of 50° by artificial means, with 10° to 15° advance from sun heat, and a free circulation of air, the heat falling to 45° at night, with a little ventilation to prevent the deposition of moisture on the blossoms. Where bees visit the houses it is a certain indication of a good set, for these instinctive creatures seldom trouble flowers that do not contain the essential nectar and pollen. When bees do not visit the houses when the trees are in blossom the trellis should be shaken early in the forenoon and again shortly after noon, or the flowers be carefully fertilised with a camel's-hair brush, a feather, or rabbit's tail mounted on a small stick. Late houses should have a free circulation of air with a view to retarding the flowering; but after the blossoms expand they should be kept safe from

frost, a night temperature of 40° to 45° being suitable, the heat being turned on in the morning so as to raise the temperature to 50°, and admit of ventilation. This is imperative, as the fruit does not set well in a confined atmosphere. Inside borders must have the needful supplies of water, not, however, rendering them sodden by needless applications.

**Melons.**—The plants first put out in the ridges or hillocks will now or soon have grown about 2 feet up the roof, and may be pinched if more than one main Vine is required. Train the shoots over the space not less than 1 foot apart; but for early crops it is better to allow the main shoot or stem to extend two-thirds up the trellis before stopping it, which will cause it to push laterals showing fruit freely. The blossoms on these should be carefully fertilised, plucking a staminate flower, removing its corolla, and then brushing its farina on the stigma of the pistillate blossom where it may be left, and at the same time stopping the shoot one joint beyond the inoculated blossom. Earth up young plants as the roots protrude, and transfer those in small pots to larger before they become root-bound, or plant them out before that condition is reached. Successional sowings and plantings must be made according to the requirements of the establishment for a succession of fruit.

Plants growing in hot-water-heated pits over tanks or manure-heated beds for bottom heat, which were stopped at the second rough leaf, have made some laterals, and four of these should be trained over the surface of the bed, stopping them when they have made about 18 inches to 2 feet of growth according to the space. This will result in the production of sub-laterals or bearing shoots. These will generally show fruit blossoms at the second or third joint, and when two or three on a plant are open simultaneously they should be impregnated, stopped at one joint beyond the fruit, after which, with the necessary stopping and thinning of the shoots, the plants may be allowed to fill the allotted space. Fertilisation should be performed on fine days when the pollen is dry, and maintain, as far as practicable, a rather dry atmosphere whilst the plants are in that stage of growth and until the fruit is set.

Keep a sharp look out for predatory pests, as cockroaches and crickets, these being best destroyed by phosphor paste spread on pieces of paper, or laid on pellets on slates, remembering that it is poisonous. Slugs are surest attracted by brewers' grains or bran, or they may be searched for at night with a lantern. Woodlice may be captured wholesale by placing two pieces of old board one on the other, with just sufficient space between them for admitting the woodlice, a little oatmeal sprinkled on the lower board being an attraction, or the Mangold Wurtzel traps figured on page 186, March 2nd, issue of the *Journal of Horticulture*, may be used with great advantage, as these pests do irreparable mischief in a short time when allowed to have their own way.

**Cucumbers.**—Winter-fruiting plants are now making growth freely, and require frequent attention in stopping, thinning, and tying the shoots. All decayed portions of wood and foliage must be removed, also the old wood where practicable to make room for young growth to maintain a succession of fruits, securing the shoots to the trellis, and stopping them one or two joints beyond the show of fruit where there is space, otherwise stop at the fruit. To encourage a free growth of young wood, take off an inch or a little more of the soil from the surface of the bed, and give a dressing of that depth of light turfy loam two parts, and one part of lumpy decomposed manure, and a 9-inch potful of fine charcoal to about three bushels of the mixture. Fresh roots will be freely emitted and push rapidly into the new compost. Then copious supplies of liquid manure in a tepid state may be given as circumstances require, and a sprinkling of the following mixture occasionally on the surface will keep the plants in bearing some time longer—superphosphate, 3 lbs.; powdered saltpetre, 2 lbs.; powdered gypsum, 1 lb.; mix, and apply at the rate of 2 ozs. per square yard.

Add more soil to the hillocks of young plants as the roots protrude through the soil, taking care to have it warm and moderately moist. The night temperature should be maintained at 65° to 70°, and 70° to 75° by day from fire heat, with an advance of 10° to 15° with sun, closing soon after midday so as to run up to 90° to 100°, with abundance of atmospheric moisture. Keep the bottom heat steady at 80°, never less than 70° nor higher than 90°.

#### KITCHEN GARDEN.

**Old Tomato Plants.**—Whether plants recently cleared of fruit shall be any longer reserved, or not, ought to depend upon circumstances. Those in pots may well be thrown away, especially if there are some newly raised plants fit to take their place. If, however, they are fairly clean and have not been recently cleared of young growths some of them would be handy for producing early spring crops. Set them along the front of a low forcing house, give a soaking with liquid manure and a rich loamy top-dressing, more of the latter being added as the roots spread into it, till eventually the pots be quite buried in soil. Thin out the young growths and train irregularly or so as to thinly and quickly cover the roof. Any plants that were previously fruited up the roof may be similarly treated. It is a mistake to starve these old plants, and the least that can be done is to give them an occasional surfacing of artificial manure. Take an early opportunity of cutting off and burning any old insect-infested or diseased leaves. A moderate dry heat and a gentle circulation of air that will be found the best preventives of disease. If the white fly is on the plants paint the hot-water pipes with sulphur mixed with either milk or linseed oil. This should be done before the flowers are opening. In order to be certain of a good set of

fruit go over the plants daily when in flower, and smartly tap all the bunches with a light Hazel stick.

**Newly-raised Tomatoes.**—Plants raised in January should now be growing strongly, and if not already done ought to be potted, placing the plants either singly in the centre of 5-inch pots or in pairs near to the sides of 6-inch pots. Use a light loamy compost well warmed through by means of heated bricks buried in the heap, and clean, lightly drained pots. Select the strongest of the plants, and bury these in the soil well up to the seed leaves, making the soil moderately firm. Keep the plants in a brisk heat, water very sparingly at first, and shade from strong sunshine. Directly they commence to root strongly expose them to the light and sunshine, a shelf near the glass being a good position for them. From the middle to the end of March is quite soon enough to sow seed with a view to obtaining good plants for fruiting, either in cool houses or against open walls.

**Brussels Sprouts.**—If a mild hotbed, covered with either a glazed or rough frame, can be spared for raising plants of these that method is to be preferred. Failing this, sow thinly in either pans or boxes, and place in gentle heat or on a greenhouse shelf to germinate. Seeing that the plants must have a rather long period of growth, they ought not to be planted in succession to early Potatoes, the better plan being to dispose the rows of the latter 42 inches apart, and after they are moulded up plant Brussels Sprouts midway between them.

**Early Broccoli.**—With the last named may well be sown some seed of Veitch's Autumn Protecting, and any other favourite early Broccoli other than Snow's Winter White, May being quite soon enough for sowing the latter variety, the plants being duly pricked out on a sheltered border, and otherwise treated similarly to Brussels Sprouts; these also can eventually be planted between widely disposed rows of short-topped early and second early Potatoes.

**Autumn Cauliflower.**—As a rule all that is necessary is to sow seed of Eclipse and Early Giant with the Brussels Sprouts, and if similarly well treated fine hearts ought to be available towards the end of August. Eclipse may be briefly described as a good early form of Autumn Giant, and if a good breadth of both are planted the supply will most probably hold out till the earliest Broccoli are available. Those who cannot afford space under glass for raising these Cauliflowers should sow on a warm border, protecting the seed and the young plants for a time with strawy litter. The same plan may also be adopted with satisfactory results in the case of Brussels Sprouts and early Broccoli.

**Lettuce.**—Early Paris Market and Golden Queen Cabbage Lettuces are the quickest to attain a serviceable size, and more seed of one or both of them ought to be sown either under glass or on a warm border. Any plants not required for frame culture to be hardened off, and then dibbled out on a warm border, where they should, if possible, be roughly protected for a time. Also sow seed of White Paris or other Cos variety under glass, and a pinch in the open.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### THE EFFECT OF THE WINTER ON BEES.

I AM now receiving information from different sources how bees have wintered. In every case where they have been kept in narrow hives they are all living and healthy. Not so, however, with those of the "combination" type; at least 30 per cent. in them are dead. This speaks volumes for our mode of management. One of the persons I have been in communication with, says—"I mean to try the two queens in the one hive system. I must have been foolish not to have observed your instructions sent with hives for that purpose by you twenty years ago."

#### SEVERAL QUEENS IN A SWARM.

Frequently during the swarming season several queens accompany the swarm, which prevents it settling, when the bees leave and are lost, especially when the apiarist is engaged with one or more swarms. To prevent the loss, immediately the swarm is settled in the new hive put a piece of queen-excluder zinc over the entrance or in lieu of the sliding mouthpiece, letting it remain for two days after hiving.

#### RENEWING COMBS.

It is the usual custom to take the combs of old stocks three weeks after the issue of the first swarm. This is not only a good practice to guard against foul brood, but bees are more healthy and breed better in new combs than old ones, while the honey is always uncontaminated with the bad odour consequent in old combs. That fact, however, is contrary to some of our modern bee-keepers. Still, the practice cannot be carried too far. With a young queen old combs are of little value, because generally the bees build them quicker than the requirements of the queen. It is different with a laying queen of a strong swarm. It is an advantage to have a few combs ready for her to deposit eggs when newly hived; but it must be remembered that I differ entirely from what

"W. B. C." in the "Record" said, that queens were at their best when three months old. Queens are at their best in a few days after mating. For queens to be at their best about October, is what no bee-keeper ever saw or desired.

#### BEST HONEY GATHERERS.

"Ligurian" wishes to know which are the best bees for profit. Those most condemned by scientists have been with us the very best, to wit, crossed Syrians and crossed Punics; in fact the crosses of every imported breed are superior to any pure race. The pure Punics with us have never had a chance, the seasons for several years past being so unpropitious for honey gathering; but as workers they excel all other varieties of a pure race. Carniolans seem to be equally industrious when of the pure breed, and their mildness of temper render veils unnecessary.

Unfortunately these, as well as the Italian Alp bees imported from Italy, are often a mixture of blood with other races, consequently their native properties are unknown to the majority of the present day bee-keepers. Having kept these two breeds—the one for upwards of thirty years, and the other for nearly twenty—it will be observed I speak advisedly. At the time of their importation puffing dealers were unknown in the bee world, and beautiful banded crosses and yellow Carniolans were unheard of until dealerism and journalism became combined.

I have had several questions from correspondents asking for the best bees for some fanciful hive. I have answered them by post to the effect that if the querists are inclined to ignore my advice and use hives of which I do not approve, I would rather they would abide by the interested dealer's advice on management than adopt as mine, and take the consequences.—A LANARKSHIRE BEE KEEPER.

\* \* \* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Insects (M. F.).**—The larger insect you enclose is the too abundant infester of our kitchens, the common cockroach, which is known to take excursions sometimes, and quarter itself in hothouses. It may be captured by a beetle trap baited with beer or syrup, also poisoned by means of phosphorus paste. The smaller and numerous insects belong to the springtail group. It is a species of Tomenturus. They often resort to manure, and run or leap with great rapidity. No doubt they will, if they have the opportunity, eat the soft portions of roots, and also bulbs or tubers. No very effective mode of dealing with them is known. Soot and lime have been recommended as applications, and the insects would be killed by the application of petroleum, suitably diluted, when they can be reached. Possibly a compound of sulphur and soap in the form of a wash would be of use, where the insects injure the crowns or stems of plants.

**Growing Mushrooms (H. O. B.).**—Many persons beside yourself "want to grow Mushrooms," and several have grown them with a manure supply even less than your own. A few days after the bed is spawned it must be cased with soil, and the better the loam is the finer will be the Mushrooms, assuming the spawn runs well. Litter covering is only needed at this season to prevent the soil drying, and this is important. The soil being moist, the litter if used dry, as it may be, will soon be a little damp, and it should not remain long enough unmoved to cling closely to the soil. For sweetening the manure spread it out thinly to prevent over-heating and the necessity for turning "every other day or two." A little mouldiness will do no harm. Spread at once in thin layers in the bed, then when rather dry pressed down, has in many cases answered admirably. Good crops of Mushrooms have been obtained when the manure has been mixed with moss litter used in stables, excessive wetness being avoided. This is quite as inimical as overdryness of the material. The right condition must be determined by individual judgment, and we do not know that it can be explained more clearly than it is in the work you have—"Mushrooms for the Million."

AN advertisement has been sent to us in which the "new white Grape—Chasselas Napoleon"—is offered for sale by the highly respectable firm of Messrs. W. Cutbush & Son. The whole stock is said to have been acquired from the raiser, Mr. G. Reynolds of Gunnersbury Park Gardens, the statement being made in undoubted good faith.

On page 199 of our issue of the 9th inst., Mr. D. Thomson of Drumlanrig states that he has known a Grape under the same name for thirty years answering exactly to the description conveyed in the advertisement. We are requested to look into the subject on the ground that it is a serious matter to purchase a new Grape that may eventually prove to be an old one. The matter is undoubtedly serious, and the more so if the Grape from which so much is hoped prove disappointing. We propose, therefore, as in duty bound, to tell the vendors and the public something of what we know of the Grape that has been grown for eighty years, and probably much longer, as the Chasselas Napoleon. It is, as its name implies, a French Grape, and one of the finest when seen in the form of full bunches of large berries, which is rare, while full crops of such bunches are rarer still.

The true name of the Grape is "Panse Jaune," which we may add in plain English means "Yellow Belly." Expressive but not elegant this name may be thought, and it is possible that the French preferred the more euphonious alternative Chasselas Napoleon. Under this name the Grape has been long grown, both in France and England, but not very extensively because of drawbacks in two important respects—namely, the Vine being an uncertain (generally a shy) bearer and a bad setter.

The following description of Panse Jaune (Chasselas Napoleon) was taken from a Vine and its fruit in the Chiswick collection thirty years ago :—

When the bunches are well set they are large and handsome, long, tapering, and shouldered. Berries very large, oblong, and like those of Muscat of Alexandria in appearance. Skin tough and membranous, adhering to the flesh, of an amber colour, and covered with a thin grey bloom. Flesh firm, sweet, but not richly flavoured. It is very rarely that this Grape sets its bunches perfectly. The condition in which it is usually met with is very few bunches on the Vine, and these so badly set that there are only a few fully developed berries on each bunch. The leaves die pale brown.

We are able to add, as corroborative evidence of the accuracy of the above description, the testimony of one of the greatest French authorities on Vines. In 1854, Comte Odart published the third edition of his *Ampélographie Universelle*, a report of the Vines grown in French and foreign vineyards. The distinguished author describes the fruit as large, oval, pale amber, vinous, but not rich, and goes on to say that sometimes a Vine produces only one or two fine bunches, and a common feature is to find two or three large berries and the majority the size of hempseed. The Comte further states that he had grown the variety for forty years, and that he had found by experiments that the Vine gave the worst results on its own roots, better returns on the Muscat stock, and better still when grafted on the White Frontignan. He recommends "long pruning" as the best method of securing bunches, but is emphatic in describing it as what we term a "bad setter." We have thus clear evidence that the variety is a very old one, and it is probably one of the oldest of French Grapes.

The question now arises as to whether the "new" variety offered is distinct from the genuine Chasselas Napoleon. The descriptions in the advertisement by different writers agree in the "Chasselas Napoleon," exhibited by Mr. Reynolds in 1891, having large oval Muscat-like berries, but paler, and of refreshing (not Muscat) flavour. Those characteristics clearly pertain to this Grape, but the Gunnersbury bunches were described as large and compact, and it is stated in one paper that the bunch was cut from a Vine worked upon a Muscat.

Now, it is of course possible that Mr. Reynolds may have raised the variety from seed at some time and somewhere, then established it on the Muscat, and it is possible that a new seedling may be similar to an ancient variety; but the public is entitled to have definite information on the point, also to know why an English gardener should give a French name to his seedling, and especially when the description of the fruit agrees so exactly with that of the long established French Chasselas Napoleon that was, as we have said, grown and fruited at Chiswick thirty years ago?

It is of course true that the Vines offered for sale were obtained from the "raiser" of them. He would naturally raise them from eyes, but we are without clear evidence respecting the origin of the Vine from which the fruit of Chasselas Napoleon was cut that was exhibited in a collection at the meeting of the Royal Horticultural Society on October 27th, 1891, and certificated. Before such an award was made a discussion should have ensued respecting both the distinctness of the Grape as an English seedling and its claim to an old French name.

In connection with this subject of nomenclature we have been asked to explain the meaning of the term "Chasselas," and, so far as we know, it is here given for the first time. "Chasselas" is the French name for an eating Grape well known in that country. The French dictionaries do not explain the derivation of the word, but the root of it seems to be in Casale, Chasal, Chazale, Chazalis, and Chastel. The meaning underlying all these is that of castle, manor house, or mansion. The most plausible explanation, therefore, of the word is "lord of the manor's or the castle Grape." Perhaps the original was first cultivated by the monks in the abbeys and priories, and hence extended to the houses of the feudal lords, where only such a garden luxury was likely to be found in these days when most of the country was uncultivated and unenclosed. This derivation is borne out by the German equivalent "Gutedel," which means "the noble estate" or manor.

In all probability the Panse Jaune, subsequently Chasselas Napoleon, is one of the ancient Grapes of France, a variety not commonly grown in vineyards because of its shy bearing and bad setting peculiarities, but was practically, because of its fine appearance, retained in the gardens of the nobles for the purpose of having a fine bunch now and then as something of a novelty on their tables.

In the old days artificial fertilisation was not resorted to, nor was it in the Chiswick trials above referred to, or possibly the few bunches might have been better furnished with large berries, in the same way as those of Alnwick Seedling are improved. In the *Journal of Horticulture* (October 29th, 1891, page 372) it is stated that a first-class certificate was awarded for the Gunnersbury bunch of Chasselas Napoleon, "as it was in extremely fine condition." This was clearly intended to indicate that this was unusual in the old Grape that was in the mind of our reporter, and he made no reference whatever to the bunch exhibited being a new variety. He was evidently under the impression that the bunch was generally understood to represent the old French Grape in exceptionally good form. (The *Gardeners' Chronicle* clearly described the Grape exhibited as a "French variety," October 31st, 1891, page 528). The Committee are entitled to award the high honour of a first-class certificate to old varieties distinct in character and of proved usefulness, but for a Grape seen for the first time in

good condition by the majority of the members it cannot be denied that a cultural commendation, or at the most an award of merit, would be much more appropriate. Very great care indeed should be exercised in awarding a first-class certificate to either a variety of Grape or any other fruit. This award leads to the varieties being purchased at special prices, and after such Vines or trees have occupied valuable space for a long time keen disappointment is experienced if the crops are unsatisfactory, and the reputations of vendors, however genuine their action, are impaired.

As is well known admirably furnished bunches of essentially bad setting varieties of Grapes are occasionally seen, and their condition is suggestive of a new or improved variety. When the Morocco Grape was grown well by the gardener at Horsforth Hall, Leeds, it was regarded as a new variety, and called Horsforth Seedling; also, when the same Grape was similarly well grown by the gardener at Kempsey House, Worcester, it was again regarded as new, and extensively sold as Kempsey Alicante, to the grievous disappointment of numbers of persons when it proved to be the old Morocco, one of the worst setters known, and consequently this otherwise good Grape is rarely seen in vineries. But to return to the Chasselas Napoleon. It is necessary, both in the interests of vendors and purchasers, to say that this French Grape as a rule produces bunches less freely and sets its berries as sparsely as the Morocco; and but for these constitutional drawbacks it would have been more extensively grown both in France and England long ago. Mr. William Thomson of Clovenfords has grown the Chasselas Napoleon, which he, presumably, obtained from a former pupil of his, Mr. H. Knight, who grew it at Pontchartrain, France, and who is now gardener to the King of the Belgians at Laeken. We do not know whether it is in the Clovenforas collection. It is not included by Mr. Barron as worthy of cultivation in his work on the Vine.

We suspect there has been some mistake or misunderstanding in reference to the so-called "new" Chasselas Napoleon. This name cannot be properly given to an English seedling, and it cannot be otherwise than advantageous to Mr. Reynolds to exhibit any seedling Grape that he raises under an English name. If he has free cropping Vines of a variety with berries equal in size and quality to the old French Grape named, and at the same time the berries set as freely as Alicantes, without artificial fertilisation, such a variety will be an acquisition, but the true Chasselas Napoleon is not. In dwelling on this subject that has been brought to our notice we have in view the interests of both the public and vendors of Grapes. Any variety that is distinct and good we shall cordially welcome, but the confusion in nomenclature that we have pointed out cannot be otherwise than disadvantageous to all concerned, and it will be admitted that any mistake or accident that may have occurred cannot be rectified too soon to satisfy the Grape-growing community.

### HARDY FLOWER NOTES.

THE customary furious winds of March and its storms of falling snow and dashing rains seem to take delight in tossing and destroying the sweetest and purest of flowers, and in seeking to render as fleeting as possible the pleasures of the garden. But no storms, however wild—no cold, however intense—can hold for ever in check these flowers, which have now rebelled against their long season of rest, and are now mustering their forces to overcome the tyranny of the month.

The Snowdrop, which was among the first to throw off the thralldom of winter, has now a goodly company of supporters. The Crocus, with its golden or white or purple or lavender cups, in sheltered spots proclaims the freedom of the flowers. The Winter Aconite has long preceded it, and well deserves the lines applied to it by the poet:—

"The Aconite that decks with gold  
Its little merry face."

The Chionodoxas, too, are throwing out their flowers from among their fresh green leaves, while their kindred among the Scillas begin to show their blossoms of purple-blue.

Some of the Saxifrages are also making a brave show. *S. luteo-purpurea* is covered with its flowers of pure and lively yellow; *S. Burseriana* and the major form are still in beauty, and the varieties of *S. oppositifolia* are now forming carpets of colour, here of purple, with the typical species; there of pure white, with *S. o. alba*; and there, again, of bright crimson purple, with *S. o. splendens*. Nor does the Pyrenean species or variety (which it is hard to say), *S. pyrenaica*, want its beauty, for *S. p. superba* is now showing its large, bright, deep-coloured flowers.

Primroses, too, are hastening on, and even now some are in beauty, the yellow varieties harmonising well with the white of the Snowdrop and the blue of *Anemone blanda*, which has opened its blossoms also. Nestling under the shelter of a wall, but overhanging a stone in a graceful way, is a good plant of a light, "true flesh-coloured" variety of *Erica carnea*, which is full of beauty, while the white variety previously spoken of is still in flower. The *Leucoium*, too, or Snowflake, has come to rival and succeed the Snowdrop, and its varieties, with their pure white flowers, spotted with green or with yellow, will give pleasure to those who own them.

The Daffodils are dallying long, and as yet only the dainty little *minimus*, with me always the first to flower, has come into bloom; others, however, are full of buds, and promise a rich season of beauty ere long. *Sisyrinchium grandiflorum*, growing near the base of a partially shaded rockery, is now most beautiful with its grassy leaves and its fine bells of purple, or of the white of the variety album. Why is it that such a name as "Swine's Snout" has been attached to such an exquisite flower? If we cannot thus agree that such a name should be a fitting one for the *Sisyrinchium*, whose Latin name is a puzzle to many, what more can we think of the name of "Sow-bread," as applied to the *Cyclamen*, now decorating the garden with its pretty leaves and beautiful flowers? I fancy even the most zealous advocate of English names for flowers will admit that the choice has not been a happy one. Here we might well adopt the alternative of "Bleeding Nun," another name of the *Cyclamen*. It is at least as good as "Sow-bread," and more euphonious. Distinct in colour from anything else at present in flower is *Bulbocodium vernum*, with its bright purple flowers. Cheap as is this flower, its comparative absence from gardens is a matter of surprise. Those, too, who like variety in foliage as well as in flower would do well to consider the claims of the variegated leaved form, which, when the flowers are passed, will form an object of interest with its striped leaves.

How hard seems the fate of that sturdy flower *Primula cashmeriana*, which from time to time throughout the winter has essayed to rear its globular heads of flowers only to have them blasted by some sharp frost. But it is still undaunted, and now a number of heads are covered with their bright purple flowers densely packed together.

Here and there, too, are clumps and plants of *Hepaticas* of various colours and shades, and it was pleasant to read Mr. H. Dunkin's appreciative notice of these plants in a recent number of the Journal. There are few flowers brighter or more beautiful at present; and, severe as has been the season, some of my plants have rarely been without a flower. A writer has praised *H. angulosa* as an earlier bloomer than the others, but I cannot say that I agree with his remarks. The blooming of *Hepaticas* is very much a matter of position, and here (Dumfries) the varieties of *H. triloba* come into flower rather earlier than do either *H. angulosa* or *H. angulosa major*. The *Hepaticas* have not yet recovered from the many years of neglect they have received from the flower-loving public, and it is somewhat tantalising to read some of our old gardening works and have to lament that many varieties are not now to be had. In a few years, however, this will be largely altered; and while on one hand we have lost some *Hepaticas*, it must always be remembered that others are in cultivation of which our ancestors knew nothing. I have at present several varieties under observation, and much interesting correspondence on the subject of some of these old flowers has brought to my knowledge other varieties of which I hope to speak at some future time.

Another flower to which I may briefly refer as at present in flower is *Soldanella alpina*. Very beautiful this is, with its thick round green leaves and pendent bell-shaped purple flowers, beautifully fringed. No choicer plant for the rockery can well be conceived, so neat is it with its compact habit. It has, however, a fault, and that is it is difficult to flower in many gardens. I have struggled with it for some years, and after many failures have at last succeeded by adopting a recommendation given, I think, by Rev. H. Ewbank in a contemporary. This was to cover it in winter with a sheet of glass fixed a few inches above the plant. I covered mine in October, and the glass will be removed at the end of this month. The result is a fine display of flower.

This plant is growing in sandy peat and grit at the base of a rockery, where it receives a good supply of moisture in summer. This *Soldanella* has received the name of the "Blue Moonwort"—a name which shows the inconveniences of some of our "popular" names. When we find the name "Moonwort" applied to a Fern, to *Lunaria biennis* (the Honesty of our gardens), and to this pretty *Soldanella*, it must be admitted that such a system, or want of system, has its inconveniences. A patent example of these is found by the fact that in a series of articles on "Flowers and Flower Lore," which appeared in a London magazine in 1879, the superstition that the Moonwort possessed the wonderful powers of unshoeing horses and opening locks was applied to the Honesty instead of the Fern.

The sight of the beautiful little *Houstonia* coming into flower on the rockery reminds one of how frequently this neat plant is lost from want of knowledge of one simple requirement, which is by no means only recently discovered, having been known more than sixty years ago. This is simple enough, consisting in cutting all the blooms off the plant two or three times in the course of the season. It sometimes requires a little self-denial to do so, but the loss of the flowers for a short time is well repaid by the increase of the plant, while without this precaution it would inevitably perish. *Houstonia coerulea*, which is a native of North America, was introduced in 1785, and was named in honour of Dr. Houston, who resided for several years in the West Indies. It grows to only some 4 or 5 inches in height here, and proves quite hardy on a rockery facing the south in a pocket filled with sandy peat and grit. In the United States it is known by several popular names, among these being "Bluets," which is the one most familiar in Britain. "Innocence," "Dwarf Pink," "Star of Bethlehem," and "Forget-me-not" are likewise applied to it. The typical species can only be called blue by a stretch of the imagination, and is, curiously enough, less plentiful than the white variety, *H. coerulea alba*, which is, however, extremely pretty, and may well be included in a choice collection, covering itself profusely with its small and elegant flowers.—S. ARNOTT.

### OLEANDERS IN SMALL POTS.

THERE are some gardens in which Oleanders are well grown, but there are many others where they present a sorry figure, receiving but scant attention, blooming indifferently, or not at all. Such plants are neither useful nor ornamental, and can furnish but very little pleasure. Oleanders are, to my mind, much more ornamental and useful in small than in large pots. In the latter instance, except under good management, they grow tall and become leafless on the lower portion of their stems, which necessitates their being stood where their bare branches can be hidden by other plants, often to the serious disadvantage of those under notice. Cuttings are so easily rooted that there should be no difficulty in keeping up a stock of young plants. In small pots they would not attain to such length in stem as to make them objectionable and unsightly, and would not be stood in out of the way corners where they have no chance to mature their growths, without which it is useless to expect a full and perfect blossom on plants in large or small pots.

In a Hampshire garden of which I had charge some years since these plants were highly valued, and no difficulty was experienced or trouble spared in obtaining abundance of flowers in their season from plants in pots ranging from 4 inches to 8 inches in diameter. A few cuttings were inserted each autumn, choosing tops that were matured, and furnished with a bloom truss in the extreme point. They are best rooted in a sandy compost, but they answer in wide-necked bottles filled with water, and stood near the pipes in a warm house. In the latter case they ought to be potted as soon as the roots are about an inch in length. When rooted quickly the flower spikes usually develop in the early summer months, and for conservatory decoration such small plants are particularly effective. By the next autumn three lateral shoots will have formed, which if they receive liberal attention in the matter of watering and other details will perfect the same number of flower trusses for a subsequent display. When well rooted they should be transferred from the 4-inch to 6-inch pots, and in these they may be allowed to remain over the second season. In 6-inch pots the plants in our case were so top-heavy with the weight of the flower clusters that they had to be supported with temporary stakes, or by strings attached to the roof-trellis to keep them erect. One more shift were given them—namely, into 8-inch pots, and after doing good service in these they were thrown away, younger ones taking their places.

In some cases young shoots spring up from the base of the original stem, which was taken advantage of in reducing the height

of the plant by cutting it down and giving the sucker growths full play. The flowering tops of the stem cut down furnished the needful supply of cuttings for successional plants without in any way interfering with others retained unpruned. From such practice we were seldom without flowers the whole summer, and instead of being kept rigidly staked the points of the shoots were allowed to assume their natural pendent character brought about by the weight of their own blooms and buds, which on a stage displayed their beauty to the fullest degree.

They were always kept in the greenhouse, this being furnished with roller blinds for giving the requisite shade. They often require water, especially when in small pots, during the summer months. When the pots are full of roots chemical manures may be employed for sprinkling on the surface of the soil.

Turfy loam, enriched with decayed manure and leaf mould, with a sprinkling of dry fish manure added, formed the potting compost. After the pots were filled with roots they were kept standing in saucers of water throughout the summer.—W. STRUGNELL, *Rood Ashton Gardens*.

### DISCUSSION ON PEACHES.

#### ALEXANDER PEACH BUDS DROPPING.

IT is a surprise to me to learn from various sources that Early Alexander is a bad one to force. Our early house is always started at the end of November, and I have never been troubled with buds dropping; the set is also good. I have some trees now well laden with fruit, which is stoning. So highly do I think of this Peach for early work that I would plant no other variety. It is six weeks before Royal George and Darwin Nectarine, and a month before Early York in ripening in the same house. Planted with a house to itself would mean a considerable difference in the coal and labour bill, as a month's firing and labour would be saved, and ripe fruit obtained at the same time as other varieties started a month earlier. We have Early Alexander and Waterloo obtained from two eminent firms about five years ago; but I fail to see any difference between the two, either in wood, flower, foliage, or fruit.—S. T. WRIGHT.

WITH me this variety drops its buds much too freely when growing in a cool Peach house; but out of doors, established at the foot of a south wall, the bud-dropping is unknown. In the open it is a wonderfully free bearer. I took last year five dozen fruits from a tree but two years planted. In spite of this heavy crop of fruit, the growth last season was very free; the promise of a full fruit crop this year is equally good. This Peach appears to be constitutionally weak for growing under glass; but where it is exposed at all times to the open air no trouble is experienced in retaining its flower buds.—E. M.

I HAVE been watching the columns of the *Journal of Horticulture* ever since Mr. Crump first brought the subject up (more than twelve months ago) of the Alexander Peach dropping its buds, for some of your able correspondents to solve the question; but up to the present no one seemed to have given a definite answer. Here I have three trees that have been planted about five years, which drop their buds every year. Two years ago I lifted and root-pruned them, to see if that would make any difference; but no, all the best and most promising buds drop just as they begin to swell. There are a few stray buds left on the terminals and spurs, but not sufficient for half a crop.

I had come to the conclusion that my trees did not get sufficient sun to mature the wood, as the house they are planted in is facing east, so that the sun is gone before midday. As I hear of other gardeners that grow the Alexander Peach under more favourable conditions losing the buds, I have come to a wrong conclusion. In the same house I have sixteen trees of the following varieties:—Hale's Early, Noblesse, Early Beatrice, Princess of Wales, Violette Hâtive, Bellegarde, Barrington, Grosse Mignonne, and Walburton Admirable Peaches; also Pineapple and Elrue Nectarines. None of these drop their buds to any extent, and they all have the same treatment. In my opinion Alexander will have to get different treatment from what other Peaches do before it can be successfully grown.

I greatly favour Mr. Chinnery's idea (page 198), March 9th. Instead of disbudding pinch the growths, so as to form spurs. Perhaps some of your readers have tried the plan already; if so, I hope they will give us their experience.—G. FOSTER, *Glendaragh Gardens, Teignmouth*.

### NOTEWORTHY OBJECTS AT KEW.

#### SARACA INDICA.

THE most striking object in the way of flowering plants in the Palm house is a fine specimen of this leguminous tree about 15 feet in height. Unfortunately this plant can be grown satisfactorily only in large structures on account of the size it attains, otherwise it would no doubt ere this have become a popular inmate of our stoves. The heads of rich orange-coloured flowers are borne on very short peduncles along the stems of the branches. In general appearance they bear a close resemblance to an *Ixora*. The foliage is pinnate, glabrous above and slightly glaucous beneath. This species is a native of India and Java,

and was introduced to cultivation about 1796. It is figured in the "Botanical Magazine," t. 3018, under the name of *Jonesia asoca*.

#### CHRISTMAS ROSES.

Quite the best thing in the grounds during the past month has been a large clump, several yards square, of *Helleborus niger* in the wild garden near the Cumberland Gate. This was planted about two years ago, and has not been disturbed in any way since. This system of naturalisation might with advantage be practised much more extensively, not only in our parks and public gardens, but also in private places. Several of our hardy spring flowers besides *Hellebores* lend themselves readily to such treatment, and many unsightly corners might be beautified by their use.

A large number of named species and varieties of *Hellebores* are grown in the rock garden, and the finer sorts are also utilised to a considerable extent as pot plants for the decoration of the alpine house, which by the way is now beginning to look quite gay and will soon be at its best.

#### BROMELIADS.

Our neighbours on the continent show a keener appreciation of the merits of Bromeliads than we do. It is surprising that these charming plants should gain favour so slowly with us. It cannot be because of difficulties in their cultivation, for no exotics are more easily managed; nor can it be from a lack of beauty in the flowers, for no class of plants, Orchids not excepted, can surpass them in their richness and delicacy of colouring and in the harmonious blending of the various tints of the bracts and flowers. The majority of the plants can scarcely be called decorative, but their deficiencies in this respect are fairly atoned for by their magnificence when in flower.

The collection of Bromeliads at Kew is probably the finest in the kingdom. It occupies nearly the whole of the staging in the Victoria House and one of the stages in the stove, and numbers somewhere about 160 species. At most seasons of the year a fair number of these are in flower. The most noticeable at the present time are *Æchmea cœrulescens*, with small red flowers in an erect panicle; *Æ. glomerata*, flower bracts bright red, flowers reddish lilac; *Billbergia Breautiana*, bright red bracts, deep violet-blue flowers; *B. pyramidalis bicolor*, violet flowers and bright red bracts; *B. thyrsoidea longifolia*, bracts bright red, flowers red with purple tips; *Dyckia frigida*, golden yellow flowers in a panicle about 1 foot long; *Tillandsia microxiphion*, a very dwarf plant, not more than 3 to 4 inches high, with rosy pink bracts and violet flowers. Two plants of *Bromelia fastuosa* are fruiting, bearing huge erect panicles of large, yellow, egg-shaped berries about 1½ inch in length.

#### CALLIANDRA TWEEDIEI.

Although it has been in cultivation for over fifty years, this elegant stove shrub does not appear to be very well known. It is deserving of a greater popularity, for it is handsome alike in foliage and flower. It belongs to the natural order Leguminosæ, tribe Mimosæ, and bears a considerable resemblance to the *Mimosas*. It is of a compact, shrubby habit, and attains a height of about 3 feet. The bi-pinnate leaves, in a young state, are of a delicate light green colour, which is very pleasing and forms a fine contrast to the bright red of the flowers. The latter appear in early spring, and are borne in compact globose heads of about twenty flowers. The beauty of the flower lies entirely in the numerous bristling stamens, with their very long red filaments, and the name, *Calliandra* (beautiful stamen), is very appropriate. It was introduced from South Brazil about 1840, and is figured in the "Botanical Magazine" for 1845. A plant is now flowering in the Palm house.

#### HIBBERTIA DENTATA.

The greenhouse does not present much of attraction in the way of climbers at the present season, but a fine specimen of this *Hibbertia* is worthy of a passing notice. The rich yellow flowers about 2 inches in diameter are freely produced, and show up well against the dark bronzy foliage. *H. dentata* is the best known of the *Hibbertias*, and is worthy of a place in every greenhouse for its foliage alone. It lacks the disagreeable odour which most of the other species possess. It is an old garden plant, having been in cultivation since 1814. A good figure of it is given in the "Botanical Magazine."—A. B.

#### FRUIT PROSPECTS.

NEARLY every fruit tree gives promise of a heavy crop; in fact, our trees here are exceptionally full of bud. Still, it makes us nervous to see the buds coming on so rapidly. Apricots are in full bloom, so are some of the Peaches. Brockworth Park Pear has opened some of its blooms, and other varieties are ready to expand. Plums are ready to burst open, and many Apples are showing the colour of their petals. That grand Apple Lane's Prince Albert is scarcely on the move, and the same may be said of Bramley's Seedling. This lateness is a valuable feature in both varieties, as it makes the crop far more certain.

I commenced spraying on March 7th with Paris green, 1 oz. to 20 gallons of water. On that date I discovered the first larva of the winter moth (which is about three weeks earlier than previous years), and on March 8th I found a female winter moth on the trees. This opens up an important question as to how long the hatching process may go on. Unless I am mistaken the caterpillar plague will be severe this spring, as there are more eggs on fruit trees than usual. *Psylla Mali* will also be strongly to the fore. So far the March moth has not

appeared here. Fruit growers will have to make up their minds to fight insect pests manfully in the west of England if they desire good crops, otherwise the enemy will work serious damage.—S. T. WRIGHT, *Glewston Court Gardens*.

It is most pleasing to note such an abundant promise of a fruit crop. It is not one kind of fruit that gives such a splendid display of flower buds, but all are alike in this neighbourhood. No doubt the comparatively dry weather experienced during August and September of last year is partly accountable for the maturity of the wood and fruit buds. It is generally considered that where Apple trees bear an unusually heavy crop of fruit one year the same trees give promise of but a thin one the following. In our case it is not so this season; trees of many kinds that gave exceptionally heavy crops last year are now literally smothered with buds.

Trees planted but two years, irrespective of variety, give promise of more fruit than will be good for them if we escape the usual spring frosts. Here the flower buds are severely thinned on these recently planted trees. I find the practice is well worthy of the time spent; it does not take long to remove one half of the flower buds from the trees. I prefer to do this just prior to expansion.

Trees planted last autumn, instead of allowing them to carry fruit during the coming season they would be all the better if the buds were pinched off directly they are large enough to handle. The chances of growth of a superior order will be increased, tending much more toward the future success than crippling the trees by premature cropping.

Peach and Nectarine trees on the open walls I have never seen more promising, many of the former are fully in flower. Gross Mignonne on a southern aspect, and Royal George facing east were the first to open their blooms, even before Alexander and other early kinds growing against a south wall.

Plums of all kinds also show well, and Cherries are no exception. Pears show, by the plump buds and breaking calyx, that they mean to give us plenty of flower. Gooseberry blooms are now (March 16th) fully expanded, and the trees are fairly well clothed with foliage. These are, I fear, much too forward to ensure a full crop.—E. M., *Swanmore*.

#### THE SWANLEY PRIMULAS.

"I HAVE a *Primula* such as you have never seen before. You are an enthusiast about these flowers, come and see it;" thus wrote Mr. Henry Cannell a fortnight ago. An ingenious man is the head of the Home of Flowers. He contrives to arouse curiosity, while leaving no means of gratifying it but a journey to Swanley. This is not what may be termed a florist's *Primula*, but a decorative acquisition. Imagine a plant 18 inches to 2 feet high from the rim of a 5-inch pot, and a foot through, with the true *Primula sinensis* foliage. Recall the flowers of the old *sinensis* if you have seen it, single, about three-quarters of an inch across, and nearly white. Clothe the plants with dense clusters of these flowers, not in single trusses, but japonica-like, whorl above whorl on long brown stems, and you have an idea of *Primula The Lady*, by which name Mr. Cannell gallantly describes his new favourite. For freedom of blooming *obconica* has no place beside it; in loose graceful beauty japonica bears no comparison. It is like a well grown pyramidal *Saxifrage* as we sometimes see that useful plant in parlour windows, but with the difference that it is more flowing—more fleecy so to say, altogether more charming. Does this sound promising? If so it may convey some idea of merits of the new star in the *Primula* firmament, and when it is added that it comes from seed just as freely as a weed, and grows vigorously and healthily, it will perhaps be agreed that the plant is worth thinking about. To compare it with the choice forms is futile. It is of a totally different class, calculated to add brightness to greenhouses, conservatories, and windows by its cheerful profusion and clustering wreaths of blossom.

I should like to add a few words about the *Primulas* proper—the forms of *P. sinensis* which comprise the famous Swanley strain. They are a really grand assortment. What splendid size and substance there is in the flowers, and what perfection of truss, can only be gathered from a visit; but I will say a word or two about some of the best varieties. Kentish Fire is a carmine red, very free flowering. Eynsford Purple is a rich purplish carmine. Pink Queen is a lovely soft pink with a fine truss and pips nearly 2½ inches across. Picotee is a distinct and charming flower, white with pink margin. We are getting Picotee forms of everything; a Rose will be cropping up soon. The more the better, for they are all pleasing variations. Duchess of Fife is a Fern-leaved with a fine truss and pinkish lilac substantial fimbriated flowers 2½ inches in diameter. Future Queen is another Fern-leaved of great beauty. It has a very large, evenly formed truss, pips substantial, fimbriated, and nearly 2½ inches across, pure white. This is one of several magnificent whites. Her Majesty, plain leaved, is nearly as good as Future Queen. White Perfection is another splendid one, having noble heads of beautiful pure white pips. In size, substance, form, and purity it might indeed be styled Perfection, but it is doubtful if it is not eclipsed by another superb variety—Eynsford White, which has recently been raised. It is a little earlier than White Perfection, has a large truss, and immense pips of great solidity, pure white with yellow eye. Cannell's White is another splendid variety. Mary James, clear mauve, is very distinct in colour, and has a good truss. Cannell's Pink is a worthy companion to the White. It has a large truss, pips of great size, and the beautiful colour of a La France Rose. Cannell's Favourite is a rich purplish carmine, and, like Swanley Blue, has other points of

merit. Improvement, crimson, is roteworthy for its good truss, but even more so for its splendid habit. The plants average 15 inches across, and have a most even spread of foliage.

To sum up, the Swanley Primulas are in every respect up to the high standard of the firm. They are not only of the highest quality but are grown in enormous quantities, so that collectively and individually they are equally striking.—VISITOR.

### MILDEW IN VINERIES.

FROM the remarks of "A. D." (page 206) on this subject one would infer that mildew is caused only by the roots being in a bad state. The worst case of mildew in vineries that I ever saw occurred eight years since, owing it was thought to the admission of a supply of air through the front ventilators during the time the Vines were in bloom. The sun was shining daily with considerable power, a cold east wind blowing at the same time, causing quite a draught in the vinery, which was planted mainly with late varieties of Grapes.

By the use of sulphur in the way I indicated on page 206 the disease was checked, and by again painting the stems of the Vines the following year, as well as the hot-water pipes occasionally with sulphur also, the mildew was stamped quite out, and has never been any trouble since, no sign of it being visible. The roots of the Vines have not been interfered with in any way since they were planted fourteen years since, with the exception of adding a thin top-dressing of loam and wood ashes annually.

These facts are, in my opinion, most convincing that the state of the roots has but little, if anything, to do with the attack of mildew with which so many Vines have to contend. Yet "A. D." would have us believe that the main cause is attributable to either deficient root action or that which is too gross.—OBSERVER.

### SPRING BEDDING PROSPECTS.

I FIND that the majority of plants employed for spring bedding have passed through the late trying winter without having received much injury. Although the frosts have not been quite so severe as during the winter of 1891-92, vegetation was without the protection of snow throughout the most severe part of the late winter, and I attribute the present satisfactory condition of the plants to early planting. I have on several occasions proved that it is far better to delay any arrears of planting till March than to complete it in the depth of winter, and have once more been impressed with the soundness of that practice.

Having occasion in December last to remove some Violas, they were planted in a couple of beds a few days after sharp weather set in, and I now find on examining them closely that fully one-third of the plants have succumbed, while among large numbers of others set out early in November I have not noticed a single failure. In dealing with these charming flowers I use a number of two-year-old plants which are planted first, beginning the work at the end of October, then the strongest and best rooted are selected from among the cuttings inserted early in August. Those not strong and well rooted are allowed to remain in the cutting beds (which are in sheltered positions) throughout the winter, and are now being placed in their summer quarters. The soil being in splendid working condition is pressed firmly about the roots, a matter of importance in enabling the plants to withstand the drought of summer.

Our soil being light I find it has a great tendency to shrink from the collars of the plants during the winter; those which were planted in the autumn are therefore looked over now, each plant having the soil pressed firmly around it, and the whole surface of the bed lightly stirred with the hoe. The latter practice cannot be too strongly commended as a means of forwarding all kinds of crops, letting in, as it does, the warmth and sunshine of these spring days, which do so much to incite root action, sweeten and fertilise the soil. If these matters are attended to there are signs of an early and prosperous season for spring bedding plants.—H. DUNKIN.

### DENDROBIUM NOBILE IN SMALL POTS.

THE specimens of the above useful Orchid, brought under notice by Mr. W. Oliver on page 220, are certainly excellent examples of cultivation considering the size of the pots. I cannot boast of anything so good in that specified size, but a note respecting some cultivated here will perhaps be of interest.

Two plants of *D. nobile* in 8 and 8½-inch pots, just finished flowering, have carried respectively 365 and 400 blooms each, all well developed. They have not been disturbed for the last six years. I simply pack them with good peat and charcoal amongst the roots as often as required. I might say they are almost living

on the top of the pots, having a network of roots. As long as they continue to thrive so well I shall certainly leave them alone. They teach a valuable lesson in their cultivation.

Of larger plants, a specimen here in one 12 inches in diameter, is now carrying 620 flowers. Another in a pot 14 inches in diameter has 730 blooms expanding. A larger specimen than the preceding, now showing for bloom, promises to be of the same excellence as the others. The plants are grown in an ordinary stove, then transferred to one of the vineries to ripen along with the Vines. My opinion regarding *D. nobile* is it should be grown fast, not unduly shaded, and have a decided period of rest. One objection against small pots is the plants are difficult to stake without lacerating the roots.—J. J. CRAVEN, *Allerton Priory Gardens, Liverpool.*

### TRICHOGLOTTIS COCHLEARIS.

THIS pretty little Orchid does not seem to be very generally known, judging by its rare appearance, even in large collections. The plant is dwarf in habit, and as shown in the woodcut (fig. 47),

FIG. 47.—TRICHOGLOTTIS COCHLEARIS.

has thick slightly channelled leaves arranged in Vanda-like manner on opposite sides of the stem. The flowers are borne three or four together in small racemes springing from the axils of the upper leaves, and are remarkably pretty. The sepals are lanceolate; the petals are broader and rounder at the upper part, both being pure white barred with bright purple—a charming contrast. The lip is curiously hollowed or scoop-like, terminating beneath in a short conical spur, and the form being somewhat suggestive of a shell has given rise to the specific name adopted. *Trichoglottis cochlearis* is a native of Sumatra, whence it was introduced by Messrs. J. Veitch & Sons a few years ago.

### PHALLO-CALANTHE × SEDENIANA ROSEA.

PHALLO-CALANTHE × *Sedeniana* was raised in the establishment of Messrs. James Veitch & Sons of Chelsea from *Phaius grandifolius* fertilised with the pollen of *Calanthe* × *Veitchi*. It is a beautiful thing with flowers of a shade of pale primrose yellow. It is interesting to note that the reverse hybrid has now been raised by Mr. W. Lambert, gardener to John Riley, Esq., J.P., of Hapton House, near Burnley. In this case, says "The Orchid Review," the hybrid *Calanthe* × *Veitchi* was the seed parent, the pollen being derived from *Phaius grandifolius*. It differs from the original form, however, in having the lip light rose colour, marbled with a somewhat deeper shade, and in having a rosy-red line down the centre of each petal. It may therefore bear the name above

given, in order to distinguish it from the original form. Like the type, it is an evergreen plant, and as the spike bore twelve flowers it is a decidedly promising acquisition. It was raised four years ago, and flowered for the first time in January last.

**DENDROBIUM × CHLOROSTELE VAR. OWENIANUM.**

This handsome hybrid was raised in the collection of Norman C. Cookson, Esq., of Oakwood, Wylam-on-Tyne, by Mr. Murray, from *D. Linawianum* crossed with the pollen of *D. Wardianum giganteum*. It is a robust plant with pseudo-bulbs about 3 feet long. The flowers are smaller than those of the pollen parent, but with the same general shape. The sepals are light blush-pink below, passing into rose-purple near the tips. The petals are similar above, but the lower half of each is nearly white. The disc of the lip bears a medium-sized maroon blotch, surrounded by an orange-yellow zone, then a nearly white area; and, finally, a rose-purple tip. The pedicels are  $2\frac{1}{4}$  inches long; hence it is likely to prove useful for cutting. It flowered for the first time in 1891. Messrs. F. Sander & Co. of St. Albans have now acquired a stock of it, and on February 14th last were awarded a first-class certificate for it by the Royal Horticultural Society, under the name of *D. × Owenianum*, but it seems preferable to regard it as a variety of *D. × chlorostele*, *Rehb. f.*, raised in the collection of Sir Trevor Lawrence from the same parentage. Our novelty was dedicated to J. Dyson Owen, Esq., of Selwood, near Rotherham, Yorks.—(*The Orchid Review*.)

**EVENTS OF THE WEEK.**—As announced in another paragraph, the Committees of the Royal Horticultural Society will meet at the Drill Hall, James Street, S.W., on Tuesday, March 28th. On the afternoon of the same day a general meeting of the British Fruit Growers' Association will be held at the Hotel Windsor, Victoria Street, to which all members are invited. A Show of spring flowering plants will be held at the Crystal Palace on Saturday, March 25th.

— **THE WEATHER IN LONDON.**—Dry weather has again characterised the past week, although at times cold winds prevailed. Sunday was warm, but with local fogs, similar weather occurring on Monday and Tuesday. Wednesday opened rather damp and cold, but at the time of going to press it appears to be clearing. Severe frosts have been prevalent, as much as  $10^{\circ}$  and  $12^{\circ}$  being general.

— **WEATHER IN THE NORTH.**—The high winds and showers of the 14th and 15th have been followed by calmer weather. Heavy snow-falls occurred on Thursday and Friday, with frosts of  $5^{\circ}$  and  $6^{\circ}$ . Saturday was bright and fine for the season, the thermometer showing  $9^{\circ}$  of frost in the morning. During the night we had  $12^{\circ}$  of frost, followed by a milder and pleasant day; and Monday was extremely fine, bright, and mild. This morning (21st) the ground is white with hoar frost, and  $5^{\circ}$  frost are recorded.—B. D., *S. Perthshire*.

— **GARDENERS' ROYAL BENEVOLENT INSTITUTION.—ACTS OF KINDNESS.**—Mr. G. J. Ingram, Secretary of this excellent charity, writes as follows:—"Will you kindly give publicity in your widely read journal to the following communication, which I have received from a gentleman who has long been a subscriber to the Institution: 'Sincerely sympathising with the cases of John Butler and Jane E. Nichols, who have been unsuccessful candidates for the pension of the Institution at the last five annual elections, it is my intention to place at the disposal of the Committee, and I hand you a cheque for £36 herewith, the amounts necessary to provide for the present year the allowances to which they would respectively have been entitled had they been elected in January last; at the same time I earnestly hope that special efforts will be made to secure their election on the next occasion.' I need hardly say how gratefully this anonymous gift has been received, nor how glad the hearts of the two candidates mentioned have been made by the good news that I have conveyed to them. Will you also allow me to say that another gentleman, who desires his name to be withheld, has handed me £5 5s. for an exceptional case of suffering and distress which has been recently brought under the notice of the Committee?"

— **ROYAL HORTICULTURAL SOCIETY.**—The next display of fruit, flowers, and vegetables will take place in the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday, March 28th. The various Committees will, as usual, meet at twelve o'clock; at 3 P.M. Monsieur Henry de Vilmorin, of Paris, will deliver a lecture on the "Flowers of the Riviera," which is sure to prove interesting.

— **TOMATOES AND MUSHROOMS FOR PROFIT.**—Can any of your practical readers inform me if Tomatoes growing under glass for market pays, say in a house 100 feet by 20 feet? How many plants could be planted in such a house to return good produce? I should be glad of particulars of construction. Would Mushroom growing in winter after Tomatoes pay after cost of manure, fuel, and labour, locality about twenty miles from London?—NEMO.

— **DOUBLE ZINNIAS.**—I quite agree with Mr. Molyneux's remarks on page 203 as to the usefulness of Zinnias. A bed of Zinnias with an edging of *Centaurea candidissima* or French Lavender makes a fine display. Last season we had three large beds, which were greatly admired. The seed may be sown in boxes in a vinery. The seedlings can be hardened off gradually. Prefer dull weather for planting out, or shade for a time until they are established. Do not plant out till the end of May or the beginning of June.—G. F., *Trafalgar*.

— **BIBLIOGRAPHY OF THE ROSE.**—A copy of a useful book on Rose bibliography has reached us from the author, Senor D. Mariano Vergaro, Madrid. Its title is "Bibliografia de la Rosa," and it is written in Spanish, but it would not be valueless to British rosarians unacquainted with that tongue, for the original French, German, English, and other titles are given for the different works and periodicals listed. The list of books is given under the names of the authors, which are arranged alphabetically; that of the catalogues in sections reserved to each country.

— **GARDENING APPOINTMENTS.**—Mr. W. Barnes, for twenty-two years at Himley Hall Gardens, and for the last thirteen years as general foreman, has been appointed head gardener to G. H. Claughton, Esq. The Gardens, Priory, Dudley. Mr. J. E. McCleave, late gardener to, R. Heywood Jones, Esq., Badsworth Hall, Pontefract, Yorks, has been appointed head gardener to Sir Robert Afflick, Bart., Dalham Hall, Newmarket, Suffolk. Mr. F. Hereman, for the past three years foreman to Mr. W. Lane, King's Ride, Ascot, has been appointed gardener to the Lady Isabella Keen, Rose Mount, Sunninghill, Ascot.

— **ARE WEED KILLERS DANGEROUS?**—In reply to "T. W.," page 72, a good weed killer, in my opinion, is one of the gardener's great friends, but at the same time it is a bad master. It should be carefully used; it should never be employed in gardens where the water from the paths has an opportunity to drain into the tanks. I remember one instance where a weed killer was used on a drive in a large park without sufficient care, where it was allowed to touch the grass edges. Being of a salty nature cattle ate the scorched grass, and two of them died, and several more were in a dangerous condition for some time afterwards.—G. F.

— **SCOTCH FIR.**—The present is a favourable time for planting evergreen Firs in a small state. I find that the Scotch Fir is not only a really good nurse tree in any situation, but grows exceedingly fast. For planting in low-lying places this Pine is valuable, as being late in commencing to make its growth in the spring there is not nearly so much danger of injury from frost as in the case of Spruce Fir, for instance. The glaucous tint which Scotch Firs carry is particularly interesting to some, and on that account this tree is deserving of extended planting in much-frequented sites. Some persons predict a great future for this tree. In years to come when Baltic timber becomes exhausted Scotch Fir will be valuable.—E. M.

— **SUNSHINE AT REGENT'S PARK.**—At a recent meeting of the Royal Botanic Society, Mr. George W. Bell in the chair, the Secretary said the bright weather which characterised the early part of March was much appreciated by plant life, and had brought out the early flowers in the garden and conservatory in a remarkable degree. It had led him to examine the records of bright sunshine made in the Gardens. He found that for the last few years there had been a steady improvement. Last year the total, 1214 hours, was considerably in advance of any of the five previous years, that of 1888 being only 898 hours, and the average of the five years 1037 hours. On Friday, March 10th,  $8\frac{1}{2}$  hours were recorded, a most remarkable amount of sunshine for London at this time of year.

— **BRITISH FRUIT GROWERS' ASSOCIATION.**—A general meeting of this Association will be held at the Hotel Windsor on Wednesday, March 28th, at 2.30 P.M. It is hoped that as many members as possible will attend.

— **DEATH OF MONS. JEAN-EUGÈNE CHAURÉ.**—We have received a notification of the death of this gentleman, who was chief editor of the *Moniteur de l'Horticulture*. M. Chauré died on the 1st inst. at Parc Saint-Maur (Seine), France, at the age of seventy-two, and his loss is mourned by many friends.

— **FLOWERS IN THE SCILLY ISLES.**—According to Mr. T. Dorrien-Smith the flower industry in the Scilly Isles was anything but remunerative twelve years ago. Last year, however, 330 tons were sent away for sale, and this year Mr. Dorrien-Smith estimates the quantity will reach quite 400 tons. During the month of February 182 tons were despatched.

— **EXTREME WEATHER IN WILTS.**—On the 18th inst. cold piercing north-east winds were followed with a sharp frost, the thermometer falling to 21°. The 19th inst. was fine with less wind, the thermometer rising to 62° outside. Apricots, Peaches, and Nectarines are now opening their blooms freely, but the fine dry weather so far is greatly in their favour for the outside trees.—G. F., *Trafalgar*.

— **THE VALUE OF TOADS.**—Our respected transatlantic contemporary, the *Garden and Forest*, says: "In England toads are valued as destroyers of insects, and are offered for sale for 1s. apiece, it is said, in the London markets, being bought by market gardeners." It is questionable whether any market gardener in this country would give 1s. for a toad. If such were the case a new industry would quickly arise.

— **CYTISUS SCOPARIUS ANDREANUS.**—This is a very distinct and beautiful plant, and lovers of hardy flowering shrubs should not fail to add it to their collections. The upper portion of the flower is a clear canary yellow, the inside petals rich velvety chestnut red with yellow reverse, forming a pleasing and effective contrast; and the upright habit of growth shows the flower to the best advantage. It originated as a sport in a field of wild Broom, and is obtainable from the best nurseries.—H. RICHARDS, *Roche Court*.

— **BOTANY IN AMERICA.**—In no country of Europe, not even in Germany, are the results of scientific research more eagerly seized upon for application to the industries than in the United States. This is especially true as regarded the natural sciences and the industries of agriculture and horticulture. As now reported, the State Governments maintain no fewer than thirty-two botanical stations. Systematic botany and the physiology of plants are studied more or less at all these stations; and at every one of them particular attention is given to the diseases of plants and the disease-causing fungi.

— **SUNNY DEVON.**—Apropos of Mr. J. Moorman's remarks (page 217), the following cutting from a recent issue of the "Western Daily Mercury" might be worthy of insertion in the *Journal*:—"Summer is come—one would think so—at least, at Torquay. The winter has been exceedingly mild, if wet, and beautiful spring weather has been experienced for some weeks. During February there were twenty-two days of bright sunshine out of twenty-eight. This lovely mildness has continued during the present month. Flowers in abundance fill the public gardens. Violets are as common as Daisies in summer. The Torbay Road and Rock Walk is a veritable Garden of Eden, and its floral display reflects much credit on the gardener (Mr. Dyer) and his assistant (Mr. Greek)."—DEVONIAN.

— **FLOWERS AND THEIR RELATION TO INSECTS.**—This was the title of a lecture given by Professor Denny at Sheffield recently. Pollen, it was pointed out, was an essential element in the reproduction of plants, and in order to secure its free distribution Nature had developed all sorts of marvellous contrivances. In some cases wind-borne germs were carried from one country to another. Insects were the principal agents in bringing about cross fertilisation. Bees and flies, flitting hither and thither, carry pollen from flower to flower, and thus secure the most vigorous development in the floral descendants. In order to utilise these little unconscious fertilisers to the best advantage, Dame Nature availed herself in the shape of the most dainty devices of such contrivances as miniature decoys, platforms, springs, trap-doors, levers, and drawbridges. The gay colours and sweet scents of plants, their nectaries and honey glands were simply so many baits to attract insect visitors.

— **CRYSTAL PALACE SUMMER SHOW.**—Her Majesty the Queen having fixed May 10th for opening the Imperial Institute, the dates of Crystal Palace grand summer Flower Show are altered to Thursday and Friday, May 11th and 12th.

— **A GOLD MEDAL HERBARIUM.**—According to the *Chemist and Druggist* Dr. Justus Karl Hasskarl has been awarded a gold medal by the Dutch Government in acknowledgment of the gift of his herbarium to Leyden University. The herbarium consists of over 20,000 botanical specimens, mostly collected by the donor, and arranged by him.

— **A TEA GARDEN AT THE CRYSTAL PALACE.**—A handbook of the arrangements for 1893 has been issued by the Crystal Palace Company, and in addition to the flower shows to be held there, we observe that a model of a Tea garden in Assam has been arranged in a building on the north lawns. Indian Tea plants may there be seen in a healthy state of growth, and the preparation of the Tea is carried on in all its stages of withering, fermenting, rolling, and drying by natives of India. The model has been arranged by Mr. Patrick Macgregor, an old Tea planter of Assam.

— **KINGSTON AND SURBITON GARDENERS' ASSOCIATION.**—The first ordinary meeting of this new Society was held on the 15th, when Mr. T. Cushon, of Norbiton Park Gardens, read a very practical paper on the Amaryllis, for which he received very hearty thanks. Several gentlemen were elected Vice-Presidents, and others became honorary and ordinary members. Mr. Cushon's contribution of several well-flowered Amaryllis was much appreciated. Mr. J. Walker, of Ham, having kindly consented to allow the members to inspect his extensive breadths of Narcissi at an early date, it was agreed to visit Ham about the 10th of April.

— **BECKENHAM HORTICULTURAL SOCIETY.**—The Committee of this flourishing suburban Society having arranged for a course of lectures to the members, the first of the series was given at the Public Hall by Mr. A. Dean of Kingston on Friday evening last. The subject of the lecture was "The Potato." This was treated very exhaustively, dealing with its origin, gradual development, cultivation, exhibition aspects, diseases, and antidotes. The lecture was aided by some very fine samples, illustrating sections and varieties. The Rector of Beckenham presided, and there was a large attendance of members, one of whom exhibited a well-bloomed *Cattleya Trianae*, and some very fine Seakale and Mushrooms. Mr. Dean will lecture on the Tomato on Friday next.

— **ROYAL TREES.**—On Friday last Her Majesty the Queen, also the Empress Frederick, and Princess Beatrice, visited Major the Honourable H. C. Legge at his residence, The Gardens, Fulmer, Slough. After having tea with the Honourable Mrs. Legge each of the Royal personages planted a tree on the new lawn, Mr. W. Mowbray, the gardener, assisting in the work. When the ceremony was over the Major kindly presented the trowel that had been used to his gardener with an appropriate inscription engraved thereon as a memento of the occasion. After serving at Fulmer faithfully and well first the late Earl of Leven and Melville for twenty years, and subsequently the present proprietor for two years, Mr. Mowbray is retiring for a well earned rest, his son, Mr. John Mowbray, who has proved his ability as a gardener, succeeding to the charge.

— **THE BIRMINGHAM GARDENERS' ASSOCIATION.**—At the last meeting of the Association, which was numerously attended, Mr. C. E. Pearson of Chilwell Nurseries, Nottingham, gave a lecture on "The Insect Friends and Foes of the Garden," illustrated by lantern slides, dealing in a very able manner with the history and life economy of each subject from the egg and larval state up to the developed moth, butterfly, or other congener; also the vegetable or animal foods required for their subsistence. Advice was also given as to the modes and antidotes commonly adopted for the extirpation of these pests, not that all of which should be regarded as pests, inasmuch as there are certain species of grubs and insects that prey on each other, thus assisting to preserve a balance in nature, which their extraordinary procreation attribute tend to overbalance. Gardeners were earnestly advised to cultivate an acquaintance with entomology, not only as a means for the readier detection and dealing with injurious insects, but also as an interesting recreation for the mind. Specimens of *Anastatica hierochuntica*, the "Rose of Jericho," were exhibited by Mr. Deans (Messrs. Pope & Sons), also dried specimens were contributed by him of some Resurrection Mosses or Selaginellas, all forming a most interesting exhibit. Mr. Walter Jones also exhibited very fine *Cineraria* blooms.

— **ESSAY ON MANURES.**—I find a mistake in the paragraph on Potatoes (page 213), which I shall be glad if you will rectify. The yield of Potatoes should read three to four bags (of 180 lbs.) per rod (not rood), and the word "rod" should also be used three lines farther down in the same paragraph.—G. A. BISHOP.

— **SCOTTISH HORTICULTURAL ASSOCIATION.**—In giving a lecture on the "Cultivation of Peaches and Nectarines" before this Association recently, Mr. Fairgrieve, Dunkeld, said the particular branch of fruit culture which was the subject of the lecture was as of great importance as any in the field of horticulture. As they were aware, there was an increasing demand on the part of the public for fruit, and it was to be deplored that good sound fruit was not within the reach of all. It was the case that foreign countries could not supply Peaches and Nectarines in good condition, and that being so, it was for home growers to show that that fruit could be produced in this country. It might be asked whether the Peach could be grown out of doors to perfection in Scotland, and to that question his answer was that it could, although in many situations it could not. Mr. Fairgrieve dealt with his subject in a practical manner, discussing the question of situation, drainage, stock, and other aspects of the matter in detail, and giving in each case the results of his experience as a grower.

— **IRIS RETICULATA.**—Coming round to Guildford the other morning by rail I was interested with a few passing remarks from some fellow passengers who were struck with some flowers growing in a border beside the platform at one station. I looked over their shoulders and saw that the flowers were a couple of lovely clumps of this early Iris. Just at the moment an official came by, to whom appeal was made for the name of the flower, when he gravely replied, "*Hiris reticulata*," placing special emphasis on the aspirate. This was exceedingly amusing. But apart from the incident it really was delightful to see such fine clumps of this pretty Iris thus blooming at a railway station, and yet there are thousands of pretentious gardens that does not contain a plant of that or other early bloomers.—A.

— **HORTICULTURAL CLUB.—DISCUSSION ON HOME AND FOREIGN FRUIT.**—The usual monthly dinner and conversazione took place on Tuesday evening, 14th inst., at their rooms, Hotel Windsor. There was a large attendance of members, the chair being occupied by the Rev. W. Wilks, Secretary of the Royal Horticultural Society. Amongst others present were the Revs. F. H. Gall, and F. R. Burnside, Messrs. Geo. Bunyard, Geo. Monro, James Webber, Geo. Paul, Jos. Cheal, J. C. Stogden, Arnold Moss, J. S. Cousens, C. T. Druery, J. Assbee, Peter Kay, Alfred Watkins, J. Walker, and Selfe Leonard. The discussion was on the effects of imported fruit on British fruit-growing, which was opened by Mr. James Webber, followed by Mr. Geo. Monro. Mr. Webber's opinion was that as foreign fruits came in before our English-grown fruits were ready he did not think that in most cases competition was injurious, for that as soon as the English-grown fruits appeared on the market the foreign fruit disappeared. The one fruit in which he thought we must be dependent more or less on foreigners was Pears, of which, however, only five varieties were exported to us—Williams' Bon Chrétien, Duchesse d'Angoulême, Beurré Diel, Glou Morceau, and Easter Beurré, and that several of these were not of first-rate quality, certainly not equal to Doyenné du Comice. The same held good with regard to vegetables—as, for example, Lettuces and Asparagus, which were largely imported early in the season; but as soon as the English producer could put his produce on the market the foreign disappeared. Mr. Monro fully corroborated these statements, and at the same time spoke of the injurious effects of the high price of railway carriage, stating that fruit from the Continent could be carried at a lower rate and for a greater distance than the English grown. An interesting discussion followed, in which most of the members present took part. Amongst other things, it was contended that the English public required to be educated on the subject of fruit, and to be shown that high colour, which is more easily obtained in hotter climates is not a proof of excellence, and that, as far as flavour was concerned, no country in the world can produce better Apples than the British Islands. The fruits of Canada, the States, Tasmania, and California are more brilliant in colouring, but not equal in flavour. The Chairman, in summing up the results of the discussion, remarked that perhaps something might be said on behalf of the railway companies, who had to consider the shareholders as well as the public. He also proposed a cordial vote of thanks to Messrs. Webber and Monro, which was carried with acclamation. All felt that a valuable and interesting discussion had been carried out. Several new members were admitted.

— **HEAVY RAINFALL.**—W. Mabbott, The Gardens, Gwernllwyn House, Dowlais, Glamorganshire, writes:—"I have not noticed a heavier rainfall recorded in the *Journal of Horticulture* than has been experienced here. The week ending February 3rd, the fall was 3.19 inches; the week ending February 10th, 1.42 inch; week ending February 17th, 2.95 inches; week ending February 24th, 1.61 inch; and from February 24th to March 3rd, 2.56 inches. The rainfall during January was 3.80. The total rainfall for 1891 was 63.30, for 1892 was 39.56."

— **ESTATE MANAGEMENT.**—"Cotswold" writes:—"I am grateful that 'A Farmer's Wife' was aroused, and to you for giving her reply on page 211 to the letter in the previous week's issue. It matters very little what a man comes from professionally. If he is capable he is the right man: if he is incapable he is the wrong man. What we want are resident gentry, and no charges allowed on land. Old English pastimes are not to be sneered at. With the legislation likely to come the tenants of farms and small holdings will be placed very much beyond interference, and therefore education is the requirement all round, agricultural and horticultural, not fault-finding with the resident landlord who rides to hounds."

— **THE FRUIT INDUSTRY IN CORNWALL.**—In giving a lecture on fruit culture in Cornwall recently at Kea, Mr. Lawry, C.C., a successful grower, remarked that in his parish they had 700 or 800 people, and they turned out 2000 gross of small fruit baskets per year, besides their own wants. And what was more, they could do it at 2s. 9d. per gross, whereas in London they could not get them under 5s. There was, he said, no knowing what Cornish people could do when they put themselves to work. Girls and boys of the parish made these baskets in the winter, and in the summer picked the fruit; earning for the former 11d. per gross, working five or six hours; and for the latter 2s. and 1s. 6d. a day according to the kind of fruit picked.

— **PARASITISM IN PLANTS.**—At the Museum, Newcastle, recently, Professor G. S. Brady, F.R.S., delivered a lecture on parasitism in plants and animals, this being the fifth of the six popular lectures arranged by the Natural History Society. Dr. Embleton presided, and there was a good attendance. Dealing with the parasites on plants, Professor Brady said a true parasite usually had no green colour about it. It had lost all the green colouring matter of its leaves, and became a brown or pinky flesh colour. Green colouring matter, or chlorophyll, was really the essential, not only of vegetable life, but indirectly also of animal life. Those plants which lost the green colouring matter had become degenerate. They also lost their woody tissue to a large extent.

— **SOME SOCIETIES' AMENITIES.**—The engineer of the N.C.S. we find pouring out a bitter complaint against the action of the National Auricula Society in a contemporary, such as makes Mr. Godfrey's growls at the N.C.S. seem tame and commonplace? What does he charge against the N.A.S.? Why, that an expert is brought up to London, employed to dress and help to set up a particular officer's flowers, and then judge them. "I know 'un, he comes from Sheffield," *vide* a "Pair of Spectacles." How much it seems to depend on which "pair of spectacles" is worn, whether those of the N.A.S. or the N.C.S. The moral of all this is, that those who control these or other societies should avoid in every way the appearance of injustice or partiality. But at present what appears orthodox with the N.C.S. would seem with the N.A.S. to be rank heresy.—DIOGENES.

— **THE WEATHER IN AMERICA.**—In a letter dated March 2nd my old friend, Mr. J. W. Lawrence, Harrisburg, P.A., United States, who was up to twenty years ago for nearly twenty years gardener at Farnham Castle, near Aldershot, says, "We are still floundering on through our long severe winter which has kept us frozen up since the latter part of December; but we have not been much below zero, and have not had a great quantity of snow, but what there has been was badly drifted, and we had to take down panels of fencing and cross some fields to get to town. I see by the newspapers that you have had some of it, but a bad English winter is comfortable compared with ours. The ground is frozen 3½ to 4 feet deep, and the snow-banks will not be gone before April. We are still to the front in Primulas, and could not supply all customers last year with young plants, and we hear of none equal to our strains. Trade in Harrisburg has been bad for a long time, and no one seems to have any money to spend. You must not believe all you hear of the wonderful prosperity of this country, as we see daily reports of wages falling and prices of necessities rising." Mr. Lawrence has kept himself from time to time fully supplied with seeds of the superb varieties of home-grown Primulas.—W. D.

— *SCILLA SIBIRICA*.—What a fine effect this lovely blue-flowered bulbous plant produces throughout the present month! No matter under what conditions it is grown it seems to be able to take care of itself; but, like the majority of plants, it well repays the extra labour involved in giving it good culture. We have large numbers of it in various positions, many clumps being located in places where but little attention can be given to them, while others are growing in beds and mixed borders. In all instances they flower regularly and profusely, but those in the latter position have by far the largest flowers; the annual manuring and constant stirring of the soil doubtless produces this effect. I think this fine plant would become even more popular than it is if the bulbs were planted in large clumps or masses. No idea

grows to perfection, is the beautiful *Merveille de Lyon*. Mr. William Paul's Salamander is another impressive variety which Mr. Smith grows and exhibits with distinguished success.

The Rev. James A. Paton, B.Sc., Minister of the Parish of Inch, who himself buds every autumn 500 of the finest Roses, and has frequently gained first prizes at Edinburgh, where he had to compete with eminent professional floriculturists, is entitled to be accounted an accomplished rosarian. Mr. James Hogarth, forester to the Earl of Stair at Castle Kennedy, is a most successful cultivator of Japanese Lilies; while the Rev. Dr. Barty, Minister of Kirkcolm, excels in the culture of herbaceous flowers.

All of these horticulturists, in virtue of their attainments in one of the most exquisite and elevating regions of activity, are entitled to recognition in the *Journal of Horticulture*.—DAVID R. WILLIAMSON.

FIG. 48.—*CARAGUATA CARDINALE*.

of its great beauty under such conditions can be formed by seeing it only in small clumps or lines. A broad, richly coloured mass of this blue *Scilla*, edged with a band of bright yellow *Crocus*, is a sight to be remembered.—H. DUNKIN.

#### WIGTONSHIRE HORTICULTURISTS.

THE County of Wigtonshire, in the extreme south of Scotland, can boast of several horticulturists of considerable eminence. The Floricultural Essays of Sir Herbert Maxwell, M.P. for this county, in the *Nineteenth Century* and other periodicals, are well known to English readers, and have frequently commanded by their originality the attention and approbation of the London journals. His article on "Gardening," which is one of his finest efforts, has not yet been included in his collected works; but I am assured by the cultured baronet that it will have the privilege ere long of being embodied in a new volume of Essays.

In Wigtonshire we have a very successful and popular rosarian, Mr. Thomas Smith of Stranraer, who has frequently carried off the premier prizes at the leading Scottish Horticultural Shows. His splendid display of 1000 blooms at the great Glasgow International Exhibition was much admired by Her Majesty the Queen. His favourite Rose, which he

#### *CARAGUATA CARDINALE*.

WHEN exhibited at the Drill Hall, on Tuesday, March 14th, by Messrs. B. S. Williams & Son, Victoria and Paradise Nursery, Upper Holloway, the above-mentioned plant created much interest, and was awarded a first class certificate by the Floral Committee of the Royal Horticultural Society. It is a remarkably showy South American Bromeliad, and when well known will doubtless become a favourite plant. The specimen exhibited, and from a sketch of which our illustration (fig. 48), has been prepared, was of a dwarf habit, though very attractive in appearance. The leaves are about 18 inches in length and 1½ inch in width, and deep green. From the centre of these, as depicted in the engraving, arises the dense bracts of a bright scarlet or cardinal colour.

Like most of the bromeliaceous plants, *Caraguata cardinale* requires a stove temperature and similar treatment to that generally accorded *Billbergias* and *Tillandsias*. The plant remains in flower for many months, and it will doubtless prove a valuable acquisition.

## NEW FRENCH ROSES.

(Continued from page 215.)

- 15, *François Menard* (Tesnier).—Crimson red, centre cherry red, passing into velvety crimson. Very large, very full; globular firm stem.
- 16, *Ingegnoli prediletta* (Bernaix).—Light rose, mauve on the outside, peach colour inside. Large, semi-double, and cup-shaped.
- 17, *Joseph Teyssier* (Dubreuil) very pale rose, sometimes red, shading off to chrome yellow at the base; sometimes dark rose and carnation colour.
- 18, *Jules Bourquin* (Chauvry).—Chrome yellow, bordered with light lilac. Very large, very full; bud rounded. One of the Dijon race.
- 19, *Karl Maria Von Weber* (Turque).—Dark carmine, at the base yellow. Half full, long bud, flowering singly; very sweet. A seedling from Lajeune Poezeau and Luciole.
- 20, *Krimhilde* (Drogemeller).—Charming yellow, passing to purple rose, the centre golden coppery yellow.
- 21, *La Caleta* (Priez & Ketten).—White, shaded with rose, the centre yellow, coppery salmon, large and full.
- 22, *Léonie Osterrieth* (Soupert & Notting).—Porcelain white, centre shaded with tender yellow, very full, cup shaped and sweet; a seedling between Sylphide and alba rosea.
- 23, *Leon XIII.* (Soupert & Notting).—White, lightly shaded with straw coloured yellow, centre light ochre, large, full and with long buds; a seedling from Anna Ollivier and Earl of Eldon.
- 24, *Louise Bourbonnand* (Nabonnand).—Light golden rose, base golden, very large, full, upright footstalk, with large buds, flowering singly and very sweet.
- 25, *Madame Albert Patel* (Godard).—White, passing into flesh colour, large, very full, showing early, bud round, and very
- 26, *Madame Frenlon* (Moreau Robert).—White, lightly tinted with rose; large, nearly full, and sweet.
- 27, *Madame Henri Greville* (Tesnier).—Yellow, centre lemon colour, bordered with flesh-coloured salmon rose; large and very full, globular.
- 28, *Madame Jean Bansillon* (Godard).—Straw colour flower shaded to yellowish white; large, full, generally single, long bud.
- 29, *Madame Louis Gaillard* (Liabaud).—White flower, shaded yellow; large, full, and sweet.
- 30, *Madame Louis Lévêque* (Lévêque).—Bright red fleshed with light yellow, shaded salmon and white centre darker; large, full, and globular.
- 31, *Madame Martin Cahusac* (Lévêque).—Coppery rose shaded golden yellow, red at the base of petals; very large, full, and gloular.
- 32, *Madame Ocker Ferenex* (Bernaix).—Pale canary, nearly white, tinted with chrome, outside petals often bordered with rosy carmine; large, full, and pointed bud.
- 33, *Madame Guillaumes* (Bonnaire).—White, silver in the centre, shading to orange yellow; medium or large; very full, globular, and firm erect footstalk.
- 34, *Mai fleuri* (Tesnier).—White, glossy satiny velvet; flower very large, very full, Jasmine scented; long bud, erect footstalk; blooms singly; a cross between Fortune's Yellow and Maréchal (Tea).
- 35, *Maman Cochet* (Cochet).—Carnation rose flushed with clear carmine and mixed with nankeen salmon, very large, full, and sweet; outside petals large, the centre sometimes composed of rosette, or indeed nearly cup shaped; almost always holding itself upright. In fact I hardly think from this description it can be anything but a horribly confused flower.
- 36, *Marguerite Breslier* (Jean Ducher).—Light rose colour mingled with rose peach, inside slightly rose; large, full, and sweet.
- 37, *Pierre Marcadier* (Jean Ducher).—Creamy yellow, inside sometimes coppery, very large and very full; seedling from Comtesse de Nadaillac, to which it bears some likeness.
- 38, *Pilar Domedel* (Pries & Ketton).—Very bright rose marbled with white, pale rose when opening, centre lighted with yellow.
- 39, *Président de Lestrade* (Puyradard).—Flame colour, marbled with rose, and sometimes coppery; large, full, and buds long. A cross between Madame de Watteville and Madame de Tostas.
- 40, *Prince Hussein Kamil Pacha* (Soupert & Notting).—Flower blush silver at base, in the centre ochre yellow, with golden back to petals; large, full, more globular than flat. A cross between Anna Ollivier and Reine de Portugal.
- 41, *Princesse de Monaco* (Dubreuil).—Brilliant creamy yellow, outside flesh-coloured rose, tinted with chamois; large, full, with long bud.
- 42, *Siegfried* (Drogemeller).—Dark salmon, large, and very double, cup shaped; very sweet.
- 43, *Sœur Severin* (Reboul).—Silvery white, centre lightly striped; large and full.
- 44, *Souvenir de Claude Dupont* (Godard).—Dark rose, sometimes shaded, large and full.

45, *Sir de Ludovic Talansé* (Pelletier).—Blush white, centre flesh colour, border of petals canary yellow, very large, bud long, egg-shaped, opening well. Cross between Madame Gallet and Céline Noirey.

46, *Souvenir de Madame A. Henneveu* (Bernaix).—Variable in colour, salmon china rose, veined with carmine, often coppery red with reverse amaranth, full, large, with egg-shaped bud.

47, *Souvenir de Mlle. Victor Caillet* (Bernaix).—Pure white flowers with cream colour, large, full.

48, *Thiron-Montauban* (Puyradard).—Bright red, sometimes dark red, full, and large.—D., Deal.

(To be continued.)

## ROYAL HORTICULTURAL SOCIETY.

MARCH 14TH.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters (in the chair), Mr. Michael, Mr. Blandford, Dr. Scott, Prof. Oliver, Rev. W. Wilks, Prof. Farmer, Dr. Müller, Mr. Wilson, Prof. Ward, and Rev. G. Henslow, Hon. Sec.

*Sargasso Weed*.—Mr. Blandford exhibited a specimen collected off the Azores. He also remarked upon a perfectly successful experiment of bringing fresh green Cocoa Nuts from Jamaica in the refrigerator of a vessel.

*Tipulæ in Soil*.—Dr. Müller exhibited some grubs which were pronounced to be a species of this insect allied to the common *T. oleracca*, or Daddy Long-legs.

*Blue Primulas*.—Mr. Wilson exhibited about fifty varieties of different shades of blue, plum-blue, and bluish-violet Primroses, all being seedlings from the original "Scott Wilson," and grown at Weybridge and Wisley.

*Knotted Oak Branch*.—Dr. Masters exhibited a specimen of this well known peculiarity, the stems being sometimes used for walking sticks. He had referred it to a fungologist, who had detected the presence of the fungus *Dischæna discina*. It was a question, however, to be solved whether this fungus was the cause of the knob-like protrusions or not. It was referred to Prof. H. Marshall Ward for further examination and report.

*Cecidomyia Taxi*.—Prof. Farmer exhibited specimens of Yew sprays affected by this well known parasite, which causes an arrest of the axis and the leaves to form a rosette. The question was raised as to whether the shoot subsequently elongated or not. In Mr. Henslow's garden both male and female Yews are always affected by it, the tufts of leaves and shoots attacked dying every year.

*Injuries to Plants by Certain Substances Present in Coal Smoke*.—Prof. Oliver exhibited several results of his experiments in testing the effects of the ingredients of fog and their allied substances upon plants. A frond of *Pheopteris trichoides*, subjected to the vapour of phenol under a bell-glass, was blackened. White Lilac became of a chocolate brown colour; white Cyclamens, however, being unaffected, though killed. It was remarkable that the alcoholic extract of chlorophyll made from the blackened frond was identically like that of the uninjured green leaf, showing that the chlorophyll was "masked," but not altered in character by the phenol. The effects of pyridine were not so marked, as the Lilac and Cyclamen were only slightly tinted with a pale brown colour. Prof. Oliver had tested these and other plants for tannin, but the distribution of this substance in organs which change colour with or resist phenol and other coal-tar products, was found to be such that no positive conclusions could be drawn.

Professor Oliver also showed the effects of sulphurous acid gas, so prevalent in urban fogs. The above-mentioned white flowers were killed by its action. The spectrum of chlorophyll of leaves subjected to its action showed the usual modifications due to the presence of an acid. It is to be noted that the effects produced were only on living protoplasm, no such results occurring if the protoplasm had been previously killed.

Dr. Scott said that he hoped Prof. Oliver would be able to throw some more light on the falling of almost uninjured leaves, which was perhaps the most remarkable of the effects of fog. In these cases the leaves, when they fall, are alive, and show scarcely any symptoms of poisoning. He thought it possible that the investigation of this phenomenon might help to explain the immediate cause of the normal fall of leaves in autumn, as to which we at present know little more than the anatomical conditions.

Prof. H. Marshall Ward, in commenting upon Prof. Oliver's elaborate report, observed that the author had evidently attacked the problem quite in the right way, by experimenting on plants with the separate ingredients of urban fogs; and that as the report showed, the investigation had raised a number of interesting and very important questions in vegetable physiology. It was, indeed, a matter of surprise to see how much information Prof. Oliver had extracted from his investigations in the short time at his disposal. He trusted that the author would persevere with his experiments, as he would have the hearty sympathy of everyone interested in the subject. Prof. Ward alluded to some old experiments of his own in which he found that in fine, dry, bright, and sunshiny weather plants resisted the effects of sulphurous acid better than in dull seasons, thus correlating in an interesting manner the results of Prof. Oliver, in that in foggy weather sulphurous acid gas was most effective in injuring plants. The result of this action was a plasmolysis and diffusion giving the appearance of "sweating" in the cells. The sulphurous acid in the gaseous condition penetrated the inter-cellular spaces of the tissues, and entered the cells in solution.

Dr. Müller called attention to the statement in the report that, according to Dr. Bailey, the organic matter which forms a large proportion of the greasy deposit left by fog, and which proved so injurious to plants, consisted mainly of some form of pyridine. Now, considering that pyridine is a rather volatile liquid substance, this is a somewhat surprising fact, and the question arises how the pyridine and other similar volatile constituents of smoke become thus fixed and precipitated. He suggested that this probably is brought about by the agency of the particles of solid hydro-carbon and tarry ingredients of the fog, which possess great affinity for these volatile substances and absorb them. It is now well understood that these solid constituents of the smoke, along with the mineral dust suspended in the atmosphere, form the primary cause of the formation of fog.

Dr. Masters exhibited sprays of Holly, Skimmia, and Aucuba covered with sooty deposit of fog, but yet the foliage was apparently healthy. He attributed their capability of resisting the deleterious influences by the great thickness of the cuticle possessed by these plants. He observed that evergreens often possessed in addition two or three rows of palisade cells, and were thus enabled by their structure to offer resistance to injurious vapours. Dr. Masters also observed that plants with an aqueous hypodermal layer, such as was present in certain Orchids, might on that account be better able to resist the injurious effects of fogs. Mr. Henslow added that E. I. Rhododendrons have much tannin, a moderately thick cuticle, and aqueous layers on both sides of their leaves, and as they withstood the fogs well these features might corroborate Dr. Masters' suggestion. Dr. Masters also remarked on the observation of Prof. Oliver that Monocotyledons appeared to be less liable to injury than Dicotyledons. He threw out the suggestion that as so many of the former class have a more or less erect phyllodinous foliage, the fog deposit would be less likely to accumulate upon it than on the more usually horizontal blades of dicotyledonous plants. In addition to this morphological feature was the anatomical structure—viz., there being two palisade layers and the presence of stomata on both sides, &c. Such and other histological differences might prove to account for some of the differences mentioned.

The thanks of the Committee were unanimously tendered to Prof. Oliver for his interesting and valuable report.

#### GRAPES AT FLOORS CASTLE.

I WAS very pleased to see Mr. McKelvie's notes, page 203. He knows the writer very well, who regards him as being both shrewd and competent. That the old Vines under his care still flourish is pleasant to notice, as there is an interest attached to old stagers. I was wrong in my surmise that the photo which you illustrated recently of the Floors' Grapes, but had they been from the original Vines I would not have been surprised, as the case in point reminded me of a photo which was taken of Grapes on the Vines which were forty years old. We know something about Grapes, but a good deal, I fear, we shall never know, more particularly the influence of different soils upon the produce. I have known in different places Muscats do very unkindly, when again with no greater care for a score of years they were never known to fail. The keeping of Grapes after they are ripe is a point well worthy of a little discussion. If they are ripe early in the year—in autumn—and not carefully ventilated, they will soon go or shrivel; then if the temperature is kept too low it will soon cause a state of matters that no care afterwards, however good, can correct. Not long since a first-class salesman showed me some black Grapes, saying, "I don't know what is the matter with these Grapes, but they won't keep." I said I thought the grower had been keeping them too long without fire heat. When Grapes are cut and bottled, it of course alters the case, and they are much easier kept in that way.—M.

IN reference to the controversy on "Grape Keeping at Floors," it is very evident that before a gardener can keep Grapes well he must grow them well. The question is, Who grew the Vines—who took out all the stagnant borders and drained them thoroughly, replanting two houses over again and absolutely restocking the others? As I had a fair share of the work on the borders I can testify as to the practical manner in which the borders were made. Plenty of half-inch bones and Thomson's Vine manure were used, and the Vines are producing what Mr. MacKellar anticipated—good Grapes—whether for keeping or present use. Such are plain facts, and I do not think the imagination of Mr. Goodacre can alter them. Perhaps it may not be out of place for me to ask him to give evidence of his own practical genius on Grape keeping (as he invited Mr. Barnes to produce his) for the benefit of the readers of the *Journal of Horticulture*.—I.

MR. GOODACRE seems ill-pleased to find that anyone should have had the temerity to comment on his remarks on the above subject, which he evidently had been at some trouble to sandwich with his paragraph on keeping Grapes (page 172); but I suppose that anything he writes to the public Press on keeping Grapes, or kindred subjects of gardening, is as amenable to comment as other people's, whether he aspires to be specially talented or not.

I have no inordinate desire to evolve a "patent" or to "adopt" any other person's without due acknowledgment; and much less have I that a discussion on the Grapes at Floors should resolve itself into a mere passage of arms with Mr. Goodacre, for whatever his qualifications

may be to write on Grapes generally, there are others as competent as himself to speak on those at Floors.

My remarks on page 79, which Mr. Goodacre characterises as an "undisguised piece of sarcasm," contain a brief statement on the history of the Grape room at Floors, which was figured on page 31, without in any way raising the question whether Grapes had been successfully kept there before it was made or not; therefore, what Mr. Goodacre's "facts" really went to "prove" does not appear to be very clear.

I should not have troubled to notice his remarks on keeping Grapes (page 172) had he not fallen into the same error as "M." in supposing the Vines were "between thirty and forty years old," and that "all the important work was done for them years ago." Without inquiring what in Mr. Goodacre's opinion is "important work," I may inform him I have read Mr. McKelvie's letter, with the result that I consider it ample proof (if proof was needed) of my statement on the same page, and at the same time sufficient correction for what Mr. Goodacre had rashly assumed to be facts—namely, that there were Vines at Floors between thirty and forty years old. "M." will likewise see from Mr. McKelvie's letter that the early vinery he speaks of on page 117 was planted again during Mr. Knight's time, and the fact of it being found so unsatisfactory when Mr. MacKellar took charge sufficiently accentuates my remarks on the cause of the premature breaking of the Vines being due to the heated border.—N. F. BARNES, *Eaton Gardens*.

#### EURYA LATIFOLIA VARIEGATA.

FOR grouping in large conservatories or cool houses where plants are a distance from the glass and receive very little light, this is one of the best variegated plants that can be grown. It is as effective in these positions as Crotons are in the stove, and I am surprised it is not more generally employed for this purpose. It certainly possesses an advantage over Crotons; it retains its colour in shady places, which Crotons do not.

Not only is this plant useful in pots, but it makes a handsome pyramidal specimen for the conservatory when planted out. Once a plant attains a fair size pruning will do it no harm, and numbers of well-coloured ends can be removed for various decorative purposes. Highly coloured foliage during the winter may be used in many positions with advantage, and prove as effective as flowers. Plants in a young state grows slowly, but once they attain a height of 12 to 18 inches they appear to make much more rapid growth. This plant in a young state needs no stopping, it branches freely, and naturally assumes a pyramidal shape.

Cuttings root freely if inserted in sandy soil and covered with a bell-glass or stood in a close-fitting handlight in a cool house. The shoots selected should be the young growths of the current season's wood. If inserted earlier in the season they may occupy a position outside, only being removed at the approach of frost where they will be safe for the winter. The young plants by spring will be rooted and ready for potting. In the early stages they grow quicker when given intermediate treatment.—W. BARDNEY.

#### ROYAL METEOROLOGICAL SOCIETY.

AT the monthly meeting of this Society, held on the 15th instant, Dr. C. Theodore Williams (President) in the chair, Mr. Shelford Bidwell, F.R.S., delivered a lecture on "Some Meteorological Problems," which was illustrated with numerous photographs and experiments. The lecturer said that one of the oldest and still unsolved problems of meteorology relates to the origin of atmospheric electricity. Many possible sources have been suggested, among them being the evaporation of water and the friction of dust-laden air against the earth's surface. Having granted some sufficient source of electrification, Mr. Bidwell said that it is not difficult to account for the ordinary phenomena of thunderstorms.

Photography has shown that the lightning flash of the artists, formed of a number of perfectly straight lines arranged in a zig-zag, has no resemblance to anything in Nature. The normal or typical flash is like the ordinary spark discharge of an electrical machine; it follows a sinuous course, striking similarly to that of a river as shown upon a map. The several variations from the normal type all have their counterparts in the forms taken by the machine spark under different conditions, and the known properties of these artificial discharges may be assumed to afford some indication as to the nature of the corresponding natural flashes. Thus, for example, the ramified or branched flash, from which no doubt the dreaded "forked lightning" derives its name, is probably one of the most harmless forms of discharge. Ever since the time of Franklin it has been customary to employ lightning rods for the protection of important buildings. According to Dr. Oliver Lodge these are of no use in the case of an "impulsive rush" discharge, which, however, is of comparatively rare occurrence. Lightning conductors, however well constructed, cannot therefore be depended upon to afford perfect immunity from risk.

Mr. Preece is of opinion that the "impulsive rush," though easily producible in the laboratory, never occurs in Nature. Mr. Bidwell made some remarks as to the duration of a lightning flash, and the causes of its proverbial quiver, and suggested an explanation of the characteristic darkness of thunder clouds, and of the large rain drops which fall during a thunder shower. The lecturer concluded with some observations concerning the probable cause of sunset colours, which he attributed to the presence of minute particles of dust in the air.

## FLORAL COMMITTEE OF THE N.C.S.

I HAVE just (March 16th) received your issue of to-day, wherein appear certain letters referring to the late election of Chairman to the Floral Committee of the National Chrysanthemum Society. I can assure your correspondents, anonymous and otherwise, that I have in no way sought the office either of Chairman or member of the Committee in question, nor can I permit my name to be connected with the contests which have during the last two months been occupying your pages.

I had been urged to accept the decision of the General Committee electing me to the office of Chairman on the assurance that, as one entirely unconnected with the late disputes, I might be instrumental in guiding the Committee into less troubled waters than it has enjoyed of late.

It is a fact that the majority was a narrow one, but two names only being before the meeting, it did not occur to me that it would be less proper, or more difficult, for the holder of the majority, however small, to accept the result of the election, than for the gentleman owning a minority of a similar extent. However, I now learn for the first time that a formal canvass was made on my behalf under the circumstances stated by your correspondents, and it is alleged that such canvass placed Mr. Gordon at a disadvantage; the suggestion of course being that the twenty votes recorded for that gentleman were due to no prior effort or understanding, a suggestion which I at once accept.

Without in any way imputing blame to Mr. Dean, who doubtless considered himself fully at liberty to act as a member, as well as Secretary of the Society, I may at once say that I could not, had I been aware of the intention, have authorised such a canvass on my behalf. In saying this I must add that I fully believe that the only object Mr. Dean had in view was to secure a chairman absolutely severed from the unfortunate issues which have lately been raised in connection with the Floral Committee, with reference to which Mr. Dean has neither sought, nor can he know, my views.

In the circumstances, willing as I am to assist the Society by any means within my power, I cannot consent—as I have to-day intimated to the Secretary—to accept either the office of Chairman or member of the Floral Committee under conditions which might, even by the remotest appearance, lead to the suggestion of partisanship, and certainly not at the cost of being drawn into the miserable squabbles into which the “Wells” and “Godfrey” cases have degenerated, and of which, I would venture to suggest, many of your readers are beginning to be somewhat tired.—CHAS. E. SHEA.

[While we have left our correspondents to record their opinions as freely on one side as the other on debateable matters of distinctly public interest, we feel it incumbent in this latest development to say that in our opinion no other step was open to a high-minded gentleman than that taken by Mr. Shea. We do not gather from letters which have been sent to us that Mr. Shea is regarded as other than admirably fitted for the position to which he was elected, but the extra official action taken in a moment of over-zeal on his behalf is strongly objected to. Mr. Shea, as an amateur and country gentleman, had in those respects, coupled with business aptitude and a judicial mind, strong claims to be considered a “fit and proper person” for the position from which he retires, and we are convinced that by no one would his election have been more cordially accepted than by Mr. George Gordon had no private action from an unexpected source been taken against him.

Mr. Gordon, by a long and honourable career in the Chrysanthemum world, has many friends. It is only natural that they should wish to see his services recognised, and hence his nomination for the vacancy which he was so well qualified to fill. Neither he nor Mr. Shea sought the position, but both very properly acquiesced in the desire of a considerable number of members to stand for election, and it could not have entered the mind of either that any private influence on the part of an official could have been brought to bear in favour of one as against the other.

No matter how good the motive that impelled to this action, it was not the less unfortunate, and bound, as might have been foreseen, to lead to “squabbles.” These cannot possibly add dignity to any society, and must eventually affect its prosperity. Causes for dissension should therefore not be created, and on those who create them by errors in judgment must rest the responsibility. We shall be glad if it can be arranged for a chairman of committee to be elected without a contest, and we should much like to see all causes of strife removed.

We did not know that Mr. Gordon was associated with the “unfortunate issues,” nor do we think the best way of ending existing differences is by public references to them. These invite replies, and we know that important members of the N.C.S. feel that the “Godfrey” case has not been frankly dealt with on its merits.]

## NATIONAL CHRYSANTHEMUM SOCIETY.

ALLOW me to tell Mr. Godfrey he misquotes me (page 222), which is surely not his “principle,” and if he refers to what I wrote he will see his mistake, which I need not further refer to; only I may tell him that

someone has sent me three copies of the letter that has often been alluded to, and I do not admire the courage displayed in the case.

Now, Mr. Dean has opened himself by replying to a few of the many who wish to guide him in working the N.C.S., I trust soon to hear he has got all raisers and growers of seedling Chrysanthemums who are on the Floral Committee to retire, as such are out of place there. If say two judges who are not Floral Committeemen, and one or two Floral Committeemen who are not raisers or growers of seedlings, be appointed to adjudicate on seedlings brought to shows, not meetings, then exhibitors would have confidence in the Society and bring their seedlings in such numbers as would make a brave show in themselves, seeing how many growers are now raising new varieties.

I see new Chrysanthemums are exhibited in a cut state. I should say this is wrong, as we want Chrysanthemums dwarfed and with stronger flower stems. If exhibited on plants as well judges could give points to such as have strong flower stems and are dwarfer than are some which we now have.—JAS. HAMILTON, *Byrkley, Burton-on-Trent.*

## JUDGING CUT BLOOMS BY COMPARISON.

COMPARISONS are odious to “Sadoc,” evidently, for at page 180 he condemns this practice with several others. Is not all judging a question of comparisons, and do not the points given mean the measuring of the distance between such? I have tried what “Sadoc” thinks is the proper way of judging, but must own I do not feel quite satisfied with it, and have seen other good judges puzzled at the result of the totals in points. I believe that the nearer you can get two objects together the easier it is to detect the difference between them. We all know what it is to go first to one garden and then another to see who has the best Grapes and flowers, and then how faulty our judgments have been when we see the produce side by side on the exhibition table.

Would “Sadoc,” in judging for the best bloom in any show, be content to give the award to a flower in any stand that had gained the highest number of points, say six? Would he not lift out what he thought the best bloom and carry it round with him to all others that had gained six points, and compare them to see if it should be the premier bloom? If this is the best test for single blooms it must apply to a stand of twelve or twenty-four blooms. To find the best, say of any two stands very near, I would remove the one to the other. This is easily done by bringing a board of twelve blooms and having it held by anyone; then we will start with the left hand flower in the back row, working towards the front, not searching for flowers of the same variety, although the same two varieties will be often found placed in the same places in different stands, such as *Etoile de Lyon* and *Vivian Morel*, for exhibitors know the best places to put the telling flowers. On the same principle of judging for the premier bloom in a show one variety is pitted against the other, so are these flowers taken.

Judges who have been growers have the advantage of knowing what varieties are difficult to produce good form. Stand A and B are then inspected, one flower at a time, and the distance of the one above its rival is noted down in points. If they are considered equal neither scores at the finish, and the two stands should be left together till the next stand of twelve blooms is compared, then before separating them give a point for colour and freshness, which is easily determined when the stands are side by side. I do not say that “Sadoc’s” way is wrong, having tried it with others; but it means trusting to his mind’s eye to carry size, colour of say twenty-four or forty-eight blooms to a distance, and in my opinion the surest method is having the two objects side by side if possible, and I am not alone in preferring this way to the other when stands are close in merit.—JOHN LAMBERT, *Powis Castle Gardens.*

## GRAFTING CHRYSANTHEMUMS ON ANTHEMIS FRUTESCENS.

MONS. J. EVERAERTS writes from Antwerp: “I send you the January number of the ‘Revue de l’Horticulture Belge,’ thinking that the article on grafting Chrysanthemums on *Anthemis frutescens* might interest you, and perhaps some of the readers of your Journal. We have ourselves tried the experiment, and thus far have a hopeful opinion about the future of the new method.” We are much obliged to M. Everaerts for drawing attention to the article, which is by M. Alexis Callier, and is of much interest. Many readers may be glad to know what the Belgian horticulturists are doing with *Anthemis* (*Chrysanthemum*) *frutescens* as a stock for Chrysanthemums, and we therefore translate the article.

“The ‘Revue’ asks me for some information on the subject of grafting Chrysanthemums on the *Anthemis*. I have nothing to say as to the results obtained. Some grafted plants were seen at the November Exhibition in Ghent. They were, however, only the results of one trial, and I am convinced that they may be greatly improved upon. I have been asked how I discovered the new method. It is very simple, I did not find it, and it is not new. I have imitated the Chinese, who use it readily, as witnessed by Fortune, reported by Burbidge (*The Chrysanthemum*).

“The idea came to me to follow their example in observing the great vigour developed by certain *Anthemis* under the influence of manure. The *Anthemis* being hardy, or, at least, conserving its trunks and stems, the Chrysanthemum ought to profit, by means of the graft, by the superabundance of sap in the stock, and above all of the strength already acquired by the latter when the shoots of the Chrysanthemum have only just commenced to push. This strength might represent the work of weeks, months, or even years. In two years the *Anthemis*,

submitted to high culture, is a small tree. In the south of France, where it grows out of doors and withstands the winters, it is not rare to meet with specimens of a size unknown in our more northern country.

"No doubt the graft would succeed with all the varieties of *Anthemis frutescens*, but there is an advantage in choosing as stocks those of which the growth is the most rapid. From this point of view no variety surpasses *Etoile d'Or*, little cultivated by us, but nevertheless known by its beautiful flowers, resembling large yellow *Marguerites*, which reach us during the winter from Nice and Cannes. Next to this is another variety of which the flowers are like large white *Marguerites*, long extensively cultivated on balconies, but of which I do not know the name [possibly *Halleri maxima*]. With the one and with the other variety I have obtained nearly equal results. In all probability some *Chrysanthemums* have a greater affinity for one *Anthemis* than for another, as some *Roses* prefer the *Manetti* or the *Multiflora de la Grifferaie* for a stock. It is a subject for study.

"It may be said at once that in our first attempts, or rather in our early gropings, all varieties of *Chrysanthemums* did not lend themselves equally to the graft as we practised it. More skilful culture than ours, and the common efforts of those who will interest themselves in the matter will show, we are inclined to think, that there are few really refractory. We have succeeded with the following varieties:—*Val d'Andorre*, *Paul Fabvre*, *Ernest Fierens*, *Mélanie Fabvre*, *Etoile de Lyon*, *Hiver fleuri*, *Mdlle. Paul Dutour*, *Madame Eliza Neyt*, *Source d'Or*, *Cinna*, *Cavour*, *Marie Fierens*, *Sirius*, and *Hermann*. We have failed with *Mrs. Parnell*, *George Glenney*, *Mrs. Dixon*, *Edwin Molyneux*, *Mrs. Haliburton*, *Vital* (sown 1890), *Marsalia*, *Maiden's Blush*, *Osaka*, *Guernsey Nugget*, and *Madame C. Audiguier*. Even in their case the union took place, but was more or less spoiled subsequently, as testified by the feeble growth of the plant.

"I invariably grafted *à la Huart* or *à la Pointoise*,\* with a ligature of raffia, covered or not with mastic. I did not perceive any difference by the use of the mastic. The union of the stock and scion should be made as exact as possible—bark against bark—by choosing growths of the same size. The plant should be kept close under glass for about three weeks, a little more or less according to the caprices of the graft, giving air gradually as if in the case of cuttings. The temperature should be 12° to 15° C. (about 53° to 59° Fahr.) by artificial heat; 15° to 20° C. (59° to 68° Fahr.) by natural heat. Shade against the direct action of the sun if the rays have acquired much force. Leave the ligature for some time in order to force the stock and scion to penetrate each other reciprocally. As the plants develop successive repottings will, of course, be necessary.

"The period at which grafting may be performed is from the commencement of December to the commencement of May. It depends on the resources at disposal, and the results desired. Early and late grafting both have advantages. In grafting early on an *Anthemis* having only a few branches a small number of *Chrysanthemum* shoots will suffice to produce a very large plant by the following November. A plant of *Ernest Fierens* was grafted in January on an *Anthemis* struck from a cutting in August, 1891; the stock bore only nine grafts, but, thanks to attentive pinching, it gave more than 300 flowers. But in grafting late, in March for example, the operation is more sure. None of the delicate attentions are required by the plants, such as they need in the winter months. On the one part an *Anthemis* may be allowed to push, which will grow like a weed, and as many stems as possible should be induced to push by pinching. As its growth is much more vigorous than that of the *Chrysanthemum*, the multiplication of its stems proceeds far more quickly; in spring the stock is full of health and vigour. At the same time as many shoots of *Chrysanthemums* are secured, either by cuttings or by allowing the old stools to push, as will be required for grafts, and an endeavour is made to have them as vigorous as possible. The moment come—in March, for instance, the stock and scion are both in full vigour, and the ulterior development of the plant can only be favourable. The rapidity of growth of the *Anthemis* is such that grafts effected in April on *Anthemises* raised from cuttings in January give larger plants than those resulting from *Chrysanthemum* cuttings struck in November. But naturally the larger the *Anthemis* the larger the grafted plant. In taking an *Anthemis* of one or two years, and placing on it in February or March 100 grafts, or even more, specimens may readily be produced having 1000 or 2000 large flowers, and a diameter of 3 or 4 yards. To arrive at this result it is necessary to take timely steps, preparing the stock on the one side, and a sufficient number of grafts on the other.

"What will happen with the grafted plants which have flowered in the second year? That is still the secret of the future. I incline to think that they will push and flower again. All those which I preserved emitted shoots just above the graft, exactly like those produced round the stool of a *Chrysanthemum* after flowering. These shoots, profiting by the sap of the *Anthemis*, ought, I think, to develop normally. I will speak about this another year."

Perhaps some of our *Chrysanthemum*-growing readers will experiment in the direction indicated by M. Callier, and communicate the results in due course. There is still abundant time for the operation to be performed.

\* This graft requires that the stock be cut at its extremity *en biseau*, so as to exactly join the two cuts. This biseau is hollowed like a V so as to receive a graft, of which the extremity is cut so as to fit the cavity in the stock.

## SCOPOLIA FLADNICHIANA.

THIS comparatively little known plant was exhibited at the Drill Hall on Tuesday, March 14th, by Messrs. G. Paul & Son, The Old Nurseries, Cheshunt, and was adjudged an award of merit by the Floral Committee of the Royal Horticultural Society. It is rather a robust growing herbaceous plant, with bright green leaves, and pretty bell-shaped pale yellow flowers.

Regarding *Scopolia Fladnichiana*, Messrs. Paul & Son write:—"This plant seems perfectly hardy on the summit of our rockwork. It is a Central European plant—Hungarian or Bohemian—and blooming as it does early in March with flowers apparently frost-proof it looks like a

FIG. 49.—SCOPOLIA FLADNICHIANA.

valuable addition to the hardy spring flower garden." Fig. 49 represents the flowers and foliage.

## PRESTON SPRING SHOW.—MARCH 15TH AND 16TH.

THE fifteenth Show of flowering spring bulbs and plants and cut flowers, held under the auspices of the Preston and Fulwood Horticultural Society, took place in the Public Hall, Preston, on the above dates. This was the finest Exhibition held since its formation. There were ten more exhibitors this year than last, and the number of entries was 363, an increase of fifty-six.

In the amateurs' class Mr. J. B. Dixon was first for twenty-four single Hyacinths; Mr. Payne taking similar honours and twenty-four doubles in the nurserymen's class. The double Hyacinths, though well shown, were not quite so good as we have seen them. The Tulips were fine, but not fully developed, requiring a few more days to bring them to perfection. The *Deutzias* were remarkably good, especially those shown by Mr. J. B. Dixon, and being the most meritorious, was awarded a silver medal. The *Lilies of the Valley* made a grand show. The *Narcissi* were not so well represented as last year, although there were some fine examples amongst them. *Primulas* and *Cyclamens* made a fair display.

There were several beautiful groups of plants staged for effect in the nurserymen's class. The first prize was taken by Mr. Payne of Fulwood, whose group contain many spring flowering plants, including a fine

Imantophyllum, whilst the background was composed of large Palms and Ferns. The first prize group in the amateurs' class was shown by Mr. J. B. Dixon, Ashton House, Ashton. The latter exhibitor was also first for six Azaleas, very fine and fresh examples. There was a great falling off in the show of Orchids, owing chiefly to the breaking up of a local Orchid establishment.

The wreaths, crosses, brides' and hand bouquets were excellent, and the competition was keen. Mr. Troughton was first in each class, the arrangements were splendid, being light.

For twenty pots of miscellaneous bulbs in flower, distinct, Mr. Frisby, gardener to Miss Ffarington, Worden Hall, Leyland, was first; and for six pots of Roses, first, Mr. Williams, gardener to J. Whitehead, Esq., Priory, Penwortham. Mr. Lamb, gardener to R. Smith, Esq., Longridge, was first for six dinner-table plants. Mr. Sharples, gardener to J. B. Dixon, Esq., Ashton House, Ashton, was also first for Azaleas, Hyacinths, Cyclamens, and Cinerarias.

There was a fair show of collection of vegetables, six varieties, Miss Ffarington, being first. The cottagers' class was well represented. The Judges were Mr. Bardney of Osmaston Manor, Derby, and Mr. McKellar of Abney Hall, Chcadle.

### GRASSENDALE AND AIGBURTH SPRING SHOW.

THIS Show, held on Saturday last, proved most successful. The exhibits were not only more numerous, but they were of excellent quality. Orchids were well shown, the Cattleyas making a grand show. Mr. A. Bryan, gardener to A. Garnett, Esq., staged a fine variety of Cattleya Trianae; Mr. J. Grant, gardener to W. S. Gladstone, Esq., Angraecum sesquipedale. Mr. J. Madeley, gardener to W. C. Atkinson, Esq., had a choice plant of Cypripedium Rothschildianum with five flowers; other Orchids of note being the quaint Oncidium undulatum, Cymbidium eburneum, and a number of Coelogyne cristata.

Hyacinths were good. For nine distinct, six distinct, and six pots three bulbs in a pot, the first prizes went to Messrs. J. Agnew, gardener to Mrs. Watts; John Kelly, gardener to R. Singlehurst, Esq.; and G. Leadbeater, gardener to Mr. W. J. Davey, Esq. Tulips were a very strong feature. The prizes for six singles and the six doubles went to Messrs. Agnew and Grant, the latter securing the prize for six pots of Narcissus. The prize for Amaryllis went to Mr. J. Pinnington, Aigburth, and that for two stove and greenhouse plants to Mr. G. Leadbeater for a well-flowered Azalea and a finely coloured Croton. Mr. Bryan had the best single specimen, and also won with Orchids.

For two Ferns Mr. J. Bounds, gardener to L. L. Jones, Esq., was first with Adiantum scutum and Microlepia hirta cristata, and Mr. G. Leadbeater staged a fine Davallia Mooreana 7 feet in diameter. He was also first for three Azaleas and a charming Rhododendron Gibsoni. For two Azaleas Mr. J. Bounds was first; the prizes for one Azalea and two hardy Rhododendrons were taken by Mr. J. Kelly. Mr. Bryan took first honours for two pot Roses, one bouquet, and a charming variety of six stove and greenhouse cut flowers. For three forced hardy plants, four table plants and three Carnations in pots, and six trusses of Roses Mr. J. Bounds was placed first. For three Spiraeas and four pots of Lily of the Valley Mr. J. Madeley took first honours.

Primulas and Cyclamens were in grand condition. Mr. E. Taylor, gardener to E. Pryor, Esq., was first prize for four Primulas, and Mr. T. Ankers, gardener to W. B. Bowring, Esq., in the class for Cyclamens; Mr. Ankers also secured first position for one Palm, one Mignonette, two hardy Azaleas, two Callas, and four pots of herbaceous plants. Mr. P. Green, gardener to L. H. Macintyre, Esq., was placed first for one hardy Azalea, whilst for Cinerarias and two Palms the prizes went to Messrs. Agnew and G. Burns.—R. P. R.

### ROYAL BOTANIC SOCIETY.—MARCH 22ND.

THE first Show of the Royal Botanic Society for the present year was more favoured in respect to weather than many of its predecessors. The Exhibition did not appear to be quite so extensive as usual, although it was of the usual bright and diversified character.

Hyacinths were, as usual, finely shown by Mr. Douglas, gardener to Mrs. Whitbourn, Ilford, the spikes being large, well balanced, and the foliage commendably dwarf. Electra, King of the Blues, Vuurbak, Koh-i-Noor, and La Grandesse were the best plants. Mr. H. Eason, gardener to B. Noakes, Esq., was second with fair trusses; and Mr. R. Scott, gardener to Miss Foster, third. Mr. Douglas was also to the front with Tulips, which were in beautiful condition when judged, the plants being dwarf, but the flowers large, Ophir d'Or, White Joost Van Vondel, Keezer's Kroon, and Proserpine being splendid, the latter especially. Mr. Scott was second with fine flowers, and Mr. Eason third. Mr. Douglas won again with Polyanthus Narcissi, Mr. Scott following. Messrs. H. Williams & Son won in the trade class with twelve Hyacinths, Mr. W. Morle being second. Mr. Douglas won with Crocuses in pots, brilliant masses of colour; Mr. Morle second, and Mr. Scott third. The prizes for Lilies of the Valley went to Messrs. H. Williams & Sons, Morle, and Scott in the order named.

Greenhouse Azaleas were exhibited in good condition by Mr. Scott, who was placed first. His plants were not large, but were healthy and well bloomed. Mr. Eason was second. Mr. Douglas scored his customary victory with Deutzias, the plants being wreathed in bloom, and Mr. Eason was a good second. Messrs. G. Paul & Son were the only exhibitors of six Roses, and were awarded the first prize for well flowered plants of Beauty of Waltham, Innocente Pirola, Magna Charta, Violette Bowyer, Celine Forestier, and Alphonse Soupert. Mr. Ware won with a

collection of hardy herbaceous plants, amongst them being Doronicum plantagineum exelsum, Spiraea japonica multiflora compacta, Ficaria grandiflora, Anemone pulsatilla, Primula cashmeriana, Epigaea repens, and Megasea purpurascens. Messrs. Paul & Son, Cheshunt, and Mr. Douglas were equal first with Amaryllis, the plants being very strong and carrying fine flowers in each case. Mr. Mowbray, gardener to Major the Hon. H. C. Legge, Fulmer, Slough, won with twelve pots of Cyclamen, the plants being splendid examples, large and densely furnished with bloom. Better are rarely seen. Mr. T. Prestridge was second, also with excellent material; and Mr. D. Phillips, gardener to R. W. Mann, Esq., Langley Broom, Slough, third. Mr. Douglas was the only exhibitor of Freesias, and was placed first for some large pots, well furnished with flowers.

The miscellaneous exhibits formed, as usual, a prominent feature. Messrs. Cutbush & Son had a brilliant display of greenhouse and conservatory plants, well grown and full of bloom (silver medal). Messrs. B. S. Williams & Son had a large and beautiful group, comprising a finely grown collection of Hyacinths and Tulips, Polyanthus Narcissi, Lilies of the Valley, Clivias, Rhododendrons, Orchids, and a few new plants, amongst which were Caraguata cardinale and the white Anthurium Williamsi (large silver medal). Messrs. Paul & Son, Cheshunt, had a group of new Roses and Lilacs. Amongst the former was the beautiful H.P., Paul's Early Blush, a lovely satiny blush with a delicate perfume. Jeannie Dickson was also conspicuous. Léon Simon was one of the finest of the Lilacs (large bronze medal). Messrs. H. Williams and Sons, Finchley, had an extensive display of Hyacinths, Tulips, and Daffodils (small silver medal). The St. George's Nursery Company were represented by a fine group of Cyclamens (small silver medal). Mr. T. S. Ware had a display of hardy plants and bulbs, comprising Primulas, Saxifragas, Chionodoxas, and Daffodils (bronze medal). Mr. T. Prestridge had a small group of well grown and finely bloomed Cyclamens (large bronze medal). Mr. H. Eason had some pots of Lachenalias full of flowers (certificate). Messrs. J. James & Son had a collection of their beautiful Cinerarias, the merits of which are well known (small silver medal). Messrs. J. Veitch & Sons sent several new plants, these including the handsome and graceful Pandanus Baptisti, also a number of Amaryllis, to which we shall shortly refer more fully. Mr. John Odell had a small collection of Cyclamens (large bronze medal). Messrs. Barr and Son contributed a bright group of hardy flowers, chiefly bulbous, comprising Sisyrinchium grandiflorum album, Iberis stylosa, and May Daffodils (bronze medal). Messrs. W. Paul & Son, Waltham Cross, sent a dozen boxes of cut Camellias, a beautiful display, and also a group of new Roses, in which White Lady and Corinna were conspicuous (small silver medal). Messrs. Ryder & Son exhibited floral decorations (commended).

### HARDY FRUIT GARDEN.

**Strawberries.**—Established beds of Strawberries will need some attention now in clearing away old, blackened, ragged foliage which has suffered from the effects of frost and damp. At the same time remove the strawy remains of the autumn mulch if it be sufficiently decomposed and its virtues have been abstracted by the soil through the action of the winter rains. The operation is best performed in dry weather, and while doing so carefully lift with a fork any strong-rooted perennial weeds which may be present; weeds of annual growth destroy with the hoe. In clearing the ground use an iron rake, but avoid severing the matted fibrous roots round the crowns.

**Applying Spring Dressing.**—Apply immediately round each a good dressing of soot and lime. This will act in a most effective manner in destroying slugs, or at least in reducing their numbers, the dressing, after the first rain, also proving of benefit to the roots. A similar dressing, or of soot alone, may be given to recently formed plantations. Soot is an excellent stimulant, giving tone and colour to the foliage, and increasing the size of the fruit. The present time, or very shortly, is suitable to give a general mulching between the rows of fairly fresh stable manure, containing a moderate amount of straw. By the time the fruit is ripe the latter will have become so consolidated and washed clean that it will form an excellent base for the fruit to rest upon.

**Planting Strawberries.**—Strawberries can now be removed from nursery beds, and planted permanently in rows 2 to 3 feet apart, the plants themselves in the rows being 18 inches to 2 feet apart. The exact distances must be regulated according to the richness of the soil and the vigour of the varieties. The Strawberry likes a deep, well enriched, holding soil. The best preparation should, therefore, be afforded in manuring and digging the site selected. If such preparation has been given to the ground earlier in the season all the better, particularly in light soils, where before planting compression of the surface is necessary in order to ensure firmness. When the rows are formed at the wider distances it is a good plan during the first year to grow a single row of Lettuce, or plant autumn-sown Onions between each. This can be done without detriment to the Strawberries, and there is no waste of ground. In this case a general mulch is not

desirable, as it will be necessary to frequently use the Dutch hoe for maintaining a loose surface.

**Protecting Fruit Blossom on Wall Trees.**—It is well to have all the material for effectively protecting trees ready to hand; if possible adjusted in position, so that it can be conveniently extended over or in front of the trees when necessary.

**Methods of Protecting.**—All walls against which choice varieties of fruit trees are planted ought to be furnished with a projecting coping either of wood or glass. The advantage of having a projecting coping is found in the ease with which material can be fixed, drawn up and down, or on one side as necessary. Woollen netting or tiffany is the best material for protecting, and where a coping exists a series of brass rings should be fixed to the upper edges of the material used and be placed on an iron rod secured to the edge of the coping. Another set of rings at the lower end also running on an iron rod fixed 18 inches or 2 feet from the ground on convenient uprights fastens that part. The whole is easily extended or folded as required, slight wooden uprights being placed securely from the coping to the ground for fastening the material to when folded. In the absence of coping poles of sufficient length to reach the top of the wall, standing out at the foot well clear of the trees may be used, placing them 6 feet apart. On these stretch tiffany, frigi domo, cotton netting, double or treble fish netting, or pilchard netting. Protecting material should stand clear of the trees at least 3 inches.

**Protecting Pyramids and Espaliers.**—The best way of protecting pyramid trees is to fix three poles round each, equidistant, firmly fixed at the foot, splicing them together at the top well clear of the trees. The protective material must be wound round tightly, not closing up the apex, nor carrying it to the bottom within 2 feet. Espaliers in the open may have a pole arrangement on each side, the tops being fastened above the trees. In cases where the trees are close to walks the base of the poles may be steadied by being fixed in pots, small tubs, or boxes filled with soil, ashes, sand, &c., but usually the poles on one side can be made firm, which will help to hold the others. By stretching frigi domo from each support the trees will be effectually guarded from frost destroying the blossoms.

#### FRUIT FORCING.

**Vines.**—*Earliest in Pots.*—Those started last October to early in November have the Grapes at the colouring stage, and require supplies of tepid liquid manure to insure well-swelled berries. A little air constantly aids the ripening process, but an arid atmosphere should be avoided by damping available surfaces occasionally. Do not curtail the laterals before the fruit is finished, when they may be reduced, especially if the Vines are required for table decoration and have been allowed to root from the pots, the simultaneous reduction of the roots and laterals being necessary to preserve the remaining foliage in good condition.

**Early Houses.**—The Grapes will soon proceed with the colouring process, and, as they swell considerably during that stage, the Vines should be well supplied with tepid liquid manure. The border may also be mulched with partially decayed, well sweetened manure, an inch thickness sufficing. A good watering and the mulching will generally be sufficient for the Vines until the Grapes are cut, but the soil must not be allowed to become dry so as to distress the foliage, for that should be preserved in a healthy condition, its retention being essential to prevent premature growth. Continue damping at closing time until the Grapes are well advanced in colouring, and maintain a circulation of warm air constantly. Keep a good spread of foliage over Black Hamburgs; white Grapes require more light.

**Succession Houses.**—Disbudding, stopping, and tying the shoots must be attended to, for work of this kind falling into arrear cannot be satisfactorily brought forward. Stop the shoots one or two joints beyond the show of fruit where the space is limited; but where the restriction of space is less allow more extension to the shoots and laterals. The shoots may be pinched at three or four or more leaves beyond the bunch, and the laterals allowed to extend until the space is fairly occupied. Then keep them pinched, not permitting growth to be made that must afterwards be reduced in quantity. Vines in flower should have a circulation of warm rather dry air, and a temperature of 65° to 70° at night for Black Hamburgs and similar varieties; Muscats require a night temperature of 70° to 75°, and 10° to 15° more by day with sun. Shy-setting sorts should have the bunches brushed over with a camel's-hair brush, so as to rid the stigmas of the glutinous substance and the adhering "caps" about the time the blossom is fully expanded, choosing a warm part of the day after the house has been rather freely ventilated. Any varieties deficient of pollen may have it applied, collecting it from those that afford it freely. Free-setting varieties may be thinned as soon as the berries are formed, but the shy setters ought not to be thinned until the properly fertilised berries are taking the lead.

When the Grapes have been thinned and are fairly swelling, supply tepid water or liquid manure. Top-dressings of approved fertilisers are highly beneficial, applying them after the soil has been made moist, and washing in lightly. A light mulching of sweetened lumpy manure is useful, provided it is kept moistened by damping occasionally, especially at closing time. Admit a little air by the time the sun acts on the house, and increase it liberally as the temperature rises, so as to secure sturdy wood and thick leathery leaves. Close early, with plenty of atmospheric moisture, so as to run the heat up to 85° or 90° by the sun's agency, and allow the night temperature to fall to between 60° and 65° by the morning.

**Late Houses.**—The Vines started at the end of last month or beginning of this will now be swelling their buds, and should be syringed rather freely in the morning and at closing time, striving to secure a good

break by closing the house with a rather humid atmosphere of 75°. Young Vines must be brought into a horizontal position or lower, otherwise the sap rushes to the upper part of the canes and causes the buds to push unevenly. Moisten inside borders by watering as necessary, and on outside borders place a little protective material to prevent chill from snow and frost.

Houses of the late varieties not yet started should be set to work with as little delay as possible, for they require a longer season of growth than is sometimes given them, as when they start naturally, to produce highly finished Grapes, and such as will keep well. Syringe the rods several times a day, and maintain a moist atmosphere by damping the floor and border every evening. The night temperature should be kept at 50° to 55°, the latter by artificial means in the daytime, and 65° by day from sun heat.

Where Black Hamburg Grapes are required late the Vines may be permitted to break naturally, then the Grapes will be fit for thinning early in June, and they will ripen in September. When ripened early the berries are liable to lose colour and to shrivel by hanging, which is a great defect in Grapes, and is best prevented by a good, but not excessive, spread of foliage, and a properly moist condition of the soil, with sufficient ventilation to prevent damp.

**Ripe Grapes.**—Those in the Grape room have kept upon the whole satisfactorily, they having required more air than usual, perhaps due to the changeableness of the weather. Lady Downe's has proved, as usual, the best keeping Grape, taking colour, plumpness, and quality into consideration. Gros Colman also has preserved its freshness, and the quality is so improved by keeping as to be little inferior to Black Hamburg. Examine the Grapes twice a week for decayed berries, remove empty bottles, and replenish others with water as required.

**Figs.**—*Earliest Trees in Pots.*—Early Violet and St. John's varieties that were started in gentle bottom heat in November are now beginning to take their last swelling of the fruit for ripening, and to insure flavour a drier condition of the atmosphere and a higher temperature, with increased ventilation on fine days, is desirable. The larger fruited varieties, however, have not the fruit sufficiently advanced to admit this being done without prejudice to their crops. Anything approaching dryness at the roots must be avoided, yet lessened supplies are needed than when the fruit is swelling. Brown Turkey and similar varieties should have good supplies of tepid liquid manure twice a week, and the top-dressings be replenished, lumpy manure absorbing moisture when the trees are syringed, and gives off genial vapour for some time afterwards. Syringe twice a day when fine, once only when the weather is dull, the second syringing being given in time for the foliage to get fairly dry before night. Maintain a night temperature of 65° when mild, 70° to 75° by day, and a heat ranging between 75° and 85° with sun. Stop and thin the side shoots, as Figs enjoy light, full exposure to sunshine, training terminals forward where space admits or there is need to preserve the symmetry of the trees, always guarding against overcrowding.

**Succession Houses.**—Trees in borders require liberal supplies of liquid manure or copious waterings through a good, but not heavy, mulching of manure. Syringe twice a day unless dull, when once suffices, or not that when the weather is close and moist, but damp the paths and walls frequently, and again moisten the mulching when it becomes dry. This is better than keeping it constantly saturated. Ventilate freely in the early part of the day, but maintain a temperature of 75° to 85° from sun heat through the day, and close with a brisk heat and plenty of moisture about three o'clock in the afternoon. Maintain a night temperature of 60° to 65°, and 65° to 70° on dull days, with a little ventilation.

**Late Houses.**—Figs ripen one crop in a season in unheated houses, but the late varieties Nebian, Col di Signora Bianca, and Agen require fire heat to ripen the fruit well. The house must have a full exposure to the south. Well-drained, narrow, inside borders are best. The growths should be trained about 16 inches from the glass. Prune the trees and dress them with an insecticide, being careful not to injure the embryonic Figs, nor break the points of the shoots. Supply water so as to thoroughly moisten the soil, and keep the trees dormant as long as possible; but when they begin to grow afford generous treatment, admitting air soon, and closing early in the afternoon so as to husband the sun heat. Avoid, however, a close atmosphere, as that hinders the proper formation of the foliage, and too hasty treatment may cause the fruit to fall.

#### PLANT HOUSES.

**Crotons.**—Good heads that were notched and mossed some time ago will be sufficiently rooted for taking off and potting singly. Place them into 5 and 6-inch pots, and put in the propagating or other frame until they are established. The old plants from which heads are removed may, if stock is needed, be kept for yielding side shoots, otherwise they should be cut close back. Repot young plants that need more root room without delay. Syringe these plants freely and maintain a close warm atmosphere. No shading is needed; if the plants are grown in mixed houses of plants they should be arranged at one end or in any position where they can enjoy plenty of light, while the others can be shaded when occasion requires.

**Dracænas.**—Those that have been mossed may be taken off and placed into pots suitable for the purpose for which the plants may be required. Narrow-leaved kinds are most useful in from 5 to 7-inch pots for table and other forms of decoration. Give the plants similar treatment advised for Crotons until they are well rooted, afterwards shade them from bright sunshine. These plants will bear exposure to the sun; but they colour too highly, and the ends of the leaves

are very liable to decay. A fair amount of light is necessary to develop the fine colour of many varieties. The main portion of the stem may be cut into pieces and placed in pans if stock is needed. *D. Grielfoylli*, when raised from root cuttings, have green lower leaves, which detracts from the effectiveness of the plants. To have this variety in its best condition well-coloured heads should be re-rooted. Plants of *D. Goldiana* that have become too tall may have the tops taken off and inserted in 4 or 5-inch pots. When taking off the heads cut to where the wood is moderately soft. When this is done, and the pots are plunged in brisk bottom heat, they root quickly without losing a single leaf. A few of the eyes below where the head has been removed may be inserted with a leaf attached; these soon root, and form neat plants. For stock the old stems should be retained and allowed to break, when the side shoots can be taken off and rooted. *D. gracilis* may be treated in the same way.

**Poinsettias.**—Cut close back all old plants that it is intended to retain for another year. These if placed in an intermediate temperature will soon break into growth, when shake the old soil from the roots and repot the plants. Where it is necessary to increase the stock insert portions with two joints of well ripened wood in sandy soil in thumb pots and plunge them in the propagating frame. Rooting cuttings of ripened wood is the quickest and best method of raising a stock of these plants. As soon as these cuttings are well rooted they should be given an intermediate temperature so that sturdy growth will result.

**Euphorbia jacquiniæflora.**—Plants that have enjoyed a good rest may be placed into heat until they break into growth. When they have made growths 2 inches or a little more in length remove the plants to cool moderately airy quarters to harden the cuttings, when they may be taken off with a sharp knife and inserted in sandy soil and covered with bell-glasses in brisk heat. Do not place them in the propagating frame. If the cuttings are inserted in a soft condition when produced in brisk moist heat nearly every one will fail, but when well hardened the majority will root.

**Justicia flavicom.**—Cuttings of this useful plant should now be plentiful, and they root freely in sandy soil in the propagating frame. Insert each cutting singly so that the plants can be grown afterwards without a check. If sufficient cuttings can be obtained at once the old plants may be cut back and then allowed to break into growth. When in this condition reduce the old balls carefully, and repot the plants, placing them again in the same size pots.

**Begonia hydrocotylifolia.**—Plants that have done flowering may have all the old leaves removed. About 4 inches of the stem should be inserted as cuttings in small pots, for they root freely in sandy soil in a vinery or any house that is kept warm. If a large stock is needed the stem may be cut into lengths of 1 inch and placed in thumb pots. In the conservatory it is very effective with its light spikes of pink flowers rising above other plants. When in brisk heat the flowers are of the palest description, and the plant is not half so effective as when it is developed under cooler conditions.

**Acalyphas.**—Tops that were inserted as previously advised will be well rooted and should be placed into 5-inch pots. Grow these in brisk heat fully exposed to the sun, when their foliage will colour splendidly. For conservatories that are not kept too cool these *Acalyphas* plants will certainly replace *Coleus*, inasmuch as they will stand in these structures all the summer. Side shoots root freely in handlights in heat.

**Caladiums.**—Grow the earliest plants at present fully exposed to the sun and give a little air daily. This is necessary if the plants are to be employed in conservatories and other structures that are not kept close. When grown under moderately hardy conditions they stand well in rooms and in cooler houses after the middle of June. Plants that have been kept at rest may be started into growth without delay.

**Palms.**—Light shade should be given these during bright sunshine. Clean any plants that need it, and syringe freely to keep spider and thrip well in check. Pot any plants that need more root room. The majority of these plants do well in good loam and coarse sand, with a little artificial manure applied occasionally to the surface. Young plants may have one-third good leaf mould incorporated with the loam, while the more delicate-growing kinds prefer at least half peat. Maintain a moist atmosphere, and a temperature at night of 60°. If lightly shaded during bright sunshine the ventilators for the present may be kept close.

came in. I know there is no damp about my hives to injure them, consequently no dead bees upon the floors, as is the case with those having solid ones; and as the doorways are all narrow there is no draught to further chill the bees, which deters breeding, nor lack of food which has the same effect, and often ruins the hives and the prospect of the bee-keeper.

#### FEEDING.

Except in special cases during the autumn I have abandoned all top feeders. They are more troublesome than under fountains and scoops, and are liable to cause a draught. Bees will feed readily from under feeders, when they reject syrup in upper ones. With the use of under feeders the warm covering on the top of the hive is left intact, and no unnecessary cooling the temperature of the interior of the hive takes place or is permitted after October or November, up till the end of May, or perhaps later.

I have a strong aversion to feeding during the spring months, but it would be extremely foolish to advise against it in cases where the bees may be starving. Feed all such hives at once, even although the weather be unfavourable. Remember, however, that "brood spreading," untimely, stimulative, and excessive feeding come under the same category, and is against profitable management. Bees require nothing to induce them to breed when in a healthy and normal state but Nature's sunshine and flowers from this time and onwards till the end of December, when they depend upon the stores within their hives. That it is necessary bees should be fed at certain times, when their stores are exhausted and Nature fails to give a new supply, I never denied; but I question the soundness of the advice that bees should be supplied with syrup in a manner and at times so much advocated by certain persons if bee-keeping is to be a success. The fact that bees never fed, whether in hives or in roofs of houses, give the largest yields of honey is sufficient evidence in favour of non-fed hives, and supports my argument.

#### HIVES.

The beginner is very apt to be led away by the teachings of unpractical persons. Experience is the most reliable teacher, and the information flowing from it is really valuable. Long experience has proven to us that deep, but narrow, hives are most suitable for bees, and are the most profitable. The ventilating floor in our hives is an inestimable gain in the saving of bees during winter, the manipulation and the management in the apiary at home, also when in transit to and from the Heather. I only ask your readers to consider for a moment the comfortable state of a well managed hive so equipped with its narrow doorway, contrasted with one having a solid floor lowered with the vain attempt to dispel the accumulated damp so fatal to bee life. Damp, moreover, is aggravated by having a wide doorway, and tends to kill the bees. It is impossible for them to keep up the heat of their bodies at a zero temperature when located in ill ventilated, draughty, and damp hives. The bees are restless when they should be in a state of repose and comfort.—A LANARKSHIRE BEE-KEEPER.

## TO CORRESPONDENTS

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Netting Fruit Trees in Blossom (R. J. H.).**—The nets should hang distinctly clear, and not touch any portion of the trees. Perhaps no better guidance can be found than in the article on page 194 (March 9th). It is there stated that the foot of the supports for the nets to rest on may be 18 inches from the base of a wall 10 feet high, and 2 feet from the base of a wall 12 feet in height. You will also find in the article (page 195) the great value of glass or wood copings in addition to nets. Perhaps the mean between the two extremes you indicate, but do not define, will be the best solution of the problem. Be this as it may, we know from long experience that correct methods are clearly stated in the article referred to.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### THE WEATHER.

THE weather has continued cold ever since January closed, and there has not been much opportunity to feed strong hives, and none for weak ones. It is a repetition of the past; bees will feed in January when they will die in March. The latter is a treacherous month for bees, and they should be kept quiet and not induced to leave their hives on any pretext whatever. They have obtained no good from any of the spring flowers, and the Croci have never opened their petals. The Punicas, with few exceptions, are the only bees here that have carried pollen to any extent. I have no wish to see my bees much on the wing until the temperature rises to 55°, and 44° is the highest it has reached since March

## DAHLIA ANALYSIS

1883-92.

—x—

THE Exhibition held at the Crystal Palace in September last by the National Dahlia Society proved in many respects one of unusual interest, while all sections were well represented. The number of Show Dahlias fell somewhat short of the average; but the Fancies were more numerous than in any of the four previous years. The show of Pompons was also larger than at any of the recent exhibitions. The advance made by the Cactus and Decorative varieties during the last few years is truly surprising. In 1889 only seventy-four sets of blooms of these were staged, whereas at last year's Show there were 209, or nearly three times as many. The Singles also now add greatly to the interest of the display, and year by year are shown in larger numbers.

In the short statement which follows is given the total number of Show and Fancy Dahlias staged in competition at ten Crystal Palace Exhibitions, also the number of Pompon, Cactus, and Single Dahlias at the last four of them.

	1883	1884	1885	1886	1887	1888	1889	1890	1891	1892
Shows ...	692	754	837	840	1106	1158	922	934	854	879
Fancies ...	269	425	355	387	350	315	274	283	286	340
Pompons .	—	—	—	—	—	—	147	214	193	267
Cactus and } Decorative }	—	—	—	—	—	—	74	156	158	209
Singles ...	—	—	—	—	—	—	50	95	124	138

It might be thought that the longer the period over which an investigation of this kind extended the more reliable would be the averages obtained for the different varieties, and consequently the more satisfactory the relative positions assigned them in the tables. This would undoubtedly be the case but for the frequent introduction of new kinds, for the most promising of which places have also to be provided. In this way the older varieties either become gradually elbowed out of the lists altogether, or have to take in most cases inferior positions. When I had only the results of a few years before me these downward movements were not so apparent, but now that I have tables giving the exact numerical values for all the older Show and Fancy Dahlias for each of the last ten exhibitions, and those for the newer kinds since the time of their first introduction, the effects of these changes is at once seen.

In order to give each variety the position it is at the present time entitled to occupy, and the tables a more practical value, I have this year recalculated all the averages. Some few of the older sorts have an average given them for the full ten years, others for nine, eight, seven, six, and even five years as the case may be. In fact, the claims of each variety, whether new or old, have been decided entirely on its merits. Take, for instance, the Hon. Mrs. P. Wyndham, for some years the premier show flower, in the first half of the past decade, was shown on an average twenty-four times, but in the latter half only thirteen times. I could easily multiply examples of this kind, as there are comparatively few Dahlias which in the course of ten years do not show some signs of decline in public favour. On the other hand, varieties are occasionally to be met with which have been more

frequently shown in the second five than during the first five years. William Rawlings, for example, gives an average of eighteen for the first half of the period, and of twenty-six for the second half. Then, again, there are some kinds like Ethel Britton which show no decided indication either of advance or decline during the ten years. The above examples will sufficiently indicate how unfair it would be with these facts before me to treat all the varieties, as has hitherto been done, precisely alike. The averages have again been so calculated that the varying extent of the exhibitions does not in any way interfere with the comparable character of the results.

Of the seventy Show and Fancy Dahlias which secured places in the tables for 1883 only forty are to be found anywhere in the present lists. Moreover, no fewer than forty varieties are now tabulated in the analysis which were not even in existence when the first one appeared in 1883. Very considerable progress in the improvement of the Dahlias in both sections must, therefore, have been made during the decade under review.

In the table of Show Dahlias, Mrs. Gladstone (No. 1) for the seventh year in succession takes the premier place, and there is as yet no indication of its claim to that proud position being seriously contested. Of other established varieties, Mrs. Langtry (No. 6); Shirley Hibberd (No. 15); and Harrison Weir (No. 17) have seldom, if ever, been as numerous represented as at last year's exhibition. On the other hand, Henry Walton, Hon. Mrs. P. Wyndham, Prince Bismarck, Goldfinder, Mrs. Harris, and other good Show kinds were staged much less frequently than usual.

Of the 1889 varieties on the list Maud Fellowes (No. 10) and W. Jackson (No. 48) have made no advance on the positions they previously occupied. Glowworm (No. 42), however, was unusually well shown at the last Exhibition. There are four kinds introduced in 1890—John Hickling (No. 30), Alice Emily, and Duke of Fife (No. 34), and Crimson Globe (No. 46). John Walker, only distributed in 1892, on its first appearance takes a remarkably promising position at No. 13; while Arthur Rawlings of the same year will be found already as high as No. 30, and Arthur Ocock at No. 39.

Turning now to the Fancies, we still find Mrs. Saunders and Rev. J. B. M. Camm, both first sent out about twenty years ago, heading the list. They were in excellent form at the last Show, as were also Duchess of Albany, Frank Pearce, and H. Glasscock. Gaiety, on the contrary, has only once before been as poorly staged: while Mrs. N. Halls, Flora Wyatt, George Barnes, and Rebecca have also seldom been as badly represented.

The two 1889 Fancies, Mrs. J. Downie (No. 4) and Matthew Campbell (No. 5), well maintain the excellent places they secured in the last analysis. T. W. Girdlestone (No. 9), distributed in 1890, has greatly improved on its last year's position. Of the new sorts sent out in 1891 and 1892 Comedian (No. 23) and Mrs. Ocock (No. 23) were both creditably shown considering the recent dates of their introduction.

The following short lists have this year been arranged on similar lines to those drawn up for the Show and Fancy Dahlias, otherwise many of the best new sorts would have been excluded from them. The Pompon varieties readily lend themselves to tabulation, but neither the Cactus nor the Single kinds are as yet sufficiently established to allow of this being satisfactorily done. The gradual separation of the more or less true Cactus from the Decorative varieties by the National Society has been a step in the right direction, and has already borne good fruit in the introduction during the last few years of good new sorts of the true Cactus type, while several valuable additions to this popular section are, I understand, shortly to be sent out. Indeed, one of the most interesting features of last year's exhibition was the fine display of new Cactus Dahlias recently raised by Messrs. Keynes, Williams & Co.

POMPONS.—E. F. Junker, Darkness, White Aster (Guiding Star), Favourite, Grace, Isabel, Lady Blanche, Phoebe, Whisper, Admiration, Dora, Leila, Red Indian, Rosalie, Cupid, Fairy Tales, Gem, Golden Gem, and Mabel. Phoebe stands high for an 1891 variety, while Achilles of the same year was well shown, also H. E. Searle sent out in 1890.

CACTUS.—Duke of Clarence, Juarezii, Robert Mayher, Marchioness of Bute, Panthea, St. Catherine, Delicata, and Kynerith. The three last-named were only sent out in 1892.

Of the still newer varieties, Countess of Radnor and Bertha Mawley are of sterling merit.

DECORATIVE.—Mrs. Hawkins, Amphion, Empress of India, Honoria, Mrs. Douglas, Black Prince, Charming Bride, and William Darvil.

SINGLES.—Amos Perry, Miss Henshaw, Victoria, W. C. Harvey, Chilwell Beauty, Duchess of Fife, Florence Fisher, Marion Hood, Miss Roberts, Northern Star, and White Queen.—E. M., Berkhamsted.

## SHOW DAHLIAS.

Position in Present Analysis.	Average Number of Times Shown.	Number of Times Shown in 1892.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.

CHASSELAS NAPOLEON GRAPE.

IN your issue of March 22nd, page 229, you ask for an explanation respecting Chasselas Napoleon Grape for the benefit of the Grape-growing community. When I exhibited this Grape for a certificate before the Fruit Committee of the Royal Horticultural Society I did not represent it as a seedling Grape, or as a Grape of my own raising. I placed it before the Committee, as I considered it a Grape well worth their attention; and it was, I believe, unanimously awarded a first-class certificate. I herewith enclose a copy of my letter sent at the same time, which I think will conclusively prove that I have in no way attempted to regenerate this Grape.

[COPY OF LETTER SENT TO MR. BARRON.]

DEAR SIR,—I purpose placing before the Fruit Committee Chasselas Napoleon Grape for a certificate. It is, I consider, well worth their attention, as it is a good setter, keeps well, having been ripe since the beginning of September. It is also of very good quality. As it is growing here, not under the best advantages, being worked on an old Muscat stock, I think it would be a very fine Grape grown under more favourable circumstances. It is in the Muscat house which treatment seems to suit it.—Yours faithfully, GEORGE REYNOLDS.

P.S.—I cut bunches off the Vine late in November last year in excellent condition.

With regard to the origin of the Grape at Gunnersbury it was sent from Ferrières to my predecessor, Mr. Roberts. The vendors, Messrs. Cutbush & Son, who have procured the stock from me, inadvertently advertised it as a seedling of my raising through some misunderstanding on their part.

I have a Vine worked on the Muscat stock in the Muscat house here, and I have not experienced so much difficulty in setting it as there is with Muscats, and it has always carried a full crop. It has formed one variety, either in collections of five or ten varieties of Grapes when I have been exhibiting with as good results as most exhibitors. I shall be happy to show it anyone who is interested and so disposed to pay me a visit during the ensuing season, when they will be able to judge for themselves as to its cropping qualities.—GEORGE REYNOLDS, Gunnersbury Gardens, Acton, W.

LAST autumn at the Fruit Exhibition at Earls Court we noticed a white Grape exhibited by Mr. Reynolds of Gunnersbury Park Gardens; a great number of leading Grape growers observed that it was a fine white Grape, and would no doubt become a good

exhibition variety, and in the course of a few years would be amongst all collections upon the exhibition table. We neither saw nor heard anything further of the variety until we read Mr. Reynolds' advertisement in the "Gardeners' Chronicle" of February 18th, 1893, offering canes of Chasselas Napoleon Grape. As one of our representatives intended calling upon Mr. Reynolds during that week, we instructed him to endeavour to make terms with Mr. Reynolds to take over the entire stock for distribution, and an arrangement was come to subject to our confirmation. We wrote Mr. Reynolds immediately confirming the arrangement made, asking him to send full particulars of the Grape at once, as there was no time to lose, the season being far advanced for selling Vines. We received on March 1st full particulars of the Grape from him, and at once advertised in the press, as well as sending out circulars, giving full particulars of the Grape. Two or three days after we received a letter from Mr. Thomson of Clovenfords, saying that Chasselas Napoleon was a very old Grape and he had grown it thirty years. We at once wrote Mr. Reynolds enclosing Mr. Thomson's letter, and he replied, "You have made a mistake in advertising Chasselas Napoleon as a new Grape and as being raised by myself, as I procured the original from France." Immediately he informed us of this fact we withdrew all advertisements as well as destroying all circulars referring to the "new" Grape Chasselas Napoleon. We were until then quite under the impression that the Grape was a seedling and raised by Mr. Reynolds, and our impression was strengthened by knowing that the Fruit Committee of the Royal Horticultural Society had awarded it a first-class certificate on October 27th, 1891.

Now as to the quality of the Chasselas Napoleon Grape, we maintain that if the variety is properly grown as Mr. Reynolds has grown it, there is a good future before it. Our opinion is confirmed by many. In the first place we take the opinion of the Fruit Committee of the Royal Horticultural Society; would they be unanimous in awarding a Grape a first-class certificate unless there was some special merit attached to it? In the second place, would a great number of leading growers state that the variety would become a first-class exhibition Grape? In the third place, would the Horticultural Press write in such high praise of the Grape as they did when it was awarded a first-class certificate at the Royal Horticultural Society, unless there was some special merit attached to it?

What we say is this, it is an old Grape of very many years' standing, but has never been properly cultivated. If growers will only give it a fair trial, we are convinced it will be extensively

grown in the future. We do not hesitate to say we shall have a great demand for canes next autumn, and we are preparing a large stock to meet the demand. In a very short space of time Chasselas Napoleon will be in collections of Grapes upon the exhibition table.—WM. CUTBUSH & SON.

I DARESAY I was the first to bring the Chasselas Napoleon Grape under notice in a cultivated sense, when I exhibited an entire rod bearing eight bunches at one of the series of fortnightly exhibitions held in connection with the International Exhibition in Paris in 1867. I was induced to grow the Grape really for the name, and not for its merit, and indeed the same indifference caused me to cut out the entire two-year rod, as I had no intention of retaining the Grape as a produce variety. It was very imposing as shown in Paris, and it caused quite a sensation at the moment.

I obtained the Vine originally, amongst some fifty other varieties, from the late M. André Leroy of Angers as Panse Jaune. This, Monukka, and some others I retained, and grew them as far as possible to perfection, first in pots and then planted out in a new vineyard. The Chasselas Napoleon caused such astonishment at the time that I was besieged with inquiries concerning its origin and applications for eyes. My friend Mr. Thomson of Clovenfords had it also from me, and others, of whom I have no recollection. Suffice it to say that the Chasselas Napoleon is not a new Grape. I think I am right in saying that M. Ferdinand Jamin of Bourg-la-Reine gave Panse Jaune the synonym Chasselas Napoleon after I had previously shown it in pots at a meeting in Paris of the Société Impériale et Centrale d'Horticulture, for which I was awarded a medal in 1866.—HENRY KNIGHT, *Royal Parks and Gardens, Laeken, Brussels.*

[Mr. Knight's experience is in close accord with our references to Panse Jaune, syn. Chasselas Napoleon, and Mr. Reynolds' explanation shows what we suspected, that there had been some mistake or misunderstanding in reference to the so-called "new" variety. For this mistake we are bound to think that Mr. Reynolds is mainly responsible, as in a letter from him to Messrs. Cutbush and Son, dated March 1st, 1893, he says—"I have much pleasure in accepting your offer for my new Vine Chasselas Napoleon." The purchasers could not very well infer from this that the variety was an old one. His narrative proves the necessity for our remarks on the subject last week, and the facts of the case are now before the public. Comte Odart in 1854 gives Chasselas Napoleon as a synonym of Panse Jaune.]

## RHODODENDRONS.

So showy and beautiful are the numerous varieties of these hardy shrubs that no woodland walk or shrubbery can be considered complete without them, and for filling large beds in the flower garden or conspicuous positions near the mansion, the best hybrid varieties are especially suitable. When in flower they stand unrivalled among hardy shrubs for the massive trusses of their richly marked flowers. Having so many good qualities to commend them it is the more to be regretted that many cultivators are not successful in growing Rhododendrons, and therefore entertain the idea that they will not thrive in their locality. This I think is in many cases a fallacy. I am convinced that these shrubs will grow fairly well in almost any garden provided a reasonable amount of attention is bestowed upon them. They are not so fastidious in regard to soil as many would have us believe. I have seen them succeed quite as well in a deep somewhat heavy loam as in the best peat procurable; and in soils by no means rich, with due care good results may be obtained.

To be successful with Rhododendrons two things must be strictly avoided. These are: 1, Planting in soils containing a large percentage of lime or chalk; or 2, in positions where water frequently stagnates. The latter state of affairs frequently occurs in stiff clay soils, which only require to be brought into the right mechanical condition, as well as sweetened, by exposure to the atmosphere, to render success certain. Where planting has to be done in a soil of this description, it ought to be prepared during the autumn months. The soil should be taken out to a depth of 2½ feet, 9 inches of broken bricks or stones placed in for drainage, and pipes laid to carry away superfluous moisture. As the soil is returned to the bed large quantities of leaf mould or well decayed garden refuse ought to be mixed with it, and the surface soil ridged up to allow frosts and air to act beneficially upon it. Where this autumn preparation has been unavoidably delayed it may still be done, provided the soil is allowed to lie in a rough state for a couple of weeks before planting is performed. Some might object to planting Rhododendrons thus late, and I fully admit it would not be a wise proceeding if the plants were left to take their chance in regard to moisture at the roots, but in the majority

of gardens of the present day means are provided for watering shrubs when necessary, and under such circumstances planting may be safely done at any time before the flower buds swell, or after the flowers have faded. I have planted Rhododendrons in April, July, and August, and in each instance the results were equally satisfactory, a few good soakings of water being given when necessary.

I think far too much reliance is placed in peat for Rhododendrons, seeing they may be grown equally well without it. Good turfy loam without any other addition answers admirably, provided but little lime enters into composition. A great variety of soils will grow the shrubs well with but little preparation. Pure sweet leaf soil is good for the purpose, but I find well-decayed garden refuse still better. The kind we use for the purpose is formed of the sweepings of walks, leaves from shrubberies, and short grass taken from the mowing machines. These materials are thrown into a heap as collected. At the end of each year the heap is turned, the ingredients well mixed and piled into a wide ridge, where it remains for nine or twelve months before being used. It is then decayed sufficiently to be ready for use, with no other preparation than that of picking out sticks or stones as the carts or barrows are loaded. We collect and prepare large quantities of such materials, and always find plenty of ways to dispose of it in the shrubberies and herbaceous borders. All kinds of shrubs seem to have a decided liking for it, and wherever applied healthy growth and active rootlets soon follow. Whenever I find Rhododendrons becoming unhealthy, a little of the surface soil is removed till a few active roots are found, 2 or 3 inches of refuse is then given in the spring or early summer months, and I invariably find a marked improvement in the colour of the foliage and vigour of growth.

Another point in connection with the growth of Rhododendrons which I think receives too little attention is the desirability of keeping the beds clear, or nearly so, of other plants. A few Lilliums, Gladiolus, or other bulbous flowers look well, and supply a feature when the shrubs are flowerless without being to any appreciable extent inimical to the well being of the Rhododendrons; but in cases where such strong and quick-rooting plants as Musk and Winter Cherry have been planted beneath them the sooner they are uprooted the better, for they carry on deadly warfare against the hair-like Rhododendron roots, and in the end the latter must be beaten in the contest. Many Rhododendrons are seriously checked by the exhaustive process of seeding, and the withered flower trusses should be promptly removed.—H. D.

## BORDER FLOWERS.

THIS spring, so far, notwithstanding much frost, has been the best of many years. Hardy border flowers have not been so beautiful for a long time. Owing to the nature of the plants grown in the borders the greater number of spring plants are bulbous. Among these the early Squills are most charming. We have many large clumps of *Scilla præcox*, and also of *Scilla bifolia*. The prettiest of all is *S. b. alba*, which is quite a gem. We have also a rose form, which, however, is not so good. A great improvement on *S. bifolia* is found in *S. taurica*. *S. botryoides* is showing the blue in its spikes. The one fault of this pretty flower is the evil habit it assumes of spreading beyond bounds. Curiously enough the white form is extremely shy to propagate itself. This is unfortunate, as few flowers can rival it in beauty.

For some time Crocuses have been eminently beautiful. No doubt the extremely free-flowering yellow *Crocus* is the brightest of all, but in such fine weather as we are experiencing all the varieties are beautiful, whites, purples as large as Tulips, and many shades ranging intermediate between these. It is surprising that these are so sparsely grown in large gardens. Another particularly lovely flower is the Spring Snowflake, *Leucojum vernum*; a mass or a bed of this takes a good deal of beating. It is so good that not a small clump but a large quantity ought to find an appropriate place in every garden.

Of non-bulbous plants I like none better than the Polyanthus as improved to date. I have every year a border devoted to their special use. The plants are raised from seeds sown out of doors about the middle of March. During summer they are transplanted into the place where it is intended they should flower. About the end of March a slight dressing of manure is sprinkled among the plants and hoed in. The plants may be left a second year, when flowering will begin earlier. As a rule they are finest during April, but from March to May there is much beauty to be found both individually and in the mass.

*Iris reticulata* troubled me long through its much-dwindling habit. Sometimes indeed it died out altogether. For several years it has done well, and the only reason I have to account for

this is that the plants are dressed with fresh material applied to the surface once a year, and in addition a very slight application of superphosphate.

In passing I may say that the latter is a more important manurial agent than is generally supposed. I use a good deal of it in the course of each year. Just at present a very slight dressing is applied to growing flowers—*e.g.*, Tulips, Narcissi, summer Irises, Carnations, early Gladioli, Polyanthus, and to mixed borders; also to Cabbages, Spinach, Onions, and anything that appears to require a fillip. Later the crop of Celery, Carrots, and also bedding plants are treated. There is nothing gained by applying a heavy dressing. For instance, last year I set a man to dress a plot of ground, and when I went back to see how he progressed 2 cwt. had been spread over a superficies of 480 square yards. One-tenth would have been of more benefit to the crop. The general fault with those inexperienced with manures is to apply too heavily. The rule, which may have exceptions, is to dress lightly, and if necessary to dress often.—B.

### PROGRESS OF THE SPRING. IN A SCOTTISH MANSE GARDEN.

It is most interesting to mark the growth and development of the vernal flowers at this season of the year. Owing to the influence of the recent brilliant sunshine, followed in the calm June-like evenings by a gracious dew, much progress has been made. Every morning discloses to the thoughtful mind a new floral revelation. The Chinese Sacred Lily, which is essentially a Narcissus, exceedingly fragrant, but of somewhat unobtrusive attractiveness, is now in full bloom. So also is the familiar Wallflower, "with its homely cottage-smell" (to quote the expressive language which my friend Matthew Arnold applied to another and not fairer flower); while the lilac and pure white double Primroses are glowing everywhere. The Madonna Lily, called "candidum" by Virgil, and "argenteum" by Propertius, both expressive epithets, is growing very rapidly; a slower growth characterises the more delicate longiflorum; and the great *Lilium giganteum* of the Himalayas is just beginning to appear. Only one of the speciosums—*viz.*, the exquisite *Kraetzerei*, has made its appearance; but the *Kramerianum*, or Lily of Kramer, whose colour varies from palest pink to deep rose, has produced to my gratification four strong stems the first year from a single bulb, which surely beats the record. This is a Lily which, as I am informed by Dr. Wallace of Colchester, "rarely does well."

A Gloire de Dijon Rose growing on a wall with a southern aspect has produced its first bud, and many others will be visible within the next two days. The "Gloire" with me is the earliest Rose to bloom; in this respect it is usually in advance of the *Rosa rugosa*, Austrian Briar (*Harrisoni*), or Persian Yellow, which at present are only coming into leaf. Everywhere through the garden is seen the wonderful glow of the Daffodils, which as Shakespeare finely says, "take the winds of March with beauty;" but its golden masses are still more beautiful in front of this manse, beneath the leafless trees. The Snowdrops and the Crocus, having fulfilled their mission, are fast vanishing from our gaze. The Lily of the Valley, that loveliest of the flowers of early summer, is rapidly developing its latent resources, and will come into bloom prematurely this year. The Periwinkle is luxuriating in a remote corner of the garden, and on the flower border opposite the "Adelina Patti" and "Comte de St. Clair" Iris are exhibiting for the first time signs of vitality.—DAVID R. WILLIAMSON.

### DISCUSSION ON PEACHES.

I HAVE read with interest the articles about Alexander and Waterloo Peaches. I prefer the last named, as Alexander is very precarious, nor is the fruit equal to Waterloo. I lose a few buds of Waterloo in the early house, but always have a fair crop of fruit of high colour and good quality. I do not use the camel's-hair brush to fertilise the blossom, but for twenty-five years have used a rabbit's tail. This I skin and glue on the end of a long pointed stick. With this I reach to the top of the trees. I dew the trees with the syringe on fine mornings all through the blossoming and setting season.

When the buds begin swelling I rub off all the back ones, as I scarcely ever lose any blooms through the setting. I have Waterloo in the early house, which is a lean-to 75 by 12 feet. Last year I gathered from the tree on May 5th, and sent the fruit to Mr. Monro, Covent Garden. These were sold for 36s. a dozen. In 1891 I sent my first fruit to market on May 8th, and these made 24s. a dozen.

I also have Waterloo in the late house, which is 180 feet long, and not heated. The low front trellis and the back wall are planted with Peaches and Nectarines. In this house I gather Waterloo about the middle of July, and the fruit is very useful, as it comes in just after the early house is over. Hale's Early in the same house is ripe a few days

after Waterloo is over. Next come Early York, Grosse Mignonne, and Sea Eagle. The last named is a good market Peach. Lord Napier and Pitmaston Orange Nectarines are favourites here. I grow more Royal George Peaches than any other variety, as this is good for table and market, always cropping and colouring well.—W. MOWBRAY, *The Gardens, Fulmer, Slough.*

### NEW FRENCH ROSES.

(Concluded from page 238.)

As I have already indicated, there does not seem to be much hope of our getting anything very novel from our neighbours across the Channel, to whom we have been indebted for so many years for nearly all the lovely flowers which adorn our gardens and attract the notice of visitors at our exhibitions, but that time seems over, as I think may be gathered from two facts; one being that in the new catalogue of the National Rose Society I do not believe that there will be half a dozen considered worthy of a place amongst exhibition Roses of such flowers as have been put into commerce since the supplement was published; the other is that when we look at the list of new Roses sent out in the autumn of 1891 we find that thirty-four Teas, eight Hybrid Teas, and twenty Hybrid Perpetuals were announced, and I do not believe that one of them is known to be worthy of retention in our exhibition lists. Of course there may be a "dark horse" among them that may be at present unknown to fame, but the probability is that if there was anything very good we should have heard of it before now. We must therefore, I think, base our hopes of novelties upon our home raisers.

Your correspondent, Mr. Williamson (page 214), seems to be in a bit of fog about some of the Roses he has named. There is a wide difference between a seedling and a sport, which he does not seem to recognise. Thus, *Merveille de Lyon* is not a seedling, but a sport of *Baroness Rothschild*; *Duke and Duchess of Fife* are but sports of *Etienne Levet* and *Countess of Rosebery*, and not seedlings; *Souvenir de S. A. Prince* is a sport of *Souvenir d'un Ami*; *Augustine Guinoisseau* is a sport of *La France*, and not a seedling. As to Mrs. G. Paul, which, by-the-by, is not a Hybrid Bourbon, but a pure Bourbon, it is a seedling from that very vigorous Rose *Madame Isaac Pereire*. This may seem a digression, but it brings one face to face with the fact that it is amongst the raisers of our own islands, instead of those from France, that we are to look for additions. As far as Hybrid Perpetuals are concerned there is a more scientific system of hybridising practised amongst us. I take the Hybrid Teas first, not because I have any special love for them, but they come first in Ketten's catalogue.

#### HYBRID TEAS.

*Elise Schüle* (H. Geisler).—Brilliant cerise red flower, the petals clear and transparent, those in the centre edged with white; large, full, opening well, tulip-shaped.

*Lady Henry Grosvenor* (Bennett).—Carnation rose flower; large, full, ball-shaped.

*Mrs. Charles Bonting* (Vigneron).—Carnation red rose, shading off to light rose; very large, full in the cup, and very sweet scented.

*Madame Emile-Metz* (Souper & Notting).—Silvery white flower, tinted and shaded with bright rose, centre light carmine, sometimes yellow; very large and full.

*Michael Buehner* (Souper & Notting).—Light brick rose flower shaded with carnation red; very large, full, imbricated, cup-shaped.

*Paul Marot* (Bonnaire).—Pale china rose coloured flower; large, full, very long bud. Cross between *Baronne A. de Rothschild* and *Signor Victor Hugo*.

*Richard Wagner* (Tücke).—Salmony yellow flower, shading off to flesh coloured; very large, full, and sweet. Cross between *Belle Lyon-naise* and *Mary Fitzwilliam*.

*Souvenir de Geneviève Godard* (Godard).—Dark china rose coloured flower; full, large, and sweet.

#### ROSES.—HYBRID PERPETUALS.

*Baronne M. de Lustende* (Pergravand).—Centre of flower dark rose, on the outside bright rose, and lighter shade in the autumn; large, very full, long bud. Cross between *Elizabeth Vigneron* and *Jules Margottin*.

*Claude Jaquet* (Liabaud).—Purplish scarlet flower, lightly shaded; very large, full, convex, and very sweet.

*Climbing Queen of Queens* (W. Paul).—Light rose coloured flower; large and full.

*Duchess of Fife* (Cocker).—Light silvery red; large, full, cup-shaped flower, very sweet.

*Duke of Fife* (Cocker).—Crimsony scarlet flower; full and large.

*Dybowski* (Lévêque).—Clear vermilion red flower; large and full.

*Frances Blowam* (G. Paul).—Brilliant salmony red flower, semi-double.

*Grand Duc Alexis* (Lévêque).—Blood-red flower, shaded with purple and light vermilion, lightened up with bright carmine; large and full.

*Imperatrice Maria Féodorowia* (Lévêque).—Bright rose-coloured flower, clear and bright; large, full, and globular.

*J. Proue* (Lévêque).—Bright red flower; uniform, large, and full.

*Madame Henri Perrin* (Schwartz).—Bright lilac carmine red flower, the petals bordered and shaded with light rose, silvery on the reverse sides; large, full, sweet, the petals in the centre fringed.

*Madame Vignat* (Liabaud).—Light red flower, sometimes bright red; very large, full, and very sweet.

*Souvenir de Poncet* (Pernet).—Light rose coloured flower; large, nearly full, and very sweet.

*Souvenir du Dr. Payen* (Vigneron).—Bright red flower, slightly velvety; large, full, and sweet.

*Spenser* (W. Paul).—Fine glossy red flower, outside petals dark, and white on the reverse sides; very large, very full and compact in shape, opening well.

*Violet Queen* (G. Paul).—Dark crimson flower, shaded with violet; large, full, cup-shaped.—D., Deal.

### AMARYLLISES AT CHELSEA.

INTEREST in the work of Amaryllis improvement as carried on by Messrs. Veitch & Sons at Chelsea appears to deepen rather than diminish as the years roll on. Stage succeeds stage, and yet the climax is not reached. The main attributes held in view by the hybridisers several years ago have nearly all been secured, but still points of advance suggest themselves, and so each succeeding season finds fresh improvements. Considering the beauty and value of the plant, it is not a matter for surprise to find that the attractiveness of the Chelsea collection grows yearly. To the list of visitors who annually inspect it in order to keep pace with the march of improvement are to be added fresh names each year, and these in turn usually come to make a periodical journey to the Amaryllis home.

The present season will perhaps have taken some intending callers a little by surprise. The long spell of warm and genial weather in March, so unusual at this period of the year, brought the plants on with great rapidity, and the consequence is that the bloom is fully a fortnight earlier than usual. Should this intimation catch the eye of any person who is proposing to make a call any time during the next few weeks he or she will not act unwisely if a determination is arrived at to go at once. It will be some time before the collection is quite over, but just now it is quite at its best. It is difficult to avoid indulging in a little retrospection when standing in the Amaryllis house once more and endeavouring to make a comparison between the present and past seasons. The result in the minds of many will probably be a conclusion that for wealth of bloom the present season eclipses all its predecessors. The forest of vigorous spikes appears to have grown thicker, the mass of brilliant flowers seems to have become more dense. Surveying the collection as a whole from an elevated position at the entrance to the house strengthens this impression. Without doubt there is an advance in the floriferousness of the plants. Another point will probably strike regular visitors—the collection as a whole is dwarfer. The plants have not lost an iota of their vigour, the scapes are as stout and strong as they have ever been, but an inch or two have been gained all round, for, within certain limits, dwarfness is an advantage.

The character of the flowers exhibits no marked change. The work has now gone too far for that; development can only be gained slowly. But if we see no great steps made in size of bloom there is a welcome advance in other important qualities. The flowers are becoming more rounded, the segments having lost their old sharpness and having become more evenly disposed. This is giving a far superior type of flower to the old, and may fairly be said to be more important than mere size. It is more difficult to soften the sharpness of the petals than of the sepals, but this object is being steadily achieved. The rounder and the more closely disposed the segments are the more refined and beautiful is the flower, consequently progress in this direction is followed with interest and satisfaction.

Another improvement is the multiplication of self flowers. Tastes differ, of course, but it may be supposed that the great majority of Amaryllis lovers will welcome the elimination of the central rays, especially those of a greenish tinge. If not an absolute disfigurement to the flower they detract in some measure from its beauty, and, moreover, are the sign and token of first principles rather than advanced evolution. The selfs are now the most popular class, and the increase of their numbers adds, and will add, to the merit of the collection. Light flowers, too, are popular, and their beauty, whether lightly or heavily flaked and reticulated, cannot be gainsaid. To sum up the present signs of progress in Amaryllises, the two leading points are roundness of bloom and self colours. The further development of both may be hoped for and expected.

The following comprise twenty-four of the most meritorious novelties of the present year:—Coracle, dwarf, of fine habit, strong and free, rich scarlet; Dolabel, small but very neat, crimson with white rays, free and bright; Mirabella, white, lined and reticulated with rosy red, well rounded, a dwarf sturdy variety; Nyanza, rich crimson scarlet, well rounded, dwarf and good; Cherub, white, regularly lined with rosy red, free and dwarf; Leonidas, scarlet suffused with purple; a large and brilliant flower; Phyllis, white with a few flushes of rosy red, large bloom, dwarf grower; Norma, heavily flaked and reticulated with crimson, dwarf, strong and very free; Pompadour, rich deep crimson, an enormous flower with great breadth of petal; Renown, light red with central bars of white, beautiful shape, well-rounded segments, a strong grower and very free; Calabar, intense crimson with purple

suffusion, dwarf and free; Hecla, purplish crimson with yellowish rays; Ninus, vermilion white rays, segments beautifully rounded and recurved; Leerdan, bright scarlet crimson, fine large well shaped flower; Vedette, rich crimson purple, perhaps the deepest of all, medium size and of good shape; Jocasta, white, crimson bars, a finely rounded flower; Mysis, rich purplish crimson with white rays and flakes, a very large flower of good shape, dwarf and sturdy; Smollett, rich scarlet, very strong and free; Dacca, brilliant but soft shade of red, white rays, good shape; Phormis, deep margin of crimson, centre white, broad sepals and a well rounded flower; Archelaus, glistening crimson self with purple suffusion; Palliser, rich crimson self, purple suffusion; Princess Marie, white with a few flakes, a beautifully moulded flower; and Sardius, almost a self, but with very small central rays, large round flower, and a dwarf strong grower.

The healthy condition of all the plants justifies a few remarks in reference to management. At the time of our visit (March 24th), the plants had only been watered twice since last August, the first time being a month ago, yet they are conspicuous by their fresh appearance, the foliage being substantial and of the richest colour. The Chelsea growers hold that over-watering is one of the commonest evils in Amaryllis culture. Their plants are liberally watered after flowering while making their growth; but after the end of July the supplies are lessened, more air and sun are admitted, and the plants are gradually ripened off. In October they are lifted from the spent tan in which they are plunged and stood upon the stage, receiving not a drop of water throughout the winter. This treatment insures plump and well matured bulbs. Another point of interest in connection with the cultural treatment is the small size of the pots used. They consist of 5 and 6-inch, none larger, and in these enormous bulbs are growing. These matters may be worth consideration on the part of private cultivators, for the results at Chelsea are too strikingly satisfactory to admit of any doubt as to the soundness of the methods pursued.

### DEATH OF MR. JOHN GARRET.

WE regret to announce the death of Mr. John Garret, a respected northern florist, which took place on the 18th March last at 13, Landsdowne Terrace, Gosforth, near Newcastle-on-Tyne. Mr. Garret, who was sixty-nine years of age, was from a very early period of his life an enthusiast in horticultural matters. All through an active business career he lost no opportunity of pursuing his favourite recreation, and made the subject so thoroughly his own that he enjoyed a considerable reputation in the north both as an exhibitor and as an authority. When he retired from business in 1880 he removed to Hindley, near Stocksfield-on-Tyne, and there his tastes obtained full scope. His garden soon became known as one of the horticultural treats of the neighbourhood, and he always welcomed anyone interested in plant culture.

While at Hindley Mr. Garret enhanced his reputation as a successful exhibitor. His principal successes were in Begonias and Zonal Pelargoniums. These he brought to a remarkable perfection, and with them was repeatedly first at the Newcastle shows. The expiry of his lease compelled him to leave Hindley, and he took up his residence at Gosforth. There his opportunities for floriculture were very limited, but he retained his interest in it till the last. He subscribed to the first number of the *Cottage Gardener*, and took considerable pride in his well bound set of it, and its continuation volumes of the *Journal of Horticulture*, and to the diligent study of their pages he attributed much of his proficiency in the art of plant culture. Several years ago, when one of the staff of this paper was in the north, Mr. Garret learned that he was one of six who were known to have been among the original subscribers. He often alluded with gratification to this fact.

Mr. Garret took an active part in encouraging horticulture, and was an enthusiastic supporter of the Newcastle Botanical Society. For a long period he was a member of the Committee of that body, for some time occupying the position of Vice-Chairman. At the time of his death he was the only honorary life member of the Society, a mark of distinction conferred upon him in recognition of his disinterested and unwearied services to the cause in the North of England.

### GARDENERS' ASSOCIATIONS AND SITUATIONS.

I WAS more than pleased to read the outspoken remarks, under this heading, of your correspondent "A., Yorks," in a recent issue (page 173), as he gives expression to views that I have long held myself. If the Royal Horticultural Society, which is looked upon as the exponent of practical horticulture in this country, could be prevailed upon (in addition to its other work) to inaugurate a "National Registry," where employers might seek and find good gardeners, I believe (with your correspondent) the Society would get a much larger share of the gardeners' support than at present, and employers might also be expected to associate themselves with the Society.

The "National Registry" could be "worked" well with the Society's examination scheme. Of course the "Registry" would not be confined to those only who presented themselves at the examinations. It would be open to all who chose to avail themselves of it. Would it not be an incentive to an employer to engage a man who had passed successfully through these examinations (not, by any means, that these will cause all the good men to come forward)? which, let us hope, will tend towards a considerable thinning out, to use a gardening term, of so-called gardeners in the ranks; this latter class causing the over-supply we must all deplore to see at the present day, and acting most prejudicially in the all-important matter of remuneration to really good men.

The question of wages, although a tender one to touch upon, is not one by any means to be despised, and doubtless the scanty pay of gardeners (of course there are notable exceptions, but these only serve to prove the rule) very effectually deters many an intelligent young man—one who wants to make way in the world, and is desirous of entering the profession—from taking the step.

Let us make the gardener's calling one well worthy to be embraced, attracting to it fit representatives, adequately recompensing the men who assist Nature in producing the useful as well as beautiful results to be witnessed on every side, and there will be no lack of "good men and true" forthcoming, men who will shed lustre on the "gentle art." I should much like to see this very important matter thoroughly discussed. It is one right worthy of such prominence being accorded.—J. B.

### SPIRÆAS.

SOME of the most popular of the Spiræas are unrivalled for general decorative purposes, and being so easily forced they can be had in bloom from Christmas to April and May. When grown in pots abundance of water must be applied to bring these plants to perfection. Liquid manure, such as drainings from the cowsheds, is an excellent stimulant for Spiræas, and should be applied two or three times a week after the flower spikes begin to show. I find the best results are obtained by filling a bucket or tub with about one part of liquid to two of clear water, and dipping the plants so that the water comes over the top of the pot and letting them remain till the soil is thoroughly moistened. Care should be taken not to wet the foliage, otherwise it will present a stained and dirty appearance.

The old *S. japonica* is too well known to need any comment here, other than saying that it is the best of the whole genus for early work, for when well ripened clumps are procured and potted early in the autumn they will stand hard forcing. *Spiræa astilboides* is a useful plant. The stems grow from 2 to 3 feet in height, forming a pretty bush, above which elegant white flowers are produced. It does not force so readily as *S. japonica*, for if subjected to too high a temperature it is liable to become drawn.

*S. Aruncus* (the Goat's Beard) possesses sufficient attractions to secure its admission into every well kept garden. It grows to a height of from 4 to 5 feet. The long feathery plumes are most graceful. It prefers a moist shady position, being most effective as a background to herbaceous borders and in sheltered corners of the pleasure grounds.—G. PARRANT, *Ashby Lodge Gardens, Rugby.*

### JOTTINGS FROM MEMORY.

IN Mr. J. W. Moorman's interesting article under the heading of "Jottings from Memory" (page 217) reference is made to the growth and hardiness of *Fabiana imbricata*, the Myrtle, and *Aloysia citriodora* at Teignmouth, Devon. This reminds me of other places where I have seen the above mentioned popular shrubby plants flourishing.

*Fabiana imbricata* growing against the south front of the Bishop of Salisbury's palace, Salisbury, yields a profusion of its pure white long-tubed, Heath-like flowers, in May and June every year. This shrub, introduced in 1838, is not so frequently met with in southern and western counties in England and Ireland as it undoubtedly deserves to be, giving it the protection of south wall and light peaty soil to grow in being all the attention it requires, excepting the training and securing of young growths to trellis or wall. I have seen huge bushes of the Myrtle in the grounds of Appley House, Ryde, and, I believe, at Binstead, near the same fashionable watering place, also at Osborne and other places in the Isle of Wight.

The finest plants of *Aloysia citriodora* that I have seen growing out of doors were at Mr. Dadd's, North Devon Fernery, Ilfracombe, growing and trained against the south wall of his dwelling house. Another occupying a like position on the house of C. S. South, Esq., The Close, Salisbury; and one trained against the coachman's house, Emo Park, Portarlinton, Ireland, covered a good space of wall. At Frogna, Fooks Cray, Kent, there used to be, and perhaps are still, two fine plants (bush plants) growing on either side the steps descending to the flower garden from the conservatory. These used to be tied into pyramidal form on the approach of severe weather, and fern wrapped round them and neatly trimmed, first lay on about 6 inches deep of ashes over the roots, thus making the plants quite secure during the winter months. With me the roots are protected in the manner indicated, the branches being killed down to the ground in severe winters, but they push into fine growth from the base in due time every season.—H. W. WARD.

CIRRHOPE TALUM PICTURATUM.

ABOUT thirty species of *Cirrhopetalum* are known, but very few of these are in general cultivation. Like their near allies the *Bulbophyllums*, they are remarkable rather for the peculiarity than

the beauty of their flowers. *C. picturatum* (fig. 50) is, however, attractive alike in form and colour, and no doubt requires only to be better known to become popular. It is a dwarf free-growing species with ovoid pseudo-bulbs, each bearing one dark green, oblong, fleshy leaf from 3 to 6 inches in length. The scape,

FIG. 50.—CIRRHOPE TALUM PICTURATUM.

which is produced from the base of the pseudo-bulb, is about 8 inches long. The flowers are borne in a semicircular umbel, and the inflorescence has a somewhat curious appearance. The small upper sepal is green, spotted with red, and has an awn-like filament at the apex. The lateral sepals are about 2 inches in length; they are united by their margins, and form one long blade of an emerald green colour. The lip is very small, almost black, and conspicuous only by its vibration with the slightest breath. The prolongation of the lateral sepals is characteristic of the genus, and distinguishes it from the *Bulbophyllums*.

Abundance of light, air, and water are the chief factors in the successful culture of this plant. It succeeds equally well in baskets or on blocks suspended near the roof in a warm house. *C. picturatum* is said to have been grown in London fifty years ago, but it had apparently disappeared from cultivation until re-introduced from Moulmein a few years since.—A. B.

## ORCHIDS AT ST. ALBANS.

ONCIDIUM AMPLIATUM MAJUS makes a unique display of flower here just now, there being many spikes of bloom of this old favourite, the individual spikes carrying upwards of 200 blossoms. The floral effect is enhanced by the peculiarity of the bright yellow flowers being of a milky whiteness on the under side. Dendrobium hybridum Owenianum is a good companion to the lovely and brilliant D. Venus and the graceful D. Cassiope. It was raised by Norman C. Cookson, Esq., Oakwood, Wylam-on-Tyne. The flowers, which are produced with the greatest freedom, are borne in twos and threes, being carried well away from the pseudo-bulbs.—J. B.

## DENDROBIUM NOBILE.

AT the present time there is to be seen at the seat of J. P. Brice, Esq., Bystock, Exmouth, S. Devon, a grand specimen of Dendrobium nobile in bloom. The plant is between 4 and 5 feet in diameter, and bearing from 500 to 600 fully expanded flowers. Mr. Swan lays great stress on the ripening and resting of Dendrobiums, which proves beyond a doubt that this treatment is correct by the lovely specimen to which I have alluded. There will be a grand display for some time to come, as some plants are just starting and others are showing their buds.—D. H. M.

## ANGRÆCUM SANDERIANUM.

A specimen of this charming little Angræcum, certainly the best of the smaller species, is now flowering in the warm Orchid house at Kew. It is a native of the Comoro Islands, and was introduced by Mr. Sander of St. Albans, whom it commemorates. It is of very dwarf habit, with shining dark green tongue-shaped leaves from 3 to 6 inches in length. The flowers are borne in two rows on a graceful drooping spike about 1 foot long. They are about 2 inches in diameter, of the purest white, and last a long time. The spur is 3 or 4 inches in length. If treated like Phalænopsis no difficulty is experienced in keeping this species in perfect health. It is well figured in vol. xxi., page 489, of this *Journal*.

## CALANTHE STRIATA.

THOUGH the evergreen species of Calanthe do not enjoy the widespread popularity of the more showy deciduous sorts, amongst them may be found plants of decided merit. *C. veratrifolia*, *C. masuca*, *C. furcata*, and *C. striata* for instance are free flowering and handsome species that would grace any collection. The last-named, as represented by plants now in flower at Kew, has erect racemes about 15 inches high, with flowers about 1½ inch in diameter. The sepals and petals are cinnamon-brown with a narrow margin of golden yellow; the three-partite lip is pale yellow. The dark green lanceolate leaves are about 9 inches in length. *C. striata* is a native of Japan. It requires an intermediate temperature, and succeeds well in a compost of peat and loam with a little silver sand and sphagnum added. Plenty of moisture at all times is essential.—A. B.

## HORTICULTURAL EXAMINATIONS.

THE Royal Horticultural Society, in compliance with numerous requests from county councils, directors of technical institutes, lecturers, and others, intends to hold an examination in the elementary principles and in the practice of horticulture. The date fixed for the examination is Thursday, May 4th.

Being anxious that everyone in the United Kingdom who desires to sit for such examination may have the opportunity of so doing without unreasonable difficulty, we are prepared to institute such examination in any village or town in the kingdom where any magistrate, or clergyman, or schoolmaster, or other responsible person accustomed to the conduct of examinations, will undertake to act as our representative and see that our rules are strictly observed, and that no copying or consulting of books, &c., takes place. Anyone, therefore, wishing to sit for such examination can do so close to his own house, if he will, by the end of the first week in April, put me in communication with any such responsible person who is willing to act as our supervisor of the examination. Obviously we must leave this part of the work to the candidates themselves, as we cannot know the names of suitable and willing persons in every village and town in the country.

Three scholarships of £26 a year, tenable for two years, are offered in connection with the examination, and I am already in correspondence with a very large number of persons in all parts of the country with reference to it.

A fee of 3s., payable in advance, will be charged to all persons entering for the examination, and all letters on the subject requiring an answer should contain a stamped and directed envelope. I need

hardly say that the fee of 3s. will not nearly cover the necessary expense of the examination, which will, therefore, entail considerable loss on the Society's general funds; but the Council are of opinion that by putting the fee as low as possible they are promoting the best interests of horticulture, and they trust that their action will commend itself to all lovers of gardens. The entrance fee should in all cases be sent to me before the date of examination.—W. WILKS, *Secretary, Royal Horticultural Society, 117, Victoria Street, S.W.*

EVENTS OF THE WEEK.—Apart from the customary auction sales, but little of horticultural interest will take place in the metropolis during the ensuing week. The monthly meeting of the National Amateur Gardeners' Association will be held, however, on Tuesday, April 4th, at the Memorial Hall, Farringdon Street, and the Fellows of the Linnean Society meet on Thursday, April 6th.

— THE WEATHER IN LONDON.—We have to record another week of bright dry weather in the metropolis. Saturday and Sunday were warm and sunny, but cold winds were prevalent on Monday. Tuesday was also a typical March day—bright, with rather keen winds. Wednesday opened similarly, and at the time of going to press there are prospects of the fine weather continuing.

— WEATHER IN THE NORTH.—We have had a week of remarkably fine weather, the days sunny and warm, with frosts of from 4° to 6° during the nights. Although there has been no frost for the last two nights (28th), the weather has been colder, as the wind set into the east on Sunday.—B. D., *S. Perthshire*.

— BRITISH FRUIT GROWERS' ASSOCIATION.—A general meeting of the members of this Association was held at the Hotel Windsor on Tuesday, March 28th, Mr. T. Francis Rivers occupying the chair. Owing to the gross irregularities of an official it was ultimately, on the proposition of Mr. Jefferies, seconded by Mr. Bunyard, unanimously resolved "that the affairs of the Association be forthwith wound up with a view to its dissolution." A sub-committee was appointed to carry out the necessary details relative to the proposition.

— DEATH OF MR. ALEXANDER MCKENZIE.—We regret to announce the death of the Bailiff of Epping Forest in his sixty-fourth year. Mr. McKenzie was born in Inverness-shire, and eventually became gardener to a member of the Metropolitan Board of Works, and his abilities recommended him to other and wider duties. He designed the grounds and planting of the Alexandra Park, also the Thames Embankment Gardens, and planted the avenue of Plane trees along the fine promenade. He was also employed in landscape work generally till his appointment by the Corporation of London to the position which he creditably occupied till his death. Mr. McKenzie was a Major of the Honourable Artillery Company, and was greatly respected by many friends. His funeral takes place in the Finchley Cemetery at 2.30 on our date of publication.

— DAISIES FROM SEED.—Those who wish to work up a stock of these useful spring flowering plants quickly will do well to give this method of propagation a trial, for if they obtain seed from a reliable firm they may depend upon getting a large percentage of really good flowers. Last June I sowed some seed, and when the seedlings were large enough planted them in rich light soil 6 inches apart, taking care throughout the summer months to keep the soil well stirred with the hoe. With this treatment they grew strong and sturdy, showing much greater vigour than other plants obtained by division. The seedlings are now coming into flower, the few worthless ones being consigned to the rubbish heap, and the others are planted in beds and borders. I find the white and pink forms are especially good, the flowers being large, full, and equal to many named varieties. Daisies of all descriptions do best with us when the planting is delayed till spring, for however firmly the soil may be pressed around them, if removed during the autumn, the action of the winter frosts upon the soil loosens it so much that many of the plants are lost in consequence of the roots being exposed to sharp frosts when unaccompanied by snow.—H. DUNKIN.

— GARDENING APPOINTMENT.—Mr. John Southwell, late under gardener at Berkswell Hall, has been appointed head gardener to C. W. Digby, Esq., Meriden Hall, near Coventry.

— DEATH OF MR. HENRY DEVERILL.—We regret to hear of the death of Mr. Henry Deverill, the well-known seedsman, who died on the 16th inst. at his residence, Grimsbury, Banbury. Mr. Deverill, who had a wide reputation for his "pedigree" Onions, was in his fifty-second year, and leaves a widow.

— SENEIO SAGITTIFOLIUS.—This new species, which was introduced from Uruguay, is now flowering in the succulent house at Kew for the first time in England. The flowers are white with yellow disc, and are produced in heads on spikes several feet in length. The leaves are dark green and attain a length of nearly 3 feet.

— WAKEFIELD PAXTON SOCIETY.—At a meeting of the members of the above Society Mr. A. Batty of Rothwell read a paper on "Legends Respecting Trees and Plants." The essayist gave much information with regard to a large number of trees and plants, and some curious and amusing legends connected with them.

— LEE, BLACKHEATH, AND LEWISHAM HORTICULTURAL SOCIETY.—The subject of a paper by Mr. J. Laing was "Begonias and their Culture," read before a good attendance last Friday evening. A first-class certificate was awarded to Mr. Judge, gardener to J. C. Geiselsbrecht, Esq., Lee, for a seedling Clivia of two trusses, containing seventy-six blooms of a deep orange colour.

— DEATH OF MR. W. TRESEDER.—We regret to announce the death of Mr. Wm. Treseder, the well-known florist and nurseryman of Cardiff, which occurred somewhat suddenly at his residence in Cowbridge Road on Wednesday, 22nd. Mr. Treseder was in his sixty-fourth year, and had not only the establishment in Cowbridge Road, but he had also established a large nursery at Llandaff, and extensive gardens at Whitechurch. Mr. Treseder was a member of the Canton Local Board, and when that district became merged in the Cardiff Corporation he was twice elected to the Council for the Canton Ward. The business will be carried on by Mrs. Treseder and the sons. The funeral took place on Monday at Llandaff Cathedral.

— SPRAYING FRUIT TREES.—A law has been enacted in Ontario, Canada, forbidding the spraying or sprinkling of fruit trees while they are in bloom with any mixture containing Paris green or other substances poisonous or injurious to bees. The object of the legislation is to protect the bees from harm, the honey from possible taint of poisoning, and to avoid obstacles to the complete fertilisation of the fruit.

— EXPORTATIONS OF POTATOES.—It may seem curious to the ordinary public to note that while salesmen are importing thousands of bushels of Potatoes into this country from France, Germany, and elsewhere, home growers are exporting tubers to America. A transatlantic contemporary to hand states that on one day early in the current month no less than 31,883 sacks of Potatoes were received from Dundee, 175 sacks from Liverpool, and 1736 sacks from London.

— BIRDS AND FRUIT BUDS.—Mr. James Hiam, Astwood Bank, writes:—"Readers will see on page 223 that 'W. T.' and I do not agree about poor 'Chit-a-dee-dec,' a local name for the tits. It may not be the first time we have had a good humoured 'peck' on another matter, and if so we are quite as likely to retain our own opinions in this question. Unless 'W. T.' can suggest a better plan than mine—viz., to carefully watch every movement of these birds for forty or fifty years, and then shoot one when feeding on fruit trees among the buds to clear up a disputed point, open its craw and gizzard, turn out the contents, and save it for future contradictions should they arise, and find nothing but injurious insect pests instead of buds; why, I must leave the matter as it stands."

— ALLOTMENTS AT HAMPTON WICK.—The Board of Works having, after much trouble, finally permitted the Local Board of Hampton Wick to have possession of six acres of meadow land lying between the Thames and the Home Park, near Kingston Bridge, the ground was marked out in 10 rod and 20 rod plots, and balloted for last week, and possession taken by the allotment holders on Saturday last. The soil is of dark free nature surfaced by a rich pasture, and should with due cultivation make fine garden ground. The first efforts at breaking up were not encouraging, as many of the holders seemed to have poor notion of digging, and did their work in an indifferent and laborious way. The ground was originally priced at 1s. per rod, but the applicants rebelling the Local Board reduced it to 6d. per rod.

— DEATH OF DR. KARL PRANTL.—The "Botanisches Centralblatt" announces the death of Dr. Karl Prantl, Professor of Botany in the University of Breslau, and Director of the Botanic Garden there. For some years past Dr. Prantl has edited "Hedwigia," a journal devoted to cryptogamic botany; but it was chiefly as a teacher that he was known.

— NEW PLANTS FOR 1892.—A list of the new plants for 1892 has been published as an appendix to the *Kew Bulletin*. The list, however, not only includes new plants, but those that were re-introduced last year after being for some time lost to cultivation. Brief descriptions of the plants are given, as also are references where they have been fully described or figured.

— SULPHATE OF AMMONIA FOR FORCED STRAWBERRIES.—It may not be generally known that sulphate of ammonia is an excellent stimulant for Strawberries in pots. Given once a week at the rate of half an ounce to 1 gallon of clear water is a safe plan of using this powerful stimulant, and does not interfere with the regular supplies of liquid manure usually employed for this purpose.—S.

— THE HERTFORD HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.—This Society, which has been in existence only fifteen months, is in a most flourishing condition, and has a membership of 240. Exhibitions amongst members are held fortnightly, certificates of merit being awarded to the professional gardeners, amateurs, and cottagers' sections for the best exhibits of fruit, flowers, or vegetables. The Chrysanthemum Show in connection with the Society is fixed for November 2nd and 3rd, 1893.

— WE have received several parts of the French edition of Nicholson's "Illustrated Dictionary of Gardening," which is appearing under the title, "Dictionnaire Pratique d'Horticulture et de Jardinage." It is under the editorship of M. S. Mottet, assisted by MM. Vilmorin Andrieux et Cie., G. Alluard, E. André, G. Bellair, and G. Legros. With such a staff at his command M. Mottet may well undertake such a task, and with the examples before us we look forward to the production of such a work as will be of great value when completed.

— DESTROYING INSECTS.—In his paper on Plant Culture and Insect Pests, read at a meeting of the Liverpool Horticultural Association, Mr. Hugh Ranger recommended for mealy bug either Fir tree oil or petroleum, the latter being used at the rate of a wineglassful to three gallons of water. For thrips he had not found anything better than tobacco smoke. For aphids or green fly quassia chips and softsoap. For red spider he recommended a moist atmosphere, by having the hot-water pipes coated thickly with sulphur, taking care to put plenty in the troughs as well, then heating the pipes to nearly boiling point and keeping the house closed for a few hours.

— MOSELEY BOTANIC GARDENS, BIRMINGHAM.—We have received a schedule of prizes offered at the exhibitions to be held at the above gardens during the ensuing summer. On May 10th and 11th an exhibition of floral designs, bouquets and similar decorations will be held, while on June 7th and 8th there is to be a special display of Pelargoniums, Orchids, Pansies, and stove and greenhouse plants. A great Rose show will be held on July 19th and 20th, and on August 29th, 30th, and 31st there is to be an exhibition of Dahlias and other flowers, fruits, and vegetables. Mr. W. Dean, Dolphin Road, Sparkhill, Birmingham, is the manager of the exhibitions.

— PROPOSED TESTIMONIAL TO MR. M'HATTIE.—The removal of Mr. J. W. M'Hattie from the gardens at Newbattle Abbey to an important position in the south of England has been considered by a number of his brother horticulturists and personal friends a fitting opportunity to express in a tangible form the high esteem in which he is held. Mr. M'Hattie has occupied the position of gardener to the Most Noble the Marquis of Lothian at Newbattle Abbey for the period of eight years, and by his rectitude of character, intelligence, courtesy, and kindness of manner, has endeared himself to all with whom he has come in contact, whilst his success as a cultivator in many departments of horticulture, notably as an exhibitor of fruit and Chrysanthemums, as well as his valuable contributions to horticultural literature, entitle him to a prominent place in the front rank of Scottish gardeners. A Committee has been formed to receive subscriptions for the purpose of presenting Mr. M'Hattie with a testimonial previous to his leaving Scotland, and the time available being very limited, all who wish to subscribe are invited to intimate their contributions to any member of Committee, or direct to the Secretary or Treasurer, not later than Saturday the 1st of April.—MALCOLM DUNN, *Chairman of Committee, The Palace Gardens, Dalkeith.*

— **CULTIVATION OF PLUMS.**—In connection with the series of lectures on "Hardy Fruits," under the auspices of the Scottish Horticultural Association, Mr. Dunn, Dalkeith, recently delivered a lecture on "Plums." Mr. Dunn remarked that even the Apple, from a commercial point of view, was very little more important than the Plum. For private purposes the Plum was most valuable, as it could easily be preserved. The merits and qualities of the different varieties, both in Scotland and England, were touched on, and the means of raising new varieties discussed.

— **FRUIT AND POTATO TRADERS' BENEVOLENT SOCIETY.**—Many members of the wholesale fruit and Potato trades and growers met at the Holborn Restaurant on the 22nd inst., to inaugurate the first festival dinner of a new charity called the London Wholesale Fruit and Potato Trades and Growers' Benevolent Society. The Lord Mayor presided, and there was a large attendance. The object of the Society is to provide pensions and homes for the necessitous salesmen and growers. The annual subscription is one guinea, entitling a subscriber to one vote; five guineas covers a life governorship and two votes. The age for pensions has been fixed at fifty-five years, and will not exceed 15s. per week to men, and 10s. to widows. A sum of £600 was received in connection with the dinner.

— **GRAPES AT FLOORS.**—Mr. J. H. Goodacre writes:—"Mr. Barnes (page 239) will not expect all to smile on the plan he adopts in calling his own mistakes other people's errors. It may be news to Mr. Barnes to hear that I know too much of Floors to suppose the Vines that produced the Grapes figured on page 31 of this Journal to be forty years old. As the variety has not been raised quite forty years yet I should not be guilty of committing this 'error.' Mr. Barnes takes pains to describe much of the important work done at Floors during his few years' service there, but does not appear so anxious to give credit to the present managers." Another correspondent sends us extracts from his diary having reference to the lifting of Vines and the renewal of the border there, but it is scarcely necessary to prolong the discussion on those points. The condition of the Vines sufficiently indicate that the work was done well, and the Grapes we have seen were highly creditable to the cultural skill of both the present gardener at Floors and his predecessor.

— **MARCH WEATHER IN HAMPSHIRE.**—What a contrast is the weather experienced throughout the present month as compared with that of the same month for the past two years. The temperature registered to-day (25th) here was 71° in the shade, yesterday 70°. On nine days previously during the month 60° and over were registered. Throughout the whole of the corresponding month of last year the thermometer rose but four times past 60°, 64° being the highest point gained. During the year 1891 but twice did we register 60°, and that on the 1st and 2nd of the month, 58° being the highest point attained besides. In the matter of moisture this month compares favourably so far with the last. The first three days rain fell to the extent of 0.35 inch, since that date we have not had to record a single drop. If there is any truth in the saying that March dust is worth a guinea an ounce we ought to be favoured this year in point of weather, as hereabouts there is plenty. Many of the nights have really been warm, on several occasions the minimum register not being lower than 45°.—E. MOLYNEUX, *Swanmore Park*.

— **INSTRUCTION IN HORTICULTURE.**—During the past three weeks, Mr. James Hiam, Astwood Bank, has carried out, in connection with the Worcestershire County Council, most successfully eighteen meetings in classes in practical work, such as pruning, grafting, budding, grease-banding illustrated, insecticides, and their distribution. At twelve meetings three powerful microscopes have been busily employed in making the classes and public practically acquainted with insect pests to fruit growers, such as red spider in the egg and at maturity, the effects of their destructiveness on Gooseberry bushes; the winter moths, their eggs as found on trees and hatched out, and the caterpillars crawling by hundreds; the Black Currant mites and the infested buds; Plum aphid as found in winter, and the young produced by the viviparous females; Apple aphid in the egg state and hatched out; Psylla mali in the eggs and hatched now on the trees; mussel scale; brown scale, and others well known by sight but not by name. These subjects have been explained as each came under observation, and the best known remedies to counteract them. The series of lectures will conclude with birds and horticulture; innocent useful insectivorous birds; partially so; and destructive birds, and how best to deal with them.

— **DEATH OF DR. G. VASEY.**—We learn from "Nature" of the death, on the 7th instant, of Dr. G. Vasey, the chief of the botanical section of the United States Department of Agriculture at Washington. He was a native of Yorkshire, we believe, and emigrated to America many years ago. The Grasses of North America were his special study, and he published several important works on this family. The "Grasses of the Pacific Slope" and the "Grasses of the South-West," fully illustrated, are his latest works; but the former is not yet completed. Dr. Vasey wrote also on the agricultural value of the Grasses of the United States. Last year he visited England, and made many friends through his amiable disposition.

— **THE NATIONAL AURICULA SHOW.**—Those interested in the cultivation of this favourite plant will have an opportunity on April 25th, at the Drill Hall, Westminster, of seeing a display, principally by amateur growers, of Auriculas and other spring flowers. Of late years many new and beautiful varieties of the former old florists' flower have been obtained by judicious crossing and careful cultivation, while some of the older kinds of Auriculas, which were grown by our forefathers, are still to be found in many collections. Being an amateur grower in a small way of this floral pet, the Auricula, I wish to bring under the notice of those who have not yet cultivated it what little space and small outlay is required, a cold frame only being necessary to protect the plants in severe weather. At this forthcoming show a liberal prize list will be offered for competition. The show promises to be a very good one owing to the favourable season, and some of the leading northern growers are likely to exhibit. Prizes are also offered for seedlings, and many good ones may be expected. I have always found growers of the Auricula at these annual gatherings ready to impart information and give useful hints to less experienced cultivators.—W. SMITH *The Links, Bishop's Stortford*.

— **SOWBREAD AND SWINE'S SNOUT.**—On page 230 I observe that a correspondent objects to these undignified and inelegant names as applied to the Cyclamen and the Sisyrinchium respectively. As for the first it is founded upon fact, and I believe originated in the Italian language, as it is said that in Italy, and especially in Sicily, wild swine feed largely on the roots of the Cyclamen which abounds there. The name passed on to us through France, where the bulb is known as *Pain de Pourceau*. But the name Swine's Snout, besides being objectionable in itself, originated in an utter misconception of the meaning of the Greek name Sisyrinchium. I am not going to discuss the hopeless subject of the identity of the plant which Theophrastus calls Sisyrinchium. It was a white bulb, classed by that writer amongst wool-bearing (eriophorous) bulbs, of which the soft fibrous substance of the tunics was utilised, and even supplied material for worsted stockings. There is some doubt amongst editors about the right spelling of the name, both in Greek and Latin; but the Greek word *sisyra* and its diminutive *sisyrinium* bear the sense of a woolly or shaggy cloak. It is probable that these words are connected with the name of the wool-bearing bulb. No Greek author could have made such a clumsy compound of the two words suos + rhynchos (Swine's Snout). The similarity of sound is quite accidental.—C. WOLLEY DOD, *Edge Hall, Malpas*.

— **WIDCOMBE HORTICULTURAL CLUB.**—A meeting of this Club was held on Tuesday night in Widcombe Parish Room, Mr. B. J. Baker presiding over a numerous attendance of members. Mr. F. Nash's paper on "Bulb Culture" was read by Mr. R. A. Moger, the Honorary Secretary, and proved to be of much practical value. Mr. Nash had previously given a lecture on the same subject, and now he dealt with the various forms of Lily and Iris. Lilies, he explained, were matchless for providing cut flowers, giving a supply from May until autumnal frosts set in. Borders of Rhododendrons and Azaleas were most suitable for Lilies, and they also flourished among herbaceous plants and in the shelter of trees, while rockeries and artificial mounds suited some varieties, or they could be grown in any ordinary border where leaf mould could be obtained in quantity. Speaking of different kinds, Mr. Nash alluded particularly to *Lilium auratum*, and, referring to *L. giganteum*, said the only specimen he knew of in the neighbourhood was in the Royal Victoria Park. The Iris is evidently a great favourite with Mr. Nash, who said it was invaluable as a cut flower, competing in richness and variety of colouring with the most beautiful Orchids. There were upwards of 200 varieties, and when the whole collection was put together it formed a group unparalleled in beauty, for on one bloom might be found from twelve to twenty different shades all harmonising. They would thrive anywhere where they could get sufficient moisture. A cordial vote of thanks was passed to Mr. Nash for his paper.—(*Bath Journal*.)

— TOMATOES FOR PROFIT.—I can assure "Nemo" (page 234) that Tomatoes will pay in a house the size he mentions, and for summer growth he will want no fire heat, if he has other convenience for raising his plants. Plant them out in good loam 2 feet apart alternately, and train upright to stakes; pinch all side shoots, but leave the main leaves intact. Very little manure will be needed, but a dusting of soot occasionally will give tone to the foliage, as well as help to keep down the white fly. The best stimulant I ever tried for Tomatoes was fish manure; a sprinkling twice when swelling their fruit is ample. If there is sale for cut flowers in autumn, why not have Chrysanthemums planted out in the open ground to lift, and bring in the house after the Tomatoes are over?—T. ROGERS, *Melton Hill Gardens, Brough, E. Yorks.*

— THE WEATHER IN THE MIDLANDS.—The weather here during the last fortnight has been exceptional for the time of the year, very bright, and frequently quite hot in the sun, with the result that vegetation is more forward than I ever recollect it in March. Nights have, however, been cold; nearly 7° of frost on the morning of the 19th, and lighter frosts on many other mornings. Pear bloom on my south wall opened March 24th. I have, during twenty years' record, only one previous for March, while in two years it has been May 1st, and the average the first to the second weeks in April. The bloom is also more regular. Doyenné du Comice, usually a week or so later than Beurré Diel and other earlier bloomers, opened on the 26th inst. The bright weather is most enjoyable, and the bloom looks very healthy; but I

FIG. 51.—CALADIUM SOUVENIR DE PARO.

— BECKENHAM HORTICULTURAL SOCIETY.—The second of the present course of lectures being delivered before the members of this Society was given on Friday last to a large and deeply interested audience, the subject being the Tomato, and the lecturer Mr. A. Dean, who, so far as time would permit, covered wide ground in relation to indoor and outdoor culture, sorts, soils and training. Dr. Kirby presided, and referred to his early acquaintance with the Tomato in the island of Corfu, where forty-five years ago it was largely grown, also to the success which had attended his own gardener's efforts to supply him with Tomatoes up to February by sowing seed late, pushing the plants on to set fruit in the autumn, and ripening them in heat later. Some beautiful cut Tea Roses, Catherine Mermet, The Bride, and Ami Hoste were shown by Mr. Crosswell, gardener to W. H. Bullivant, Esq.; capital Amaryllises by Mr. Beech, gardener to R. Stevens, Esq.; and a charming bunch of Staphylea colchica from Mr. Webster, gardener to Dr. Kirby. Cordial votes of thanks were awarded.

fear the future. Last year the first Pear bloom did not open till April 10th, fortunately, as severe frosts and terribly cold winds followed, checking and saving the later blooms.—F. M. M., *Edgbaston.*

#### CALADIUM SOUVENIR DE PARO.

For general decorative purposes dwarf Caladiums are undoubtedly more useful than those which attain a height of 2 or 3 feet, and in most gardens are in great request. The variety depicted in the illustration (fig. 51) is of this type, for it rarely exceeds a height of 1 foot. It is, moreover, of an attractive appearance, and when exhibited by Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea, at the Drill Hall on May 3rd last year, the Floral Committee of the Royal Horticultural Society awarded it a first-class certificate. The leaves are comparatively large, deep red, with broad green margins slightly marked with yellow, and red veins. It is worthy of place in every collection.

## MR. SHEA AND MR. GORDON.

It is not my intention to take any part in the discussion on the proceedings in connection with the recent election of the Chairman of Floral Committee of the National Chrysanthemum Society, but I must protest in the strongest possible manner against the implication running through Mr. Shea's letter that I have been associated with the dissensions and squabbles in the Society which have been discussed in your pages. I greatly regret that Mr. Shea should have thought proper to attempt to discredit me by innuendo, for which there has not been the slightest justification, or indeed anything that could be so construed. —GEORGE GORDON.

## MR. DEAN AND THE N.C.S.

It is rumoured that Mr. Richard Dean is contemplating his resignation of the secretaryship of the N.C.S., because his indiscreet action on behalf of Mr. Shea's election as Chairman of the Floral Committee has been disapproved by this gentleman. We have also heard that the alleged intention, if carried out, may lead to some withdrawals of members. If this occur the cause will be apparent. We are not alone in thinking that Mr. Dean's mistake as a paid official in attempting to influence the election of Chairman in a private way would be small in comparison with the greater error he would commit by allowing himself to be the author of disruption. He is a very able man and an excellent Secretary when he confines himself to carrying out the wishes of a Committee which undoubtedly he did not do in the case referred to. The Society would, no doubt, survive his withdrawal, though it may not have made quite so much progress as his last Report implies.

POSSIBLY this last whip of the Secretary will be the means of putting things right, as it affects those who are on the Committee, and they will perhaps have a little sympathy for others. I think a National Society should certainly have a Secretary who will place all letters that are addressed to him for the Committee before that body; also one who will not send private letters to influence votes against any committeeman. —W. WELLS, *Earlswood*.

THE N.C.S. COMMITTEE *versus* GODFREY AND OTHERS.

THE thanks of Chrysanthemum growers are due to the Editor of the *Journal of Horticulture* for the fair and unprejudiced publicity he has given to the recent discreditable proceedings connected with the Committee of N.C.S., and I fear Mr. Shea is in error when he suggests that readers are becoming tired of the discussion. At any rate, it is not the case with those with whom I have come in contact, and few will consider the case honourably settled till a more satisfactory explanation is forthcoming. The awarding of certificates to new varieties of Chrysanthemums is of such importance to growers and exhibitors that members of the Floral Committee should be above a suspicion of partiality.

I should like to see more of our best growers—as Messrs. Molyneux, W. Drover, G. Drover, Flight, and many others—occasionally elected; we should then probably have fewer inferior varieties certificated annually to be sold at fancy prices, and after a year or two's careful growing consigned to the rubbish heap. In my opinion, certificates ought not to be awarded to new varieties till blooms can be shown in form and size equal, if not superior, to those already in commerce.

The N.C.S., it appears, has gained strength by the recent controversy, and if a better state of affairs can be brought about by the publicity given to what most people will consider highly discreditable proceedings, Chrysanthemum growers will, I am sure, tender their best thanks to the *Journal of Horticulture*. —G. TRINDER, *Dogmersfield Gardens, Winchester*.

## JUDGING CUT BLOOMS.

MR. LAMBERT (page 240) misses the point of my objection to the method of judging stands of cut blooms by comparison. Were I certain that every bloom in stand A would be pitted against the same variety in stand B I should advocate the comparison method; but my argument is that never do two stands come in opposition containing the same varieties, and certainly never in the same order of arrangement to admit of their being compared readily. Where I hold that method of judging to be wrong is when one variety is pitted against another and at the same time the former is represented in both stands, but in such a position as to receive an injustice through being compelled to compete against a variety possessing points of merit not obtainable in the best grown bloom possible of the first named.

Adjudicating by an agreed code of points dispenses with haphazard arrangement of any particular variety. Every bloom is appraised on its individual merits, and recorded clearly for future reference, if necessary. It is not so in "comparison" judging. How can a judge so effectually satisfy the wishes of a disappointed exhibitor as to the merits of any particular variety in relation to its influencing the award when this

method is adopted? By carrying out a system of point judging reference can be made to any bloom in the stand, years after if necessary.

It is plain that Mr. Lambert's experience of point judging is limited, or he would not say "it means trusting to his mind's eye to carry size, colour of say twenty-four or forty-eight blooms to a distance," because just the opposite is the case. Every bloom is individually appraised, the total value of the stand in number of points determining its position, leaving the mind free for the next stand, and dispenses with the necessity of carrying stand after stand of blooms about the exhibition (no small matter when forty-eight classes are under consideration), very much impeded too by the public when they are admitted before judging is completed.

Mr. Lambert's method of granting a point for freshness after two stands are found equal comes quite as a revelation to me. From what I have seen of judges while making their awards, this point in a bloom is determined at first, and not left to decide the issue. If Mr. Lambert means by colour in relation to the arrangement of the blooms, or even to one stand having a greater variety than the other, I agree with the adding of an extra point; but if he means the colour, good or bad, of any bloom, then I do not agree with him, as that ought to be determined at first, as it is one of the salient points in a good bloom. Mr. Lambert is not quite clear on this latter point, but as he links colour with freshness the inference is that he means the colour of individual blooms.

At how many exhibitions does Mr. Lambert judge in one season where the number of incurred blooms exceed one that is deserving of the maximum number of points, or even in the Japanese section? Adjudicators with a wide experience inform me seldom is the case that more are found. When awarding the class prizes the best bloom is generally "spotted" by the number of points it merits. I should have no hesitation in awarding such a bloom the premier honour. Why judges carry such a bloom around for comparison before finally deciding the position of premier is to save time in carrying others to that "spotted," in case one should be met with deserving of an equal number of points; but as this is I may say almost unprecedented the difficulty of determining is easily settled.

A judge of experience would have no trouble in settling the question of superiority between two blooms no more than he would have in finding the strongest claim of one bunch of Grapes over that of another, but when twelve or more have to be decided, and all not on an equal basis, the method of defining the accuracy of judgment must be altered to meet the case. —SADOC.

## ROYAL HORTICULTURAL SOCIETY.

MARCH 28TH.

THE Drill Hall has rarely presented a more brilliant appearance than it did on Tuesday last, the building being full of exhibits, comprising stove and greenhouse plants, Ferns, Roses, hardy flowers, and Orchids. Fortunately, too, the weather was sufficiently bright to admit of their being seen to advantage.

FRUIT COMMITTEE.—Present: Philip Crowley, Esq. (in the chair); with Dr. Hogg, Messrs. T. Francis Rivers, G. Bunyard, Harrison Weir, G. Taber, T. J. Saltmarsh, A. Moss, G. Woodward, W. Warren, A. Dean, A. H. Pearson, H. Balderson, F. Q. Lane, J. Hudson, G. Wythes, W. Bates, A. J. Laing, and J. Wright.

Mr. Bannister, The Gardens, Cote House, Westbury-on-Trym, sent a dish of the Standard Bearer Apple that was shown in the autumn and granted an award of merit. The fruit had kept fairly well. The variety is of the Blenheim type, symmetrical, and no doubt a good culinary Apple. Mr. John Crook, Ford Abbey Gardens, Chard, sent a dish of Sturmer Pippin Apples that had been kept in a shed, and subjected to several degrees of frost. The fruits were firm, but possessed no flavour, as is generally the case with Apples that have been subjected to frost.

Mr. G. Wythes, Syon House Gardens, sent a box of Vicomtesse Hericart de Thury Strawberries, fine fruit, excellently coloured, and well flavoured. A cultural commendation was unanimously awarded. Mr. Wythes also sent a dish of the St. John's Fig, nearly ripe (vote of thanks). A similar mark of recognition was accorded to Mr. T. Osman, Ottershaw Gardens, for a dish of Strawberries, also a plate of white fleshy Mushrooms. Mr. S. Hardy, Ash House, Parsons Green, sent a collection of Mushrooms packed for market—very fine produce, for which a cultural commendation was awarded.

Mr. T. Lockie, The Gardens, Oakley Court, Windsor, sent an excellent brace of Lockie's Perfection Cucumber. The fruits were about 16 inches long, faultless in shape, and good in colour. They were cut on the 25th inst., the plants having been raised from seed sown January 9th. A cultural commendation was unanimously awarded. Mr. Harrison Weir sent Filberts gathered in 1891. They were kept in tins buried in the garden, and were fresh and firm, though with signs of germination apparent in some of them. (Vote of thanks.)

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); Rev. H. H. D'Ombain, Messrs. Owen Thomas, H. Herbst, R. Dean, C. T. Druery, G. Stevens, R. B. Lowe, G. Bause, J. Ross, G. Gordon, W. Furze, C. Jeffries, C. E. Shea, H. Turner, C. Noble, J. D. Pawle, G. Paul, H. B. May, J. Fraser, J. Jennings, R. Owen, G. Nicholson, and James Walker.

Mons. Henry de Vilmorin exhibited a few flowers from the Riviera, chiefly Anemones and Narcissi. Messrs. Paul & Son, The Old Nurseries, Cheshunt, had a splendid group of Roses in pots Lilacs, Amaryllis,

Aucubas, and hardy flowers. It was one of the most attractive features of the meeting (silver Flora medal). Mr. H. B. May contributed a collection of Ferns, and noteworthy amongst which were *Pteris serrulata densa*, *Adiantum Mariesi*, *Hypolepis Bergiana*, *Adiantum versailleense*, *Pteris Reginae cristata*, *Pteris serrulata gloriosa*, and *Leucostegia immersa* (silver Banksian medal). W. M. Bullivant, Esq., Beckenham (gardener, Mr. Cresswell), had a collection of finely grown *Cinerarias*, the plants being of great size and full of bloom (silver Banksian medal). Mr. W. R. Newport exhibited a collection of Stocks called Model White, carrying good trusses for the time of year (vote of thanks). Messrs. J. James & Son sent a collection of their *Cinerarias*, the plants being dwarf, and the quality of bloom very marked (silver Banksian medal). The St. George's Nursery Co. had a very extensive display of *Cyclamens*, of which they make a specialty, and which they grow exceedingly well (silver Flora medal). Mr. Moore, The Botanic Gardens, Glasnevin, sent *Hoya cinnamomifolia*, *Brownea grandiceps*, and *B. ariza*, the enormous and richly coloured flowers of the two latter being effective though faded. Capt. Torrens contributed the beautiful *Schizocodon soldanelloides*.

Messrs. Hugh Low & Son invariably make their mark when they exhibit, and their group on the present occasion was of the customary high quality. It consisted of stove and greenhouse plants, chiefly hard-wooded, such as *Boronias*, *Azaleas*, *Diosmas*, *Chorozemas*, *Acacias*, *Ericas*, *Eriostemons*, *Genistas*, *Pimeleas*, and others. These plants are not so popular as they used to be, but they are unquestionably beautiful (silver Flora medal). Messrs. E. D. Shuttleworth & Co., Limited, sent a group of healthy and well-flowered greenhouse plants bearing their usual mark of quality. They also had a number of Daffodils (silver Banksian medal). Messrs. J. Peed & Son had a mixed group of foliage plants and Orchids, all well coloured, well flowered, and in admirable condition (silver Banksian medal). Messrs. J. Laing & Sons contributed stove and greenhouse plants intermingled with a few Orchids. The *Clivias* and *Caladiums* which they grow so well were a prominent feature of it, but all the plants were clean, healthy, and attractive (silver Flora medal). Messrs. Robert Veitch & Sons sent *Rhododendron gloxiniaeflora* and *Olearia stellulata* (see awards). Messrs. James Veitch & Sons sent *Magnolia stellata* (Halleana) pink and white varieties, *Chionanthus virginicus* (cultural commendation), *Rhododendron Yellow Gem*, and several *Amaryllis*. Messrs. B. S. Williams & Son sent several fine *Amaryllis*. Messrs. Barr & Sons were represented by an extensive and beautiful display of Daffodils and other hardy flowers, most of the popular varieties of the former being shown (silver Banksian medal). The first prize in the competition for Daffodils went to the Rev. S. Eugène Bourne, Dunston Vicarage, Lincoln; and the third to the Rev. G. P. Haydon, Doncaster. Messrs. W. Cutbush & Son had a group of *Azalea mollis* and *Epacris* which lent a distinct and pleasing feature (silver Banksian medal). The Rev. E. H. Engleheart exhibited a collection of hybrid and seedling Daffodils of his own raising, many of which were very beautiful, and engaged the close attention of the Daffodil Committee.

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); Messrs. J. O'Brien, De B. Crawshaw, H. M. Pollett, H. Ballantine, T. W. Bond, R. B. White, C. J. Lucas, W. H. White, E. Hill, J. T. Gabriel, T. B. Haywood, J. Jacques, Jas. Douglas, S. Courtauld, A. H. Smee, T. Statter, and Dr. Masters.

Orchids were shown somewhat extensively, and there was plenty to interest both general visitors and specialists. Several of the plants mentioned in the following notes are described more fully in "Certificates and Awards." Messrs. F. Sander & Co. had a diversified and delightful collection, noteworthy in which were *Cattleya Trianae alba*, *Odontoglossum Andersonianum guttatum*, several varieties of *Odontoglossum Pescatorei*, such as *picturatum* and *Model*, *O. Reichenheimi*, *Cattleya dolosa*, *Dendrobium nobile albiflorum*, *D. Dalhouseianum*, splendidly bloomed, *Cypripedium Rothschildianum*, *Oncidium fuscum*, *Spathoglottis Kimballiana*, and *Restrepia antennifera* (silver Flora medal). Sir Trevor Lawrence, Bart., sent an *Angraecum* species (cultural commendation), *Dendrobium micans* (*Wardianum* × *lituiflorum*), *D. Venus* (*nobile* × *Falconeri*), *D. superbum* *Burkei*, *D. anosmum* *Dayanum*, *D. cretaceum*, and *Odontoglossum Nötzlium* (*Cochlioda Nötzliana*). J. W. Temple, Esq. (gardener, Mr. Bristow), sent *Lycaste plana* and *L. plana* *Templae*. W. C. Walker, Esq., contributed *Odontoglossum Andersonianum* and *Cypripedium Boxalli*. G. R. le Doux, Esq., had *Cattleya intermedia Faustiana*, *Odontoglossum triumphans splendens*, *O. Andersonianum* variety, and *Cypripedium barbatum majus*. Messrs. Pitcher & Manda were represented by a small collection of *Cypripediums* and *Cattleya speciosissima*, *Manda's* variety. C. L. M. Ingram, Esq. (gardener, Mr. T. H. Bond), sent *Cypripedium T. W. Bond* and *C. compactum* × *C. candidulum* × *calurum*. W. R. Lee, Esq., sent *Dendrobium Wardianum album*, and Thos. Statter, Esq., contributed *Dendrobium nobile Storeri*, *Cypripedium Exul* var. *annamense*, and *Dendrobium heterocarpum*. N. C. Cookson, Esq., had *Dendrobium nobile*, *Oakwood* variety, *Dendrobium Sibyl* (*bigibbum* × *Linawianum*), and *D. Bryan*. H. J. Elwes, Esq., Andoversford, sent a basket of hardy Orchids, amongst which was *Ophrys sphegodes*, *Orchis tridactyla*, and *Calypso borealis*, the latter receiving a botanical certificate. Messrs. Heath & Sons sent *Odontoglossum excellens* × *triumphans* (cultural commendation). Messrs. J. Veitch & Sons sent *Dendrobium Alcippe* (*D. Wardianum* × *D. lituiflorum* *Freemani*). Baron Schröder sent several attractive *Odontoglossums*, and Messrs. W. L. Lewis & Co. contributed a small but beautiful mixed group. P. Crowley, Esq., sent a group comprising *Ada aurantiaca*, *Cypripedium villosum*, and a few other Orchids (silver Banksian medal).

## CERTIFICATES AND AWARDS.

*Cattleya speciosissima Manda's* variety (Pitcher & Manda).—A magnificent variety, the lip being flattened, circular, and about 3 inches across. The colour is rich magenta on a white ground. The petals were of enormous size, and with the sepals of a soft blush shade (award of merit).

*Odontoglossum Nötzlium* (Sir Trevor Lawrence, Bart.).—Note-worthy for its brilliant colouring, the sepals, petals, and lip being brilliant red, the column tipped with magenta. The flower is about 1½ inch across, and the plant of dwarf habit (award of merit).

*Cypripedium T. W. Bond* (C. L. M. Ingram, Esq.).—A cross between *Swonianum* and *hirsutissimum*. The lip is long and narrow, the petals curved, obtuse, and having the colouring of *C. hirsutissimum*. The dorsal sepal is broad, but pointed, being marked with lines of dots and a greenish ground (award of merit).

*Dendrobium Wardianum album* (W. R. Lee, Esq.).—A remarkable and beautiful variety, the sepals and petals pure white, the apical area of the lip also white, the throat yellow (first-class certificate).

*Dendrobium Sibyl* (N. C. Cookson, Esq.).—A cross between *D. bigibbum* and *D. Linawianum*, with drooping rosy mauve flowers, the throat white with a central blotch of yellow and crimson spots (award of merit).

*Dendrobium Bryan* (N. C. Cookson, Esq.).—A cross between *D. luteolum* and *D. Wardianum*, but the parentage of the latter is not very marked. The flower is of a uniform pale lemon hue, but the throat is lined with reddish brown. It is a decidedly attractive acquisition (first-class certificate).

*Cypripedium* × *microchilum* (J. Veitch & Sons).—A cross between *C. Druryi* and *C. niveum*, the former being the pollen parent. It partakes very much of the character of *C. niveum*, but the lip is much smaller. The flower is ivory white, the dorsal sepal and petals having a central bar of magenta, and lightly dotted with the same colour (award of merit).

*Amaryllis Siren* (J. Veitch & Sons).—A beautiful light orange red flower with rounded segments. One of the most perfect blooms yet seen (award of merit).

*Rhododendron Yellow Gem* (J. Veitch & Sons).—A beautiful variety, resulting from a cross between the Sumatra and Java sections. It has clear light yellow flowers 2½ to 3 inches across (award of merit).

*Magnolia stellata* (Halleana), pink variety (J. Veitch & Sons).—A soft pink variety of *M. stellata*, the outer portion of the petals much deeper in colour than the interior (award of merit).

*Olearia stellulata* (R. Veitch & Sons).—A dwarf sort, producing thick clusters of pure white starry flowers, attractive, and likely to prove useful (award of merit).

*Clivia Beechdale* (J. C. Geiselbrecht, Esq.).—A variety of exceptionally rich colour, and the truss fine. The hue may be described as a brilliant deep orange vermillion (award of merit).

*Rhopaloblaste hixande* (J. Laing & Son).—A little known but elegant Palm, which would prove useful for decorative purposes (award of merit).

*Schizopodon soldanelloides* (Capt. Torrens).—This is a beautiful little plant brought by the exhibitor from Miyanoshta, Japan, in 1891; named at Kew, and stated by the authorities there to have been the first living plant brought to England. It is a dwarf plant, growing but 2 or 3 inches high, and with soft rosy flowers with deeply lacinated or fringed segments (first class certificate).

*Cyclamen Princess May* (The St. George's Nursery Co.).—Soft rose flowers of large size, the plant dwarf and a free bloomer (award of merit for the strain).

*Brownea ariza* (Glasnevin Botanic Gardens).—A magnificent species with enormous flowers of a rich lustrous scarlet, and with glossy, fragile, lanceolate foliage (first class certificate).

*Scilla sibirica vera alba* (De Graaff Brothers).—A pure white variety, and a charming companion to the blue (award of merit).

*Amaryllis Lightning* (Paul & Son, Cheshunt).—A brilliant crimson variety, very rich in colour (award of merit).

*Lilac Alphonse Lavallée* (Paul & Son, Cheshunt).—A beautiful semi-double variety, with very large trusses of bloom, colour lilac (award of merit).

*Cereus Hoveyi* (F. Ross).—A most brilliant sort, with large flowers, colour deep red suffused with bluish magenta (award of merit).

*Aucuba japonica fructu-alba* (Paul & Son, Cheshunt).—A white-fruited variety of the type with green foliage, the berries large (first-class certificate).

*Amaryllis Ophelia* (B. S. Williams & Son).—A very distinct variety with pointed segments, ground colour white, flaked and dotted with carmine and edged with the same colour (award of merit).

## THE FLOWERS OF THE RIVIERA.

THE paper on the above subject by Mons. Henry de Vilmorin of Paris, was ably read at the afternoon meeting by the Rev. W. Wilks. Dr. Hogg occupied the chair. Owing to a serious illness Mons. de Vilmorin was prevented attending, but his son, Mons. Phillip de Vilmorin, was present to give any information respecting the text of his father's paper.

The essayist first noticed briefly the climatic conditions which prevail on the Riviera, and pointed out how favoured it was in being sheltered from the north winds by hills and mountains, and in having more sunny days by three to one than we have here in England. Sharp and protracted frosts were unknown, except in the very low lying

districts. Though the temperature was so favourable, protection for various plants was not by any means despised. This consisted principally of glass frames built with a centre bar and sloping almost to the ground, and having the ends stuffed with straw or fern. Greenhouses were by no means common, though many of the flower growers had built them, and which were mainly used for affording a constant supply of bush Roses, French Beans, Tomatoes, and Strawberries during the months of January and February. In these houses hot-water pipes were fixed in case of emergency, though, said the essayist, their use had very seldom to be resorted to, the growers depending on the natural influences of light and air to develop the plants and trees.

Foremost amongst the many trees grown in the Riviera for market purposes were the Australian Mimosas, and of these *Acacia dealbata* stood pre-eminent. The tree rapidly grows to a large size, and is during the months of January and February a beautiful sight. The soil most suitable to this tree is found only on the hills round Cannes, as it does not thrive on clayey soils. *Eucalyptus globulus* was also very largely grown for the markets, the sprays when covered with their white blooms being very effective. Roses, the essayist said, were a great feature and source of income to the inhabitants of the Riviera. The varieties grown for spring blooming were *indica* major and *Banksian* amongst others. Ten years ago the Dean of Rochester said that ninety-nine out of every hundred Roses grown in the Riviera were the *Safrano* variety, and the same per-centage holds good to-day. It blooms profusely all the year round, and is much appreciated by purchasers. Climbing Roses were also very largely grown on walls, and were very remunerative. White and yellow *Marguerites* were extensively cultivated, as were *Pinks*, *Roman Hyacinths*, *Narcissi*, *Jonquils*, hybrid *Gladioli*, *Allium neapolitanum*, *Tulips*, and *Freesias*.

*Anemones* were, said the essayist, indigenous to the Riviera, and as they carried well and revived in water, were grown by the acre. Two single varieties were still to be found wild—purple and scarlet, the latter being by far the most beautiful and in the greatest demand, and is consequently to be found in much less numbers. *Violets* were extensively grown, and *Mignonette* was in very great demand. The essayist, in conclusion, said that anyone who would go to the Riviera to spend their Easter holiday would be amply rewarded by the delightful flowers and the blue sky and sea which would welcome him on his arrival.

A hearty vote of thanks was accorded to Mons. de Vilmorin for sending his admirable paper, to Rev. W. Wilks for reading it, and to Dr. Hogg for presiding at the meeting.

### IS SOOT A GOOD MANURE?

IN reply to "W. C." (page 199) I may say that soot is a very excellent fertiliser as well as purifier of the soil. During the last twenty-two years I have annually used large quantities of soot in various ways in the gardens here with most satisfactory results. All ground to be cropped with Onions, Parsnips, Carrots, and Turnips is surface-dressed with soot immediately before drawing the drills for the reception of the seed; also before making plantations of Lettuce, Parsley, and Carnations, plants liable to the attacks of the grub and Onion maggot, sufficient soot is strewn over the ground to discolour it.

Before transplanting Cabbages, Cauliflowers, Savoys, Broccolis, and Borecoles, the roots of the plants are dipped into a "puddle," into which a double handful of soot has been stirred. This renders the roots distasteful to the attacks of the grub and other creatures injurious to root growth. Thus it is that our crops of Onions, Parsley, and similar things are never attacked by the maggots or wireworm, the ground consequent upon the frequent applications of soot being quite free from those troublesome pests. So much for the efficacy of soot as a purifier of the soil and preventive to the attacks of insects on the roots of plants, not only growing in the open ground but also in pots and tubs.

Anyone desirous of demonstrating the efficiency of soot as a manure can easily do so by leaving space for a few rows of Onions undressed with soot and noting the result. The growth resulting from seed sown in the ground over which soot had been scattered will be of a rich dark green colour, while that obtained from the undressed ground will be less vigorous and of a comparatively pale green colour, the colour of one lot of plants being markedly distinct from the other. Again, top-dress a portion of an impoverished lawn with a sifted mixture consisting, say, of three parts good soil and one of leaf mould, and to this mixture add soot at the rate of a gallon of the latter to a bushel of the former before applying it to the remaining portion, and the resulting growth will afford conclusive evidence in favour of soot being a valuable fertilising agent. A good surface dressing of soot pointed into a Vine or Peach border with a five-tined fork before applying clear tepid water will greatly assist in the production of crops of a high order.

A peck or two of soot tied in a piece of coarse cloth and then dipped into a tub of tepid water, and squeezed well into it for a few minutes before applying it at the roots of Pine Apple plants, fruit trees, Roses, Camellias, and Orange trees growing in pots and tubs, will prove very beneficial and productive of good results. A solution of lime and soot applied to Peach walls with a stiffish whitewash brush before nailing the trees thereon early in spring will tend to destroy the larvæ of insects which would otherwise prey on some of the ripe fruit in the autumn. Solutions of the same mixture applied through the garden engine in winter to fruit trees which are covered with moss and lichen will not only destroy those parasites but will also kill the larvæ of insects located

therein. A sprinkling of soot put over the drainage in pots being prepared for the reception of Vines and other plants which have to be plunged in leaves will prevent the ingress of worms, and at the same time conduce to the well-being of the plants.

A mixture of soot and lime placed round young Melon and Cucumber plants about 2 or 3 inches from the stems will ward off the attacks of slugs. A line of the same mixture strewn along between the Box edging and plantations of young Lettuce plants will serve a like purpose. It may be used in a similar manner on each side rows of Peas and Cauliflowers, encircling the plants of the latter. The soot should be kept in the dry until used. Here, having all the soot from the Castle and other buildings on the place for use in the garden, I have a house for its storage.—H. W. WARD, *Longford Castle*.

ACCORDING to "Griffiths," soot is a good manure when applied as a top-dressing, not only to agricultural produce and grass land, but is also valuable for vegetable crops. Nicholson says:—"The fertilising effect of a top-dressing of soot is very decided, and seems to be due in a great degree to the presence of sulphate and chloride of ammonium." Apart from its use as a manure, it is decidedly valuable as a remedy against larvæ that lie underground during the day and crawl up to feed upon the plants at night. Soot is considered to be an excellent stimulant for *Chrysanthemums*, restoring the lost colour to the leaves when these have become pale, applied either as a top-dressing or in liquid form to the roots, or even used for syringing on the foliage. *Chrysanthemum* cultivators in the neighbourhood of Liverpool use soot in large quantities as a top-dressing to their plants. Market gardeners in some instances depend solely on soot as a manure for their Gooseberry trees, and with good results.—E. M.

### EXPERIENCES WITH BROCCOLI.

INQUIRIES have been made for experience with Broccoli in hard and in loose land, also whether midseason or late varieties stand severe weather best. I believe in good firm soil for all the Brassica family, and never think of digging the ground for them. I would prefer planting with a crowbar, and there are few seasons when it is not used for the purpose. At the same time, I do not consider it absolutely necessary, so far as my experience goes.

On August 6th last year I planted about 300 Late Queen and Methven's June, after Potatoes on land that was burned two years ago, and which is now very porous. The plants were heeled over to the north the second week in November, and another 100 Late Queen lifted out of an orchard and laid in beside them. Out of the whole number I do not think twenty have been killed, while close beside them Cooling's Matchless in the open succumbed to the frost. Some of Model are quite fresh. The seed was sown on May 4th. I find it little use to grow many midseason Broccoli, and have not found one equal in hardiness to the late varieties.

In 1891 I planted about 500 Broccoli after the Strawberries were cleared off, and the ground was so hard that we had to make drills with the pickaxe (as being the easiest tool to work), and fill them with liquid manure to soften the soil. The plants grew dwarf, and I thought they would not need laying down, so having to clear a pit out I put spent hotbed manure on as a winter mulch, covering the stems well, but in the end I only saved about half of them. The varieties were Model, Late Queen, and Methven's June. The first two came in about the same time, while the other followed. The above varieties are the best I have tried.

I have visited two gardens lately and noted the Broccoli, more especially the effect of early sowing and planting too close. Some sorts were all gone, others varied to half, while another sharp frost would have destroyed the remainder. I have come to the conclusion that it is best and safest neither to sow nor plant too early; lay all to the north before severe weather sets in. If done too soon the leaves turn up again, and a heavy fall of snow then breaks them down, while if laid almost flat the leaves are turned over and protect the crowns. Some may think by this treatment the heads will be small, but that is not always so, and it is better to have small heads than none.—YOUNG HAND, *Somerset*.

### CRYSTAL PALACE SPRING SHOW.

MARCH 25TH.

THE Exhibition of spring-flowering plants, held at the Crystal Palace on the above date, was of a bright and diversified character. Taken as a whole the exhibits were of good quality, and in some classes the competition was somewhat keen. Hyacinths were specially fine, as they appear to be generally at most spring shows this year, and the same remark applies to Tulips. Cyclamens also made a good display, as likewise did the miscellaneous exhibits.

Hyacinths and Tulips in the open classes were exhibited in grand form. For thirty-six Hyacinths Mr. J. Douglas, gardener to Mrs. Whitbourne, Great Gearies, Ilford, was first, showing a splendid collection of well-developed spikes. The best of these were Lord Derby, Koh-i-Noor, Electra, King of the Blues, Sultan, Mont Blanc, La Grandesse, Vuurbaak, and Bird of Paradise. Messrs. H. Williams & Sons, Fortis Green, East Finchley, were second, the spikes being fresh, but not quite so large as in the first prize collection. Ida, Fabiola, Czar Peter, and Lord Derby were specially good. Messrs. B. S. Williams & Son, Upper Holloway,

secured a third position. There were five exhibitors in this class. In the amateurs' class for twelve Hyacinths Mr. H. Shoesmith, gardener to M. Hodgson, Esq., Shirley, was first, showing amongst others good Queen of the Blues, King of the Blues, Lord Derby, Czar Peter, and Gigantica. Mr. F. Barr, West Norwood, was second. Mr. Douglas was again first in the class for thirty-six Tulips, three in a pot. These were remarkably well grown, and carried fine flowers. The best varieties were Vermilion Brilliant, Proserpine, Keizers' Kroon, Joost Van Vondel, and Van der Ncer. The second prize went to Messrs. B. S. Williams for a collection of well-developed blooms, Messrs. H. Williams & Sons being third. There were four entries in this class. Mr. H. Shoesmith was the only exhibitor of twelve Tulips in the amateurs' section, but was awarded first prize.

Narcissi were not very extensively shown. Mr. J. Douglas was awarded first prize for twenty-four Polyanthus Narcissi, three in a pot, staging an even collection. Conspicuous amongst these were Her Majesty, Jaune Supreme, Bathurst, Gloriosa, and Grand Monarque. There was no other exhibitor in this class. For twenty-four Daffodils, Messrs. H. Williams & Sons were awarded first prize. Princeps, Van Zion (double and single), were among the best of these. Mr. J. Gibson, gardener to Mrs. Berkeley James, The Oaks, Carshalton, was first for twelve Narcissi (Daffodil section). Mr. H. Shoesmith was second.

Cyclamens were best shown by Mr. Thomas Prestridge in the open classes, this exhibitor being awarded first prize for thirty-six plants. The specimens staged were well flowered. The second prize went to the St. George's Nursery Company, Hanwell. Certificates of merit were adjudged Cyclamens The Duchess (pure white), and Princess of Wales (rosy pink) in this exhibit. Mr. F. May, St. Margaret's, Twickenham, was third. Mr. W. Slogrove, Gatton, Reigate, was first in the amateurs' section for twelve Cyclamens; Mr. J. Hughes, gardener to G. R. Higgins, Esq., Eastlands, Dulwich, S.E., second; and Mr. C. Lanes, gardener to E. H. Coles, Esq., Burnwood, Caterham, third. Mr. A. H. Morle, Fenchurch Street, E.C., had the best eighteen pots of Mignonette as grown for market; the second prize going to Mr. A. White, Stanmore Park Gardens, Stanmore; Mr. A. Carter, Penge, was third. Mr. J. Jannock, Dersingham, Norfolk, was first with Lily of the Valley, staging plants with well developed spikes. Messrs. H. Williams & Sons were second, and Mr. Morle third. For twelve Amaryllis Messrs. G. Paul & Son and J. Douglas were the only exhibitors. Messrs. Paul and Son secured the first prize, showing some very fine seedlings, and George Elliott, Titian, Princess, and W. Coomber. Certificates of merit were awarded the two last named. Mr. Douglas's flowers were smaller but fresh. Mr. Douglas was, however, awarded first prize for six Amaryllis.

Cinerarias were good, although not extensively staged. Mr. J. Ford, gardener to Sir C. Pigott, Bart., Wexham Park, Slough, was first with twelve plants, staging well flowered specimens. Mr. Douglas was a close second, and Mr. J. Slater, gardener to J. Nothard, Esq., York House, Lower Sydenham, was third. Mr. R. Wells, Longton Nursery, Sydenham, was awarded first prize for twenty-four greenhouse Azaleas. The plants were rather small, but profusely flowered. Primulas were not shown in first-rate condition, those staged by Mr. J. Ford being the best.

For a group of flowering and foliage stove and greenhouse plants Messrs. J. Laing & Sons, Forest Hill, S.E., were adjudged premier honours for a charming arrangement. This group comprised, among other things, Palms, Clivias, Caladiums, Ericas, Azaleas, Ferns, and Orchids. Conspicuous amongst the latter was a plant of *Cypripedium Elliotianum*, to which a certificate of merit was awarded. Messrs. J. Peed & Sons, Roupell Park, S.E., were placed second for a well arranged group, Messrs. B. S. Williams & Son, Upper Holloway, being third.

Miscellaneous exhibits also made a good display. Messrs. W. Cutbush & Sons, Highgate, sent a large group of greenhouse flowering plants, which formed quite a feature in the Exhibition. Messrs. G. Paul & Son sent a number of Roses in pots, and Messrs. Ryder & Sons, Sale, some *Primula Sieboldi* and new floral menu cards. Messrs. W. Paul & Son, Waltham Cross, sent a dozen boxes of *Camellia* blooms and some Roses in pots. Certificates of merit were awarded to *Roses Christine de Noüe* (deep pink), and *Lady Henry Grosvenor* (white, blush centre). Mr. J. Jannock, Dersingham, sent some pans of *Lily of the Valley*, the flower spikes being very fine. Bouquets of *Anthuriums* and *Clivias* were staged by Messrs. J. Peed & Sons, who also had *Anthurium Roupelli*, *A. Weaveri*, *A. Knighti*, and *Pteris Peedii*, to which certificates of merit were awarded. Mr. Hardy, Parsons Green, sent a number of baskets of Mushrooms cut from the open air, and the St. George's Nursery Co. staged a collection of *Cyclamen*.

#### GARDENERS' CHARITABLE AND PROVIDENT INSTITUTIONS.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—*Secretary*, Mr. G. J. Ingram, 50, Parliament Street, London, W.C.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—*Secretary*, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

ROYAL GARDENERS' ORPHAN FUND.—*Secretary*, Mr. A. F. Barron, Royal Horticultural Society's Gardens, Chiswick, London, W.

#### UTRICULARIA RHYTROPHYLLA.

WHEN well grown some of the most notable of the Bladderworts are exceedingly pretty, and should be more frequently seen in cultivation. One of the best of these is that depicted in the illustration

FIG. 52.—UTRICULARIA RHYTROPHYLLA.

(fig. 52), viz., *Utricularia rhytrophylla*. The specific name is apparently derived from a Greek word referring to the long, narrow, strap-like leaves, but the chief character of the plant rests in the flowers. These are large, of a fine purplish hue, with an orange-coloured projection at the base of the broad rounded lip-like portion, and are borne in slender graceful racemes from the base of the plant. It thrives well in small baskets of peat and sphagnum suspended from the roof of an intermediate house.

#### FRUIT FORCING.

**Pines**—Suckers or plants which were started at the beginning of March will have pushed roots and must not be subjected to more bottom heat than 90° at the base of the pots, raising these and placing some loose tan about them so as to allow the heat to escape, taking care to avoid checks. Preparations should be made for shifting the plants into the fruiting pots when they have filled the present ones with roots.

Use 9 or 10-inch pots for Queens, 10 or 11-inch for Smooth-leaved Cayenne, and 11 or 12-inch for Providence, watering the plants a day or two previously so as to have the soil moderately moist when they are potted. This will not be required for another ten days or a fortnight, but the soil, good fibrous loam, should be had under cover, the pots and a fermenting bed be prepared. The bed in which the plants have been started may answer by replenishing it if needed by the addition of fresh tan, mixing it with the old to a depth that will afford the temperature required—namely, 95° at the base of the pots until the roots reach the sides, when 90° is more suitable. Keep the air about such plants well charged with moisture during the time the house is closed, employing no more fire heat than is absolutely necessary to maintain a temperature of 70° to 75° on mild nights. Ventilate slightly at 80°, liberally at 90°, closing with sun heat at 85°, at which time syringe the plants. Fruiting plants, which should not be syringed when they are in bloom, require similar treatment. Water the plants as needed, examining them twice a week for that purpose.

**Cherry House.**—Trees that have set a heavy crop should have the fruits thinned with scissors, removing the smallest and ill-shapen, and as they will be less vigorous than those with fewer fruit, the demand for nutriment will be greater, and whilst they will be benefited by the application of liquid manure, those lightly cropped should have water only. Ventilate freely at 50°, and fully at 60° to 65°, and employ fire heat only to maintain the day temperature at 50° to 55°, with a little air, and 50° or 5° less on cold nights. Syringe the trees twice a day after the fruit is set and swelling, keeping the border moist by damping it whenever the surface becomes dry. When the shoots have made four or five joints, pinch out their points to form spurs; growths required for furnishing the trees should be tied in position early, and be carefully trained in their full length. Keep a sharp look out for grubs on the leaves, and aphides must be kept under by repeated fumigation with tobacco paper, as if they get much hold they are not only difficult to exterminate, but spoil the appearance of the fruit. Over-fumigation seriously cripples the foliage, and must be avoided by moderate doses on two or three consecutive evenings, having the foliage dry. Trees in pots must be well supplied with water and have top-dressings of loam and manure, with a sprinkling of "artificial" occasionally, and liquid manure twice a week.

**Melons.**—Attend to thinning, tying, and stopping the shoots twice a week. Plants growing in beds over hot-water pipes require more water than those having the bottom heat supplied by fermenting materials. Plants swelling their fruit will need copious supplies, and if the roots are in shallow or narrow borders with ample drainage tepid liquid manure in a weak state should be given whenever the application of water is necessary, and it will compensate for the limited root action; but that may be accelerated by top-dressing of loam, and a sprinkling of superphosphate occasionally. Commence ventilating at 70° on fine mornings, always at 75°, and increase it with the rising temperature, keeping it at 80° to 90° in the daytime from sun heat, closing between 85° and 90°, and so as to run up to 95° or more, with plenty of atmospheric moisture, a high temperature and plenty of moisture being necessary when Melons are swelling. Maintain a night temperature of 65° to 70°, and 70° to 75° by day artificially. Place the necessary supports to the fruits.

Succession plants will need frequent attention in training and regulating the growths. They should be trained with a clear stem to the trellis, rubbing off all the side shoots as soon as discernible, and not stopping the leader until it has grown one-third across the trellis if trained on the extension system, or two-thirds on the cordon method. In the former case the main shoots are trained 12 to 15 inches apart and the laterals spread over the space between without crowding; but on the cordon plan every alternate lateral on opposite sides of the leading shoot should be removed to prevent crowding. The laterals will show fruit at the second or third joint. A somewhat dry atmosphere should be maintained when the plants are in flower, and until they have set the fruit, impregnating the flowers every day as they become fully expanded, stopping the laterals at one joint beyond, until a sufficient number for the crop are obtained on each plant of the same stage of growth.

**Melons in Pits and Frames.**—Where the plants are trained over the surface of the beds young plants will need stopping at the second or third leaf, and the shoots resulting being reduced to four train two to the front and two to the back of the frame, stopping them when 15 inches from the sides. It will be necessary to thin or rub off the laterals to some extent so as to prevent overcrowding, keeping the collars free from growths, and fertilise the flowers about midday on fine days when they are fully expanded, stopping at the same time one joint beyond the fruit. Sow and plant in accordance with the extent of the establishment. Attend to the linings at weekly or such intervals as circumstances occasion, and protection over the lights will be necessary at night as a means of retaining the heat by preventing radiation from the glass.

**Cucumbers.**—Shading for an hour or two at midday when the sun is brightest will prevent the foliage flagging, and is absolutely necessary after a period of dull weather to prevent the plants receiving a severe check, if not actual injury to the foliage. Assist plants in full bearing with applications of weak tepid liquid manure, and supply a little fresh loam to the roots. If horse droppings are used they must be previously sweetened, and not applied too abundantly, nor too often, or it will injure the foliage. Stopping and training must be attended to at least once a week. Plants that have been in bearing for any length of time should have the old exhausted growths removed with a small fork, not

injuring the roots, and replacing it with fresh soil—lumpy and rich, previously warmed—the plants will continue to supply good fruit some time longer, the exhausted growths being cut out, and fresh bearing shoots encouraged.

If worms are troublesome expel them with soot water, half a peck to thirty gallons of water, or sprinkle a little superphosphate on the surface occasionally. Canker at the collar and in the stems may be subdued by rubbing quicklime into the affected parts. Damp the floors about 7 A.M., and again at 3 P.M., syringing the plants gently on warm afternoons. Maintain a night temperature of 70°, 5° less in the morning, 70° to 75° by day artificially, keeping through the day at 80° to 90° from sun heat, and close sufficiently early to run up to 90°, or even 100°, with abundance of atmospheric moisture. Ventilate early and moderately, avoiding sudden changes of temperature, and above all cold currents of air, which cripple the foliage, stunt the fruit, and cause it to swell irregularly or die off at the end.

**Cucumbers in Pits and Frames.**—A good degree of heat should be kept by the renewal or application of manure linings, taking care to avoid rank steam. Supply water carefully and moderately and early, for the nights are yet cold, employing thick night coverings. Train the shoots rather thinly, pegging them down as required, stopping one joint beyond the show of fruit. Add fresh warm soil to the hillocks or ridges as the roots extend. Ventilate early so as to get a change of air and the foliage fairly dry before the sun acts powerfully upon it, not lowering the temperature, but keeping through the day at 80° to 85° from sun, and close early in the afternoon, no harm accruing if the heat rise to 90° or 95°. Rank steam, however, must be guarded against, having a little ventilation constantly in case danger be apprehended from it.

**Strawberries in Pots.**—April is the principal month for forced Strawberries, the season then being at its height, and the labour entailed in supplying water and nourishment at the highest pitch. East winds are very prevalent and cutting in spring time; these and sharp winds from any quarter blowing directly on the berries in the early stages of swelling cause them to become dried and brown, so that they do not swell well afterwards. Neglect of watering will also have a similar effect on the fruit. Great attention must be given to this, examining the plants at least three times a day in bright weather, and whenever a plant needs water supply it thoroughly, alternating with liquid manure. Plants to furnish fine fruit should have the flowers thinned to a dozen or so on each plant, or when very fine examples are required the plants showing the largest flowers should have them reduced to six or eight. The plants should be brought forward in gentle heat in the first stages of swelling, affording plenty of atmospheric moisture while it remains green, but when it becomes whitish green increase the night temperature to 65°, 70° to 75° by day artificially, and 80°, 85°, or 90° on sunny days, continuing this until the fruit becomes red all over, when the temperature should be lowered to a minimum of 60° and a free circulation of warm rather dry air maintained, with water only at the roots to keep the foliage fresh, will be necessary to secure flavour.

#### THE KITCHEN GARDEN.

**Forced Asparagus.**—Supposing that forced Asparagus must be forthcoming till the open air produce is available, it will be necessary in many cases to lift more roots and put these in gentle heat. Place them direct into rich moist soil in preference to any that is poor or dry. In order to thoroughly exhaust the earlier started roots, prior to throwing them away as being of no further service, force gently and keep the soil about them constantly moist. Good early produce can be had by forcing Asparagus where it is permanently planted in narrow raised beds. If a deep trench is at once dug on each side of the bed and filled with moderately hot manure and leaves, the bed being further enclosed with boards, and either mats or glazed lights, there will be a gain of about fortnight, or enough to repay for the trouble taken.

**Asparagus Beds.**—Where the old fashioned plan of giving an autumn dressing of manure, the sides being chopped down, and the soil distributed over the manure, is still adhered to, the beds should be put into good order for the season. The shoots would come through the dressing and be all the better for the additional length of stem, but would be late, while the side roots, already mutilated in the autumn, would further suffer from exposure to sunshine and drying winds. Therefore lightly fork over the beds, working or raking some of the dressing right and left so as to well cover the sides. Asparagus roots ought not to be confined to narrow bounds, and if the alleys between raised beds are full of roots on no account injure the latter by digging and cropping with Cauliflowers. It is a common, but not economical practice.

**Manuring Asparagus Beds.**—Asparagus very often gets more manure than it really needs; in fact, heavy soils are not unfrequently rendered quite unsuited to the crop, owing to the free use of manures. If nothing but solid manure has been applied of late years, dispense with this for once, and give a dressing of newly slaked lime, applying this at the rate of 2 bushels to the square rod, lightly forking it into the surface. In many instances the roots and crowns are too near to the surface, where they are easily injured by spring frosts and summer drought. These ought to be dressed with short partially decayed manure; this, in its turn, being surfaced with fine soil. Supposing the crowns are covered with not less than 3 inches of fine soil, loosen this with a fork, and top-dress with short manure, this answering the three-fold purpose of a protection from spring frosts, fertiliser, and summer mulch. Salt is the manurial dressing most often applied, but it is quite unsuited to soils of a clayey nature, as it causes them to run

together badly, cracking following in due course. A too free use of salt is also responsible for many gaps in beds. Where the soil is light in character just loosen the surface, and then whiten it with coarse salt. Salt and Peruvian guano in equal quantities, applied at the rate of 8 lbs. to the square rod, suits medium soils admirably, so also does a light surfacing of nitrate of soda occasionally. Fish manure has been found very suitable for the beds generally, and this, soot, and guano are among the best dressings that can be applied to heavy soils.

**Seakale.**—This will soon be available from the open ground, the crowns in this case being heavily moulded over, or covered with pots, ashes, leaves, or other substitutes. In the former case the covering is frequently too slight, the Seakale growths pushing through, and the tops spoilt by exposure to the light before being observed. Therefore cover the rows with a ridge of soil of some kind, 15 inches high and as much through at the base. Any not partially covered ere this will have so much purple in the points as to be past blanching, but if allowed to grow naturally, and cut over before the flower heads are far advanced, a very succulent, mildly flavoured vegetable will be had. During the first fortnight in April is a good time to either sow seed or form a fresh plantation with root cuttings, the latter plan being the simplest and best. Therefore save all the thongs or strong side shoots attached to the old roots lifted for forcing, and if need be trace out and remove some from those still in the ground. All thongs should be near the size of a man's little finger, and about 4 inches long. Take a slanting snip off the thinnest end or that part to be buried the deepest, and bed them in rather thickly in boxes of light soil or sand. If placed in gentle heat for a few days the tops will callus and form buds, and root-action also commence, when if they are early planted out there will be fewer failures than when the cuttings are dibbled out direct where they are to grow. If it is desirable to largely increase a small stock of Lily White it will be found that quite stout roots will develop into plants if given the benefit of gentle heat, and these may be further split up.

**Seeds to be Sown.**—If the earliest sown Peas from any cause come up badly sow more seed at once in 3-inch pots, place in heat, and keep constantly moist, and serviceable plants will soon be ready for filling up the blanks. According as the earliest and second early Peas come through the ground make other sowings of successional varieties, it now being time such excellent varieties as Telephone, Duke of Albany, Criterion, Huntingdon, and such like were sown. With these might also be sown one or more of the later or main crop varieties, a good natural succession resulting. Sow Spinach at the same time. More Broad Beans, including the Windsor type, ought to be sown; but it is yet too early to sow Kidney Beans in the open, though a few dozen or scores of plants might well be made ready to succeed early Potatoes, according as these are cleared out of pits. Onions should be sown directly the ground is in a free working state, and so also ought Parsnips. Seed of Early Horn Carrots should be sown on a warm border, and with these Radishes may also be grown, the drills for Carrots being drawn 9 inches apart, and between these for the Radishes. Sow Leeks at once. If no Brussels Sprouts, Autumn Giant Cauliflower, and Veitch's Autumn Protecting Broccoli have been raised under glass, sow seed at once on a warm border, and net over if small birds are troublesome. Sow early and main crop Lettuces in drills 9 inches apart, and the ground being fairly rich some of the plants resulting may be allowed to heart in where they are raised.

#### PLANT HOUSES.

**Pelargoniums.**—Give the earliest plants that are showing flower a little artificial manure on the surface of the soil at intervals of two or three weeks until they have practically done flowering. Be careful not to allow the plants to become dry, and watch closely for aphides, and destroy them by fumigating with tobacco smoke directly they make their appearance. Large plants that are growing freely should have their shoots tied out, so that they will not crowd one another. Any of these plants that need more root room should be potted at once. Those required for the latest flowering, or any plants that are weak, may have the points of their shoots removed to induce them to break again into strong vigorous growth, which they will do if given abundance of air.

**Zonal Varieties.**—There should now be a plentiful supply of these plants in bloom, and in light airy positions they will continue to flower for a long time, providing stimulants in a weak state are given occasionally, or artificial manure is applied to the surface at intervals of three weeks. Plants in 3-inch pots, and that are needed for succession, should be placed into 5-inch pots. Give plenty of air to encourage a firm, sturdy growth. For autumn and winter flowering the necessary batches of cuttings should now be inserted. Place the cuttings singly in thumb pots, and in a short time they will root if placed in a structure where the temperature ranges about 60°. Cut back plants that have done flowering or from which cuttings have been taken, keep them on the dry side until they break into growth. Those cut back some time ago may have the old soil shaken from their roots, and the plants repotted in the same size pots. Keep these close until they are rooting freely, when more air should be given them.

**Fuchsias.**—Do not stop again the shoots of the earliest plants, but allow them to grow and come into flower. The later plants that were cut back are growing freely. The shoots may be again stopped, and the plants placed into larger pots if they need it. Plants that are just rooted may be placed into 3-inch pots. Another batch of cuttings should be inserted if sufficient stock has not been raised.

**Lilium Harrisii.**—The earliest plants may be pushed forward in gentle warmth if the flower buds are fairly well developed and the plants

are wanted in bloom. Do not hurry later plants that are not yet showing their flowers; if hurried in this stage the flower buds instead of coming forward are very liable to turn yellow. These plants are very subject to aphides, and should be destroyed directly they make their appearance.

**Hydrangeas.**—All the later plants that were rooted with buds in small pots should be placed into 5-inch without delay. Place the small plants down to their lowest leaves so that they are furnished to the base when their truss of bloom is developed. Do not hurry plants of *H. paniculata*, allow them to grow on steadily in the greenhouse.

**Spiræas.**—Lift and pot a number of these plants and bring them forward as may be required. It is a good plan to pot these plants for late flowering and then plunge them behind a north wall to retard them as much as possible. Allow *S. astilboides* to come into bloom under cool airy conditions. These plants will be valuable for the conservatory after the latest batches of *S. japonica* are over.

**Callas.**—Young plants in 3-inch pots may be placed into 5-inch, in which they will be thoroughly established before the time arrives for planting them out. These will make grand plants for early flowering. Some of the old and latest flowering plants can then be thrown away unless retained for the same purpose again. It is surprising over what a lengthened period of the year the blooms of this plant can be had by growing the plants in batches and subjecting them to different treatment.

**Azaleas.**—As these plants go out of bloom place them where they can enjoy warmth and moisture to start them into growth. Be careful that they do not become dry at their roots. Those intended for late flowering should be retarded in a structure with a north aspect. If plants cannot be given this accommodation ventilate the house in which they are growing abundantly, and apply a light shade during the hottest part of the day. Watch for thrips, and destroy them at once should any make their appearance. A weak solution of tobacco water, with 1 oz. of softsoap to the gallon, intermixed, and a piece of washing soda the size of a Cob nut. All plants that have flowered, and have fairly started into growth, may be potted if they need more root room. These plants do well in peat and coarse sand, or in leaf mould and fibry loam in equal proportions, with sand added. In either case the pots should be well drained, and the soil pressed firmly round the sides of the old ball. Water carefully for some time after potting, but syringe freely amongst the pots.

## THE BEE-KEEPER.

#### APIARIAN NOTES.

On the morning of March 20th the thermometer stood at 22°, and by 3 o'clock P.M. had only reached 40°. On the following four mornings it registered 26°, rising gradually to 62° throughout the day, all these days being calm and cloudless, a happy change to what we have been long accustomed to, the bees enjoying and taking advantage of it in vigorous style. The late Croci and numerous other garden flowers, together with the profuse bloom of the Tussilago and Willows, supplied large quantities of pollen and honey. It is many years since we experienced similar weather for so many days during the spring.

Bees with plenty of stores proceed with their internal economy unmindful of stern blasts and low temperatures, and I have no casualties to report amongst my stock. Even nuclei that contained very few bees in the autumn are healthy and working vigorously. Strong stocks are able to store surplus honey should we be favoured with several weeks' sunshine.

Early swarming will follow such conditions, and many stocks indicate they are well advanced. Although novelty has great attractions for some, it is not inappropriate to mention here that swarming is the most natural as well as the most profitable system of keeping bees; but it must be borne in mind that there are two forms of swarming—early and late. The former takes place only when previous arrangement and management have been well ordered, and it was indeed ludicrous to read from an author last year that it was early enough when past midsummer to commence feeding our bees so as to be profitable; and yet this author claims to have been the means of diffusing knowledge in practical bee-keeping amongst the million. It is an old adage, but a homely one, to "make hay while the sun shines." It is only through sunshine that bees can gather honey, so do all in your power to have them in number when it is likely to shine. Feed when bees require it, but withhold food when it is not needed.

Bees advance and decline more with the times of the year than from the earliness or lateness of the seasons or localities. Doubtless in sheltered places with a profuseness of flowers they come to the swarming point earlier than those in exposed situations, but the difference is due to the latter eating out their eggs and larvæ.

The case need not be discussed. Strict attention to good management of bees in the autumn very often makes up for all the difference in early or late swarms from hives in exposed or sheltered situations. Where very little honey is to be had until the end of July and beginning of August the swarming system is the most profitable as opposed to bees that are kept in early districts.

Adopt the best means to induce the stocks to swarm early, not later than the end of June, two swarms from each stock. By careful management the whole of these, stock and swarms, will be in excellent condition to gather honey by the beginning of August, equal to early non-swarms, and the prime swarm by the middle of July. The nuclei system should be started by the end of May, and then by the introduction of a youthful laying queen the best results follow. In early districts, but where the flora is of short duration, the doubling of swarms, or working on the non-swarms system, or the working of two or more into one, is the safest and surest course to pursue for a large yield, and the nuclei system is the best to prevent swarms when honey is wanted. If bee-keepers situated in early districts intend removing their bees to the Heather, the system of increase as advised above meets all the requirements of making the most at their disposal.

The extraordinary fine weather we are enjoying reminds us of the spring of 1840-41, and the fine summers that followed encourage us to prepare for the best, but we must always keep in view the fact—no bees, no honey.—A LANARKSHIRE BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

Knight, Clark & Co., Westham Nursery, Langney, Eastbourne.—*New and Choice Plants.*

John Smith, Royal Label Factory, Stratford-on-Avon.—*The Imperishable Stratford Labels.*

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Sulphate of Iron Added to Sewage (J. F. C.).**—Not only the Paris market gardeners, but the people of France use instead of waste their house slops, and produce the finest Pears in the world by its judicious application to the trees. Sulphate of iron prevents the loss of ammonia, and reduces the offensiveness of sewage to a minimum. About 1 lb. of the sulphate may be used to 10 gallons of sewage, and before use it should be diluted with not less than six times as much water as the disinfected sewage—say, 10 gallons to 70 gallons, at which it can be used for almost all kinds of vegetables and fruit trees; but it is frequently diluted to 100 gallons.

**Red Spider on Gooseberry Bushes (Tyne).**—We do not perceive that a solution of softsoap would take up more time than mixing Paris green in water and keeping it mixed. We do not advise the use of Paris green for this purpose. A solution of softsoap with a handful of sulphur stirred into three or four gallons is both safer and more effectual. One grower of Gooseberries finds clear lime water the cheapest preparation for destroying red spider. Lime should be used in fresh lumps. Pour water on them, stir well, then allow the water to get clear. If a film of lime settle at the bottom of the tub the lime water will be as strong as it can be made; if there is no sediment the lime water may not be strong enough.

**Chestnut Tree Partly Dying (J. H. J.).**—In the absence of other data than those you give we are unable to account for the tree dying on one side while the other is sound. If it arose from what you name the whole tree would be affected instead of half. The injury may have been caused by the burrowing of some larvæ in that part, so as to prevent the flowing of the sap, or be infected with some fungus which has gained access by a wound. We having seen some Elms lately that had several limbs destroyed by a Polyporus that has been admitted by

broken branches several feet above where the fruits of the fungus appeared, its mycelium having caused the death of the affected branches, the other parts being quite healthy. Possibly the side of the tree that is dying may have been struck by lightning, which would be easily determined by an experienced observer of Nature.

**Peat Moss Manure from a Poultry House (E. G.).**—1, The moss itself contains 1 per cent. more nitrogen than straw, and that from a fowl house only changed every three months will be more valuable than stable manure freed of the strawy portions. 2, It is best applied as a top-dressing, lightly pointed in, before cropping, if left on the surface greater part of its fertilising properties may be lost; a good spadeful is sufficient for a square yard, or a good handful to a yard of Potato row or Pea drill. 3, It is excellent for Roses and all flowering plants, applying a large handful in a circle 1 foot from the stem all round, and pointing it in very lightly with a fork. About a quart may be added to each half-bushel of soil used for potting soft-wooded plants, crumbling it to powder and mixing thoroughly.

**Peach Trees rather Gross (Inquirer).**—As your soil is sandy it would be desirable to mix one-fourth of clay marl with it, dried and pounded. This could only be done by lifting the trees, which you practise yearly, and firm the soil well—excellent practice, but not sufficient to check the tendency to luxuriance. The addition of marl or clay would give more substance to the wood and render less liquid feeding needful, as the soil would have more retentive power, as well as containing more mineral substances, to enhance the solidity and quality of the fruit. The manure—three parts bone meal, one part sulphate of potash, and one part sulphate of lime, is good for Peach trees, but it will not alter the character of your soil, which is too light and siliceous, and requires more body, with potash and lime. Those you will get in the clay marl, the best for stone fruits.

**Perpetual Carnation Cuttings Failing (H. L.).**—The best cuttings are about 3 inches long, detached with a heel, cut transversely or pared smooth, the lower pair of leaves being removed. The compost should consist of turfy loam, leaf soil, and sand in equal parts (mixed), and just moist, not wet. Insert each cutting in a thumb pot, using a little sand; press firmly, and plunge the pots two-thirds their depth in cocoa-fibre refuse in a frame kept close, and with a bottom heat of about 65° to 70°. In four days if bright, or a week if dull, the cuttings may be watered, giving enough to moisten the whole of the soil, leaving the lights off until the tops of the cuttings become quite dry, then replace the lights. Continue this procedure until the cuttings are rooted, then gradually inure them to the air of the house, and harden and shift into larger pots. The frequent dewing or sprinklings were the cause of the cuttings failing, as such practice is fatal to them.

**Potato Sets Required to Plant an Acre of Ground—Supply for a Family (S. L. A.).**—About 10 cwt. of average sets are required to plant an acre at ordinary distances—say, 27 inches from row to row and 15 inches in the rows, or 30 inches between the rows and 18 inches apart from set to set for strong growers; the quantities being about the same, as the sets of the latter are a little larger than those of medium growers. It is a mistake to plant small trashy tubers. The quantity of land for the supply of a family depends upon the culture, season, and produce, also the quantity of Potatoes consumed; hence your question is difficult to answer. We have known a family of twelve well supplied with the produce of half an acre, and another far from satisfied with the produce of an acre of ground. There is also a difference in families, some are for the most part juveniles, others mainly adults, and there is a great difference in the views of economy in the cooking, to say nothing of waste in different sorts of Potatoes, so that nothing more than an approximate estimate can be given—namely, one acre.

**Carrots Grubby (N. S. R.).**—The best plan would be to sow the ground intended for Carrots with Mustard now and allow it to grow to the flowering stage and then dig it in. If this were done so as to allow of Early Carrot seed being sown early in July you would have good Carrots for winter of a useful size, or the seed might be sown after early Potatoes, and the Carrots would escape the fly that is the cause probably of those being riddled with worms. The Mustard has been found efficient against wireworm, a frequent alleged affectation, but very seldom occurring in old gardens. Change of site, trenching, and stirring the ground in winter are good preparatory processes for Carrots. No kind of manure produces "a worm that destroys Carrots, Onions, &c.," but the frequent and excessive use of organic manures favour growth in the plants, which the parents of the "worms" like for their progeny. There can be no harm in using the remedy for wireworm—kainit. It may be applied now as a top-dressing, 1½ lb. being a sufficient dressing for the size of bed named. It may be had of any manure dealer.

**Bees and Fruit Blossom (St. Julien).**—Many growers of fruit keep bees in their orchards and gardens, both for their usefulness in the transference of pollen and for gathering and storing honey. You appear to be one of several who have been deterred from keeping bees because of their treatment as described by so-called advanced apiarists "appearing so intricate." Plain sound teaching is given in this Journal, and intricate methods of a deterrent character eschewed. You ask what a "Hallamshire Bee-keeper" has to say on the subject. He says, "Keep Punic bees in straw hives 30 inches deep by 12 inches in diameter, let them alone, and they will manage themselves." Bees in glass structures very often perish in trying to get out. Sweeping the extended blossoms lightly when dry with a plume of Pampas Grass, a

bunch of soft feathers, or a rabbit's tail (see Mr. Mowbray's remarks on page 251) suffices for pollen distribution. "A. H. B. K." also says as Punic bees have been in this country seven years persons who have had actual experience with them might say what they can against them. We are unable at present to publish a reply to your other question, but the matter is not urgent.

**Marechal Niel Rose under Glass (S. S.).**—For a week or more before the stems are cut down both the soil and atmosphere should be kept rather dry, also for a few days afterwards; then well syringe the Roses and house, and maintain a genial atmosphere, also afford adequate but not excessive moisture for the roots. As the growth extends the water supply must be increased, also the ventilation. The roof lights should not be removed at the end of May. Your removal of them led to the failure last year. Some of the best results in growing the Rose under glass are obtained under fixed sashes. The growths should reach the top of the house, and the wood and leaves become firm before the lights are removed—say in August. The growths must be kept clean. We have not before heard of the practice you suggest, and we are not in the least surprised that it did not prove satisfactory. Ten times more Marechal Niel Roses are grown under fixed roofs of glass than in structures from which the sashes are removed in late summer. If you cannot succeed without removing the lights by all means remove them, but not before the growths are strong and firm about harvest time.

**Names of Fruits.**—*Notice.*—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. *In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing.* The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (J. F. D.).—The large Apple is Hoary Morning, the small one Coo's Golden Drop. (B. D. K.).—Name not recognised, probably local.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (A. H.).—The fruiting form of the Hornbeam, *Carpinus Betulus*. The Apples shall be examined.

#### "FARMING."

QUITE delightful reading was the statement by "A Farmer's Wife" (page 211) of how one man takes up milk, Celery, and Potatoes, while others turn to Barley, horse breeding, and fruit growing—anything for which land, situation, or both appear suitable. Long have we striven to enforce the wisdom and safety of such common-sense practice, from a conviction that only by a wise modification of old routine, by the curtailment of one crop, the enlargement of another, the introduction of new crops, and a general but cautious change to meet the requirements of the times, can farmers grapple with and overcome their difficulties. All honour to such men! Nothing but praise do they deserve. Not to them do we refer when we point to those who persist in erroneous practices to their own serious loss, and yet who loudly complain of hard times, and pester the landlord or agent with periodical demands of rent reduction.

It is precisely because we are constantly meeting with such glaring examples of mismanagement that we are so outspoken. For example, our last week end was spent at a secluded Midland farmhouse. On this farm we have induced the tenant to make a snug lambing fold for the last two years, and he quite realises its full value. Walking over a neighbouring farm, we came upon some weakly twin lambs just born out upon a bleak pasture, across which swept a keen north-eastern blast, whose icy breath would make short work of them. No provision of shelter of any sort except the hedgerows was there, neither shepherd or farmer was visible, chance and luck evidently held sway upon that farm, and we were not surprised to come upon (in another meadow) about as wretched a lot of yearling cattle as we have ever met with. As we drove to the railway station next day we saw a considerable number of cattle and horses out upon very bare pasture, which they were nibbling just like so many mice. Prominent ribs and staring coats told the tale of hunger and deprivation all too plainly. Yet in that meadow there was a stack of hay uncut and enclosed by a stout barrier of bushes. Entirely did we agree with the outspoken opinion of our driver, that such brutes as the owner of the herd ought to be punished for cruelty to animals. They are punished indirectly by losses resultant from their mistaken economy. It is their cattle that so frequently realise less than was given for them twelve months ago. The whole thing is ridiculous and contemptible, and is altogether a matter apart from anything like "farming."

"A Farmer's Wife" must pardon us, but we cannot allow her dictum to pass unchallenged when she asserts that "animals do not like, and will not have silage." Clearly there are no prominent ribs, or staring coats of animals out of condition on that farm. So high fed are the whole of them that they will not eat

wholesome nutritious food for which less favoured animals positively fight. We have had both stockmen and shepherds who vowed that neither sheep nor cattle would eat silage, and if they did, it did them more harm than good. Such men had quickly to alter their views or be sent to the right about. To the lady it will suffice, we feel assured, if we venture to point out that the economical feeding of farm live stock has become a science, under whose beneficent guidance exact knowledge is acquired how to feed so as to obtain the best results at the lowest cost, a very different thing from the costly extremes of wasteful extravagance or equally wasteful parsimony.

In the matter of the comparative cost of ensilage, which we may explain indicates the process of making silage, and of hay-making, our fair critic has also been misled. Ensilage as now practised consists of mowing, carting, stacking, and pressing. There is no cutting up of the green fodder now that stacks have taken the place of silos. The process is simplicity itself, is much less expensive, and has none of the uncertainty of hay-making. In expense haymaking only bears anything approaching favourable comparison when the barometer is at set fair, and cloudless skies prevail day after day. In such weather hay-making is a delightful process. With grass mowed on one day, dried and stacked on the next, we pay very little heed to ensilage, and the hay made is of the highest quality provided the grass is mown at the right stage of growth. But, then, how seldom do we have such perfect summer weather? Certainly not during the last three or four years, and in unsettled weather not only does the cost mount up, but quality declines, sometimes so much that the hay is little better than litter.

We agree entirely with "A Farmer's Wife" that there are farmers and farmers. We live much among them, and it is precisely because we see so much that is wrong that we endeavour to point to better things. To the men of "new departures" we say heartily, Well done. To our critic we say, So entirely do we agree that there are two sides to every question, that I have endeavoured to show cause once more for the side which practice and reason prove to be the right one.

#### WORK ON THE HOME FARM.

The dry weather has been much in favour of late lambs, many of which came very weakly indeed, so that where they are out on bleak pastures many of them have but a brief existence, despite the absence of wet. Lambing is timed for the present month in the Midlands, and though it is so late in the season, flockmasters are well repaid for the provision of lambing folds, for March weather is proverbially fickle. Keep young calves confined to the hovels yet awhile, hoose is rampant among those which are let out in the open; in one instance we have found them suffering badly from this troublesome disease when kept in. This was owing to the filthy condition of the floor. The tenant has no arable land. Wheat straw now costs in that particular locality £4 per ton, he cannot afford to pay such a price, and the calves have to lie down upon a damp filthy floor. This is one of many an instance affording proof of the necessity which exists on dairy farms for just a few acres of arable land for the cultivation of a straw crop as well as some extra green crops. There is then a supply of home-grown corn as well as of straw either for food or fodder.

Home farmers should be on the alert to obtain bracken, sedges, or rushes for litter when either can be had. Mention is made of this because we recently saw a large quantity of bracken decaying in a wood near a home farm where straw was in use for litter. We know there are difficulties with gamekeepers about the cutting and collection of bracken, but these may generally be overcome by the exercise of a little tact and discretion.

Much of the Barley has been sown under favourable conditions on autumn-tilled land. Oats, too, have been sown so far as was possible, but we have a considerable breadth yet to sow after late folds. We pay little, if any, heed to popular ideas about what is termed Oat soil. For this crop it is more a question of manure than anything else—store the soil with fertility, procure good seed, and sow without minding about geological formation or other niceties of distinction. We have had Oat crops alike good in poor, thin, silicious soil and in very heavy land; on the thin soil it was possible to see outside the headlands where the manure had fallen short, straw with a tiny cluster of grains not more than 6 inches high, and out in the field the bulk of the crop 6 feet high. It is for this reason we say that no crop answers better, few so well, for plenty of manure as Oats.

## PRUDENCE IN EDUCATION: RURAL PROSPERITY.

PRUDENCE should be the motto of School Boards, of County Councils, of District Councils, and of Village Councils. Education should be to each individual only the means to the end. Education leading up to, and enabling the worker, be he farmer, market gardener, florist, or any other trade or employment, to digest technical knowledge as acquired through books and periodicals; as teaching and discussing his individual interests is real primary education.

Our leading statesmen have told us, and are continually telling us, that to bring the people back to the country we must provide the villagers with amusements for their evenings. So I suppose the piano and the secular choir, with all other harmless amusements, must be fostered. But the land agent will discover that imprudence will lead to extravagant ideas even in these small things, and "prudence" ought to be kept continually before the young people, be they of the family of the land agent, the farmer, the cottager, or the village tradesman.

We may be sure the hunting establishments will go on as long as it suits the farmer, and no longer. There is nothing to force the tenant farmer to join the hunt, or to keep a horse specially for his own riding to hounds, unless "prudence" tells him it suits his book in the long run. He may be one of the yeomanry, and he may find it to his advantage to breed a few horses of the lighter class. Look everywhere round, the inmates of our farmhouses, and for matter of that land agents, and most of the people who get anything of income or no income from the land, are less simple in their habits than their predecessors were. The easy communication with places away from home has partly caused the great change.

The light farmer's gig has replaced the rougher cart that helped to bring in the wife or daughter with the small produce of the homestead. Often the good old farmhouse with its ample dairy has had to give way to some ugly form of villa farmhouse, with parlour for the young ladies' piano, and so on.

If the mansion is let then let the owner reside in the neighbourhood. Land agents do not take the place of the landlord. I think Lord Winchelsea would abolish the land agent if possible. Very, very, difficult is the position we all know, yet something will have to be done, though it may be with as little unnecessary interference as can be devised. The land has its duties, and there should be a larger proportion of the income derived from land expended on the estate and in the neighbourhood than is now often the case. A hundred years ago things were very different as to expenditure of the income from landed estates.

Lastly, "prudence" tells us that no amount of education will ever supply the place of *practice*. Experience, with education by books and periodicals for assistants, is the only way to arrive at rural prosperity.—COTSWOLD.

#### REMARKS.

- 19th.—Cold, with unbroken sunshine, but slight fog after 3.30 P.M.  
 20th.—Bright sunshine throughout, sharp frost early, but much warmer in afternoon.  
 21st.—Sharp frost early, sun visible through fog all morning, shining brightly in afternoon, slightly foggy in evening.  
 22nd.—Slight, but very wet, fog early, bright sunshine from 11.30 A.M.  
 23rd.—More or less fog all the morning, bright sunshine after 1 P.M.  
 24th.—Bright sunshine throughout.  
 25th.—Unbroken sunshine.

A fine spring week with considerable range of temperature and some sharp frosts.—G. J. SYMONS.

### PRACTICAL HINTS ON MELON CULTURE.

TO the majority of those who have been engaged in the growth of Melons on an extensive scale this subject presents peculiar attractions, doubtless because they see in the rapid growth and handsome fruits a speedy return for the labour bestowed upon them. True, there are some who watch with intense interest and evident satisfaction the lingering growth of plants whose annual increase in size is of the most meagre description, but to the average man those forms of vegetation which create astonishment by the quickness of their growth give also the most gratifying results. To those who watch and tend them as their growth proceeds this pleasure is still further intensified, for it gives to the cultivator that inward satisfaction which causes him to regard as nought the labours which bring a reward so abundant and so good.

The time occupied in producing Melons from the sowing of the seed till the fruits are ready to cut varies considerably according to the seasons at which the sowings are made. The plants from seed sown the first week in January with good culture will afford ripe fruits sixteen weeks after. From sowings made in March two weeks less are required to reach a similar stage. During the summer months I have on several occasions cut large handsome fruits from plants raised from seed sown only twelve weeks previously; but to do this every advantage must be taken to secure high temperatures throughout the day by closing early and using the syringe freely.

Each seed ought to be sown in a separate pot, as the plants then grow sturdily from the first, and the risk of their receiving a check at an early stage of growth is thus avoided. If 3-inch pots are used, the only drainage necessary is a piece of crock placed over the bottom, and covered with a lump of turfy soil or moss; to either of these materials the roots quickly cling, and form good balls for placing into 6-inch pots, or for planting into the permanent beds. Care ought to be exercised in selecting the soil employed for sowing Melon seeds in, for I am firmly convinced that numbers of plants get into a stunted state in the earliest stages of their growth in consequence of the presence of minute insects in the soil. This undesirable state of affairs may easily be prevented if the compost is burned or thoroughly dried over a boiler at work before being used. Good loam, with a third of leaf soil added, is, I consider, the best for the purpose. Many employ loam without any additional material, but I find the roots work much more freely when leaf soil is added—this is an important consideration at that early stage. Press the soil moderately firm, and just cover the seed with it.

With the early sowing there is often a difficulty in providing a good position for the young plants until they are large enough to plant in their final positions. Bottom heat is of great advantage, and yet the plants ought also to be kept near the glass. These two conditions are not generally found in conjunction with each other, unless special means are taken to secure them. It is easy enough to find a suitable place for the pots containing the seeds where they will receive bottom heat, by placing them on the hot-water pipes or plunging them in propagating frames; but in either of these positions the seedlings are too far from the glass by the time the first pair of leaves are formed, consequently the stems become drawn at the outset; on the other hand, if at this stage they are taken from the bottom heat and placed on a shelf a check is

received, and but slow progress is made. This difficulty may be overcome to a certain extent by standing the pots on a board raised above the pipes at the front of a well heated house or pit; but when this course is adopted great care must be exercised to keep red spider at bay. The best of all plans is to make up a hotbed at one end of a house or pit, so that the young plants can be kept within a foot or 18 inches of the glass, and at the same time receive good bottom heat; sturdy yet quick growth is then obtained. When such a position is afforded them it is a good plan to shift the plants into 5 or 6-inch pots, and grow them there till the roots have reached the sides of the pot, when they are ready for setting in the beds.

I do not like the plan of using fermenting materials in Melon beds which are well supplied with pipes for affording bottom heat, because a strong heat is usually obtained to start with, and just at the time the plants require it most (when swelling their fruits) it is fast declining. This alone is a strong objection; others are the constant watching required to keep shoots from being cut with the tying material, as the bed sinks, and the great trouble experienced with woodlice whenever this practice is adopted. Unfortunately, however, the bottom heat pipes are frequently placed too low, so that it is absolutely necessary to devise some means of raising the plants considerably above them. Some recommend using large pieces of wood or clinkers, but if a layer of these a foot or more in thickness has to be employed very little heat reaches the soil in which the plants are growing. I find the best plan under the circumstances is to place a row of bricks on each side, add other layers until the required height is reached. Then lay cross pieces of boards, rough wood, or slate slabs, to form the foundation of the bed, and over this place another layer of birch, straw, or clinkers to prevent the soil from passing between the interstices when wood is used, or from becoming sodden when slate slabs are employed. If this plan is followed a chamber of heated air will be formed beneath the bed, which will maintain the soil at a more uniform temperature than it can be kept at if either of the previously mentioned methods are adopted. If a space from 9 inches to a foot in depth is left for the soil, ample root room will be afforded.

The distance apart at which the plants should be set ought to be determined by the length of rafter allowed for top growth. In many instances only a portion of the roof is available for covering with Melon shoots, on account of the upper parts of it being fitted with shelves devoted to the growth of plants in pots, which leaves only about 4 or 5 feet run of rafter for the Melon shoots. When such is the case 3 feet apart is about the right distance for the plants; but where another foot or two of roof space is at command the plants will succeed admirably if set from 6 inches to a foot nearer to each other.

In preparing the soil for Melons one often has a great variety of materials to deal with, for it is seldom that the ideal Melon soil can be obtained. A good turfy yellow loam, rather adhesive in texture, is generally regarded as the most suitable, and I doubt not that such a soil will with but little preparation produce fine Melons, but when this commodity is scarce I think it may with advantage be reserved for other purposes where soils more easily obtained may be rendered capable of producing equally good Melons, with a little extra attention in the way of preparation. Stiff loams without a particle of fibre will grow grand crops of Melons; so will garden soil of a heavy nature. The former should be stacked in a heap with layers of fresh horse droppings sprinkled with salt placed between layers of soil, these being a foot in thickness and the manure 3 inches. If this remains in the heap for twelve months it will require no other addition than one load of lime rubble to six of soil, with a little soot added. The garden soil if rich should have the same quantity of lime rubble and soot, and half a load of wood ashes; but if manure has not been recently added to it, one load of fresh horse droppings

to four of soil in addition to the other ingredients, will prove advantageous. Good turfy loam, such as that described in the first instance, will only need the addition of a sixth of manure and a sprinkling of soot. Whatever soil is employed should be placed in mounds on the bed twenty-four hours before planting is done, to enable every part of it to become thoroughly warm. Other remarks on the subject I must defer till another issue.—LABOR OMNIA VINCIT.

### CHASSELAS NAPOLEON GRAPE.

NOTICING the remarks about this *old* "new Grape" on page 249 of the *Journal of Horticulture*, I was induced to turn up and read the article I had missed on page 229, in which I find the history of the Grape is, I believe, correctly traced, so far, at least, as it is known and recorded in pomological works. It is somewhat curious, however, that in no British treatise on the Vine, not even the most recent and best (Mr. Barron's), nor in such a standard pomological work as Dr. Hogg's *Fruit Manual*, is the name "Chasselas Napoleon" mentioned, although the Grape has been fairly well known among Grape growers in this country by that name for fully thirty years, as stated in your articles. It came first under my notice in the year 1858 at Trentham, where it was then well grown under the name of "Chasselas Napoleon," and during that and several years following it was exhibited in collections of fruit by both Messrs. George Fleming and Archibald Henderson. Two Vines of it were grown—one in the Muscat houses and the other in a "Trentham Case" house. No artificial means were taken to "set" the berries; but they did set and swell as freely as the Muscats—of many names, if only one or two kinds—without the least extra attention. It may be stated that in the same Muscat house, and near to the Chasselas Napoleon, a Vine of Cannon Hall Muscat set its fruit admirably, and for several years produced splendid well-filled bunches, one of which exhibited at London by Mr. Fleming is still, I believe, the "record" bunch of that grand variety when "well grown," which unfortunately is seldom. At the same time and place Black Morocco set badly, although every means was tried, including artificial impregnation, to get it to behave better.

Referring to a list of the Vines grown at Trentham made by myself in the spring of 1859, I find the name of some Grapes which have since acquired much popularity, while others have almost or wholly disappeared. Among the former Alicante, Gros Colman, and Gros Maroc are prominent Grapes, while Caillaba, Chaptal, a good Chasselas type of Grape, Chasselas Rouge, Chasselas Noir, Chasselas Musque, Chasselas Vibert, Gros Romain, Gromier du Cantal (an immense bunch generally on strong Vines, with a good sized, showy, flame-coloured berry, of a refreshing, sweet, Muscadine flavour); Muscat de Juillet, Muscat de Saumur, Muscat St. Laurent, Muscat Ottonel, Sarbelle, and others of the small round Muscats, or more properly Frontignans, are now scarcely ever met with in private gardens, or seen at fruit exhibitions, although some of them, when well grown, possess excellent qualities for home supply and public competition.

Beside those mentioned, many other varieties of Grapes, including, of course, all the best Hamburgs and Muscats, were then grown at Trentham; Mr. Fleming being a keen collector, as well as a very successful grower and exhibitor of Grapes and other fruits. Many of the rarer varieties he had received in the "fifties" direct from the Continent, and others were supplied to him by Mr. Thomas Rivers of Sawbridgeworth, including, it is believed, the well-known Trentham Black, another really good Grape when well grown.

All the Grapes mentioned were in a bearing state at Trentham in 1859, and more or less "established," so that their merits and characteristics could be fairly seen and noted. Some have greatly exceeded expectations, notably Gros Colman, while others have fallen considerably short, and I regret to say "Chasselas Napoleon" must be included in the disappointing ones. I have a vivid recollection of its fine appearance at Trentham, and also in Worcestershire, in the first half of the "sixties," on a rich marly loam on which all kinds of fruit did well; but on a different soil, and with much better appliances, I have, after repeated trials, failed to grow it better than "indifferently passable." Hence, I have discarded it to make room for more useful Grapes, and from a tolerably wide knowledge I am inclined to think that my experience is that of most men who have tried their best to grow "Chasselas Napoleon" under the varying circumstances of different places.

This Grape occasionally appears still at exhibitions, showing how well it does in places where the natural elements suit it and good treatment is applied. It has been seen in fine condition at the Edinburgh Shows in recent years, I believe exhibited by

Mr. Ramsay, Fordell Gardens, Fife. It possibly may be grown at Trentham still, or in some of the numerous vineries in the West Midlands, which followed the Trentham example thirty years ago. The marvel is how experienced and business men have got so "mixed" over a simple affair; but as the name "Chasselas Napoleon" has apparently been overlooked to this period in our recognised standards they may be allowed the small excuse. In the "Fruit Manual," 5th edition, 1884, Dr. Hogg describes Panse Jaune in terms that might apply to Chasselas Napoleon, although not quite in accordance with my knowledge and experience of the latter Grape. The only synonym given is Grosse Panse, while under the Grape Bican he says:—"The Panse Jaune is frequently and erroneously called Bican on the Continent." Mr. Barron, in his "Vines and Vine Culture," says much the same under "Bican," giving Panse Jaune and Bican as synonyms of that variety, and adding that "the Panse Jaune is a large, coarse Grape, and is frequently called Bican on the Continent." Chasselas Napoleon and Bican in several exhibits at the Grape Show at the International Exhibition, Paris, October, 1889, were similar so far as the eye could judge. A large yellow-berried Grape exhibited at the same time under the name of Panse Jaune was not like the Chasselas Napoleon known to—AN OLD TRENTHAM MAN.

### THE WAYS OF DAFFODILS.

LAST year I kept a few potfuls of slowly forced plants for seed, and as the seed was not ready to gather until summer, by which time the leaves had died down, the bulbs were left in the pots, the latter being placed in a corner out of the way. About mid-winter I noticed signs of growth, and I had the pots with their contents placed in a warm house, at the same time giving a surfacing of light soil and manure. In due time flowers were produced, not so large as from imported bulbs, but certainly earlier than the latter could have been had. The sorts were Ornatus, Emperor, and Horsefieldi. The former was in 7-inch pots, and had some seventeen or eighteen flowers. Emperor was originally three large bulbs in 5-inch pots, and these produced six blooms, while Horsefieldi in 5-inch pots yielded ten flowers. To me the above was new in Daffodil culture.

I began cutting Sir Watkin out of doors on March 20th, a few days later than Ajax minor and earlier than Obvallaris. At the same time we have Sir Watkin with the flower stems 6 inches in height, and others just peeping through the ground. The earlier batch was forced last year, very early; some plants have been in the same position for three years, and the bulbs of latest were planted in November last. In the same way I have Ornatus at the present moment on the point of opening, along with others in various stages of growth; so also Horsefieldi and others. This, I think, is a most valuable feature in Daffodils. There is no plant that can be forced and suffer less. However, I invariably feed the forced plants right up to the time of the flowers opening. This is important; small pots, and high feeding. By the end of March early forced plants may be planted out, and if fairly well treated, may be again forced in two years thereafter.

In our borders are a few illustrations of the benefit of transplanting bulbs before they become crowded. There we have clumps of the same kinds, some with only two or three flowers showing, others with flowers from every strong growth. The difference arises solely from the latter having been transplanted, while the former had been overlooked.—N. B.

ORCHIDS AND ORCHID CULTURE.

WHEN it is stated that in a collection of Orchids of but very moderate dimensions there are representatives from the vast Continent of India, Burmah, Java, Borneo, New Guinea, Northern Australia, China, Japan, Madagascar, and other African islands, as well as the mainland, that Brazil, New Grenada, Guatemala, Peru, and Mexico are each supplying us with immense stores of their individual forms, it would, said Mr. W. Swan of Bystock Gardens, in a paper read recently before the Devon and Exeter Gardeners' Association, surely be unwise to prescribe a hard and fast line as to the methods of culture to be pursued, and expect in all cases certain and satisfactory results to be obtained. It is by no means absolutely necessary that houses should be at first specially erected,

as many kinds will grow and flower freely in an ordinary plant stove; but if once the culture is commenced with a desire and purpose continually to add to the collection, then it is much better that houses be set apart for the different classes, and so built that the needs of the various species are taken into due consideration.

Doubtless all were aware of the advantages of span-roof houses for most flowering plants, but it is not essential that all structures devoted to Orchid culture should be of this description. Half-span houses facing the south or south-west are capital structures for Cattleyas, Lælias, Dendrobiums, Aerides, and Vandas, while one of a similar form facing the north is very desirable for *Odontoglossums* and *Masdevallias*. This latter structure is much more necessary in the southern parts of the country than in the north, for if *Odontoglossums* are so situated that the greater portion of the summer sunshine falls on the glass roof the probability is that the atmosphere (though the house may be shaded with canvas blinds) will be much drier than is desirable for the well-being of the plants; and only by constantly damping the floor, entailing a considerable amount of labour and time, can an approach to a regular humidity in the state of the atmosphere be maintained. But a house facing north receives less of the sun's rays, and correspondingly a lower state of the temperature prevails.

The ventilation, too, would not need to be so excessive, which is often excessively draughty, and so when a good damping down is given morning and evening the air retains a sufficiency of moisture without any great variableness. It is very doubtful, too, if side lights are any advantage to Orchid houses, inasmuch as in summer, when the sun shines fiercely upon them, the state of the atmosphere about the plants is much too dry. To prevent this many fasten tiffany or paint summer cloud on the glass; and, again, in the winter the cold is so liable to catch the side that thick canvas or mats are fastened round to prevent the sudden and rapid lowering of the temperature.

If, then, instead of glass, brickwork were carried up to the gutters the houses would be cooler and moister in the summer, and in the winter drier and warmer. Again, do not allow cement to be spread on the inside walls of any Orchid house; this covering is of such a hard, dry nature that, holding no moisture, it cannot part with any. And in the winter the heated air from the pipes creeping up or along these surfaces soon become even more dry and hurtful. Simple brickwork, well whitewashed, will retain moisture, and be of considerable service in maintaining the uniformity of the atmospheric conditions.

The tanks for holding rain water should be outside, well bricked over, with a communication to a small dipping place inside; or, if the tanks should be built inside, they too, with the exception of a small place for dipping, should be covered, so that the whole of the surface under the stages would be simply soil, covered with ashes for appearance sake, or if clean fresh leaves can be obtained, a layer of these would be of considerable service. These surfaces during the spring and summer should often have a watering with liquid manure, and if a little guano and soot water can be obtained by all means use it.

Open tanks in the houses are a great evil, more especially when, as is often the case, they run the whole length of the centre and side stages. An idea is held by some that with such tanks evaporation will constantly be taking place, and a sufficiency of moisture be present to compensate for that which is lost through ventilation and the hot-water pipes. That the pipes will cause the air to become dry I readily admit, but that cold water in open tanks will throw off enough moisture I emphatically deny, and those who construct under this delusion make a fatal mistake. If the water is warmed by having a hot-water pipe passing through it, at times when the pipes are very hot too much evaporation will take place, and if there is no pipe at all the cold water becomes a condensing rather than an evaporating medium. Cold water under such conditions is as impervious as marble, and when still and without motion gives, comparatively speaking, nothing; but by abstracting the moisture already in the atmosphere the house becomes unduly arid, causes much harm, the plants suffer, while injurious insects increase at an alarming rate.

Houses specially erected, or those it is proposed to alter to the growing of Orchids, should have the side and centre stages built on the double shelf principle. By this I mean a lower shelf made so that the ashes or shingle may be spread on tiles or slates, and over this some 6 inches, another open lath stage on which to stand the plants. By keeping this lower shelf well watered much moisture is always present, and the open upper stage permits water rapidly to pass from the plants.

#### PHAIUS MACULATUS.

THIS handsome representative of a useful and popular genus is not quite so frequently met with as it might be. It has a double claim on our attention, as not only has it lovely flowers, but it is

one of the very few Orchids with variegated foliage, its dark green plicate leaves, which are nearly 2 feet in length, being freely spotted with yellow. The scapes spring from the base of the large ovate pseudo-bulbs, and are about 2 feet in height. These carry racemes of ten or twelve flowers rather closely arranged. The individual flowers are 2 or 3 inches across, of a soft yellow colour, except the middle lobe of the lip, which is heavily marked with reddish brown. *P. maculatus* is a native of Northern India and Japan, and was introduced in 1823.—A. B.

#### ODONTOGLOSSUM RUCKERIANUM SPLENDENS.

As will be seen by referring to the illustration (fig. 53), this variety is a decided improvement upon *O. Ruckerianum*, and when exhibited by Sir Trevor Lawrence, Bart., at the Drill Hall, on March 14th, the Orchid Committee of the Royal Horticultural Society adjudged it an award of merit. The sepals and petals are white with a faint rose tinge, and are densely spotted with

FIG. 53.—ODONTOGLOSSUM RUCKERIANUM SPLENDENS.

chocolate or reddish brown. The lip is pale yellow marked with a dark crimson blotch. The specimen exhibited bore an arching spike, on which there were fourteen fully developed flowers.

#### DENDROBIUM × BURFORDIENSE.

THERE is one invariable good quality that hybrids from *Dendrobium aureum* possess, and that is that the lip is comparatively spreading or reflexed, and consequently shows off to advantage. This is well seen in *D. × Ainsworthi*, *D. × Leechianum*, and *D. × splendidissimum*, all derived from *D. aureum* and *D. nobile*. The present hybrid was derived from *Linawianum* ♀ and *D. aureum* ♂, in the collection of Sir Trevor Lawrence, Bart., of Burford, Dorking, by Mr. W. H. White. It is a charming little thing, and may be compared to *D. × Dominicanum* (*D. nobile* ♀ × *D. Linawianum* ♂), except that the sepals and petals are more spreading and of a lighter shade, and the lip flatter, more reflexed, and with a smaller disc. The sepals and petals are pale blush, passing into light rose-pink near the apex, and the lip with a small maroon disc, a white zone round it, and a rose-pink tip. It is of free growth and very floriferous.—(*The Orchid Review*.)

#### NOTES FROM IRELAND.

WITH us March has been a month of uninterrupted sunshine, and Narcissi have opened very quickly. I fear that at the coming Spring Show of the Royal Horticultural Society in Dublin on April 20th they will be conspicuous by their absence. Last season they were a strong feature. The finest display of Narcissi in or near the Irish metropolis is at the College gardens, but coupled with the name of Burbidge, *cela va sans dire*. En route for these

happy hunting grounds some fine beds on Stephen's Green are very prominent; two large beds of Sir Watkin, about 500 to a bed, others of maximus, Emperor, and Horsefieldi, all true, supplied by a Dublin firm who need not blush at seeing their name on the labels.

At the College gardens they are now (March 29th) in full beauty, all a-growing, and how they do grow here! and all a-blowing, and how they do blow! Many of the inhabitants of the densely populated borders are also responding to the warmth. Very pretty are *Orobis vernus*, *Primula Harbinger*, and the unique dark College Garden Seedling; and very quaint is *Iris persica* on a low wall, with greenish white flowers. A mass of the small *doronicum* is intensely yellow. Nature is lavish with gold at this season. *Ranunculus montanus* peeps up with golden eyes from cushions of green, with gold below, and golden sunshine flooding everything; the *cœrulean* blue of *Ceanothus rigidus* clasping an old wall comes as a relief. But *Narcissi* is the menu to-day, and the *pièce de résistance* the long west border under a wall. Here the *chef* has large masses of Sir Watkin, Emperor, and Horsefieldi, great fat beauties with broad luxuriant foliage. Clumps of Sir Watkin and Horsefieldi are prominent in all parts of the gardens, and the isolated plants of the stately maximus, with its distinct and elegantly twisted foliage, are very fine. This maximus is peculiar to the gardens, not the ordinary type. In secluded parts are great gatherings of the clan *incomparabilis*, of which Sir Watkin is the chief.

One cannot pass without notice a huge scarlet *Rhododendron* in full flower, nor what was, to me, the most interesting plant seen to-day—viz., *Rhododendron Chamæcistus*, 2 inches high, bearing pale pink blossoms. Returning to *Narcissi*, the more delicate varieties are sheltered in a frame, *Triandrus*, *Corbularia*, and *Juncifolius*, some hung like tiny lamps on filaments of green, others with delicate ivory tubes. Quite unexpected we come on that *rara avis* Madame de Graafe; but Madame is coy, and but just rising from her bed. Oh, for a trowel and chance to burgle! Probably this enthusiastic young assistant who guides us round suspects nefarious thoughts, for he leads us back by devious paths till the heavy iron gate is reached, and closes with an ominous snap. Madame de Graafe safe inside, and safe outside in the chaos of a great city is—E. K.

### OVERCROWDED TOMATOES.

OVERCROWDING Tomatoes is a phase of "gardeners' greed" very many of us have been and probably still are troubled with. We begin by raising far more plants than are needed, and follow up this mistake—for a mistake it is to prepare many more than are wanted, especially when this means crowding in a young state—by planting them too thickly in their fruiting quarters. I hold that Tomatoes cannot well be grown too sturdily from the first, and also that starvation treatment does not pay. This sturdiness coupled with fairly luxuriant growth can only be maintained by allowing the plants plenty of room from first to last. When grown too thickly they shade and weaken each other, two plants very often not producing any more fruit than a single one would do occupying two-thirds of the room. Perhaps I am somewhat to blame in this overcrowding, but we live and learn, and it is my practice to avow any mistakes made when subsequent experience proves them to be such. The disease scare was responsible for many practices that otherwise would not have crept in, growing the plants rather thickly in comparatively poor solid soil being resorted to where it was not possible to save the foliage till such times as good crops were ripening. Starvation treatment, or what amounts to such, undoubtedly promotes a harder and more disease-resisting habit of growth, but it does not follow that this is to be recommended if there are any other ways of avoiding or defying disease. It would really appear that the diseases incidental to Tomatoes under glass are less virulent than formerly, a free use of fire heat and a good circulation of warm dry air being all that is necessary in most cases to ward off diseases. It is the more liberally treated plants, grossness, however, being guarded against, that give the best results.

If the plan of growing Tomatoes in comparatively poor, solid soil is being resorted to again this season, by market growers more especially, then there will still be some excuse for planting rather more thickly than I am about to recommend. Even in these cases, though, it may easily be overdone, especially where the plants are grown in the body of the house and trained uprightly. Placing the plants not much more than a foot asunder in rows 2 feet apart will not do. In all such cases it will be seen that it is the plants fringing the pathways that are much the most heavily cropped, those inside the rows unduly shading and weakening each other, the flowers dropping off or refusing to set fruit accordingly. Let

them be not less than 2 feet apart each way, and then there ought to be no great difficulty in setting large clusters of fruit from near the ground up to the roof, each plant carrying on an average of not less than 12 lbs. of fruit. The heaviest crops are usually taken from plants trained up the roof, and this plan of training is certainly the best that can be tried in small span-roofed structures or those, say, not more than 12 feet wide and proportionately high. In this case the plants are frequently put out 12 inches apart in a ridge of soil along each side or front of the house, but if it is intended to depart from the system lately much in vogue and to grow them more strongly, then they ought to be not less than 15 inches apart. A more serviceable class of span-roof house would be 14 feet wide, the same amount of hot-water piping being sufficient, this being a flow and return on each side. Here, again, a row of plants should be grown on each side and trained up the roof, and if they are disposed 18 inches apart it ought to be possible to take fairly heavy crops from two more rows of plants put out in the centre of the house, these being trained uprightly either with the aid of stakes or strings, the latter being much the cheapest method. These rows should be 2 feet apart, or else one on each side of central path, a distance of 18 inches dividing the plants in the rows. From the roof-trained plants an average of 18 lbs. of fruit should be taken, those less favourably situated in the centre of the house giving about 12 lbs. of fruit per plant.

When the plants have their roots principally or wholly confined to a narrow ridge of soil there is less likelihood of grossness prevailing; but it must also be remembered that they will require to be watered more frequently and fed more liberally than is the case when they are rooting in a bed of soil. There is nothing objectionable in planting in a level bed of soil, and if this is not excessively rich, and has been heavily trampled so as to make it extra firm, the Tomatoes will grow strongly without being over-luxuriant, and the watering pot or hose will not be required for use nearly so often. Soil that will grow garden vegetables, and especially Potatoes, well will usually answer equally satisfactorily in the case of Tomatoes, and under precisely the same conditions with respect to depth, drainage, and such like. There ought, however, to be one exception to this rule, solid or farmyard manure not being altogether suitable for Tomatoes. In addition to promoting grossness there is also the great risk of introducing the much to be dreaded eel worms with it, and for similar reasons an extensive use of decayed vegetable matter is to be avoided. Chemical and bone manures are most to be preferred, the latter, though slower in effect unless in a dissolved state, being the most lasting. Most horticultural sundriesmen supply manures very suitable for Tomatoes, and having tried many of them with results almost identical it would be manifestly unfair to give the preference to any one mixture. Soils also vary considerably in their character, and what may be most needed in one case would perhaps be almost wasted in another. A mixture that would hardly fail to suit the majority of soils consist of an equal weight, whether this be in pounds or hundredweights, each of superphosphate and kainit, adding sulphate of ammonia if the soil is somewhat clayey, and nitrate of soda if lighter in character, in quantity equal to one-quarter of the bulk of the two former; or to be plain, if 3 lbs. each of superphosphate and kainit is used add 1½ lb. either of sulphate of ammonia or nitrate of soda. This mixture should be applied at the rate of fully 1 lb. per square yard and thoroughly well mixed with the soil to a depth of not less than 12 inches. This I believe will be found a more economical way of using manure than by surface dressings, that is to say in dribbles, and the least likely to engender a too rank growth.

The plants being given the benefit of this fertile and fairly solid root run, and not allowed to form any surplus side shoots, will grow sturdily yet strongly, the lowest clusters of fruit are naturally most productive plants, reaching nearly or quite down to the ground. If any reader of the *Journal of Horticulture* can give particulars of practice superior to and at variance with what I have just described, and can advance good reasons for planting more thickly than I have advised in this article, he will confer a favour on myself beside many other readers.—W. IGGULDEN.

### SIXTY YEARS OF HORTICULTURAL PROGRESS. (1760—1820.)

(Concluded from page 326, vol. xxv.)

THOUGH the subject of forcing both fruits and vegetables was but imperfectly understood in the reign of George III., it was natural it should receive attention, because there were then no large supplies of either of these transmitted from the Continent, nor were means taken to obtain early crops in those western or southern parts of Britain where the weather promoted forward-

ness. There seems to have been an idea amongst some of our ancestors that forced fruit was very frequently lacking in the proper flavour; perhaps it might have been under some of the methods practised early in this century. By experiment and observation, however, our approved modern plans were slowly evolving themselves, and if the Georgian gardeners seemed sometimes to waste effort in trying first one way and then another, it was because they had not the means of getting information as to results which we now possess, so had to work out problems for themselves.

The forcing of Strawberries, when first attempted, was taken up energetically by several of the leading gardeners, such as M'Phail, Nicol, and Abercrombie. Commencing experiments were made by forcing the fruit in a pinery or Peach house; afterwards it became the practice to devote pits specially to this object, the plants, of course, being in pots. M'Phail advised that runners should be potted, in preparation, early in the season before, but many of the gardeners took up strong plants with their earth and then placed them at once in the forcing house or pit. Nicol advised a slow process, the heat being raised gradually, and Abercrombie preferred a rapid plan; he brought the pots from a cool frame where they had wintered into a warm house about the middle of March. Morgan it was, however, who showed that a succession could be had from November to June by right management. He started by forcing Alpines raised from seed, then he had Scarlets, and finished off with Pines. All gardeners used a rich loam for potting the plants, and kept the soil moderately moist.

There arose a good demand for early Kidney Beans towards the end of the reign of George III., and they were forced in Pine stoves or flued pits; the latter were often divided into partitions, so as to contain a succession of crops. Occasionally they were sown in a hotbed, and then planted out under handglasses. Abercrombie advised plenty of air and free watering, sowing in shallow soil, to earth them up gradually, but keeping down any runners. Nicol followed a method rather similar in forcing Peas, only he advised they should always be transplanted, whether grown in pits, or in the vinery, or Peach house, as was sometimes the practice. It was one of his beliefs that Peas in the open ground would be more prolific if they were transplanted.

Probably few gardeners now think it worth while to force Potatoes, but about 1812 much experimenting took place with the object of getting crops early in April; some grew them in pots placed in hothouses, and others planted them in frames 6 inches apart. Hogg, a well known market gardener, at a somewhat later period advised the use of an old Cucumber or Melon bed that had lost much of its heat, and his favourite early variety, obtained from Foxe's Yellow Potato, was called by his name. He raised a crop in seven weeks from the planting of the sets. One of his suggestions was, that "if frosts were sharp a better covering for all frames than matting was a layer of short hay."

Mushroom culture began to attract a good deal of notice, improvements being made on the old plan of growing them upon ridges of warm manure; also a sagacious gardener pointed out that as the plant was indigenous it might certainly be cultivated in ordinary soil during some part of the year and at the usual temperature, if desirable.

An impetus to Mushroom cultivation was given by the discovery of various ways of getting or making spawn, which soon became an article of sale in all large towns. Nicol discovered a process by which a bed of any required size might be formed into a mass of spawn by laying "courses" of stable manure, with earth between. In this way he obtained a crop about ten or twelve weeks after the bed was commenced, and it yielded longer than the beds ordinarily made. Then the manufacture of artificial spawn led to the discovery that it could be prepared for keeping in the form of bricks, such bricks retaining vitality several years if moisture was excluded. M'Phail advised growing Mushrooms in a lightly covered shed placed against the wall of a hothouse, and many put the spawn in boxes, pits, or baskets, which were used to fill up corners in pits or frames. A German method of culture was introduced by Oldacre. A peculiar compost was prepared, which was laid upon the shelves and bottom of a flued house constructed so as to afford a moderate steady heat, while but little light was admitted. Wales devised a plan for growing Mushrooms without manure, by warmth and moisture, and Williamson raised them economically in Cucumber and Melon beds. But the principal cultivators followed Abercrombie's advice, and watered moderately with tepid water, but did not grow them under a high and close temperature.

Propagation by inarching was the subject of much experiment early in this century. The origin of the practice is doubtful, but it had been occasionally tried as a kind of layering, the part of the shoot which it was wished to propagate being inserted into wood, or between wood and bark. It was presumed to have special

advantages in the case of plants which are reluctant to put forth roots. The two, whether in pots or in the open soil, were placed close together, and the layer or shoot which was to be bent or arched, was united to the stock, generally in the spring months. Having joined the parts they tied them closely, and then covered with clay or moss. It was customary to separate the shoot from the parent plant or tree in about five months, but twice or thrice that time was sometimes required. Professor Thouin, as the result of his inquiries about inarching, reported that gardeners knew thirty-seven different methods; practically, however, they were all varieties of two—viz., crown inarching and side inarching. The first of these was proved to be the best plan with young, hardy trees; the second was preferred for propagating delicate ones, or filling up blanks in branches. Knight made numerous experiments in inarching fruit trees, especially with the object of obtaining a supply of sap to enable a weak branch, by the help of a shoot from another part of the same tree, to swell and ripen its fruit. He thus got very fine fruit from Peaches and Nectarines where he would otherwise have had little or none. The Dutch tried inarching upon hedges of Hawthorn and Hornbeam, joining the shrubs together in a diamond or lozenge form, and leaving them attached. A funny experiment was the inarching of herbaceous plants, such as were of kindred species, the Cucumber upon the Melon, or the Tomato upon the Potato.

Possibly bulbous plants predominated in the gardens of seventy years ago, because some of this class were general favourites, and flowers now highly popular, the Rose, Dahlia, and Chrysanthemum for instance, only received a small share of notice. The Hyacinth rivalled the Tulip and the Narcissus, and even in the time of Miller there were reckoned to be 2000 kinds known in Holland, but a reduction took place, and a catalogue of 1820 enumerates about 300 only. It was the endeavour of our gardeners to produce fine double flowers, pyramidal in form, with large petals, and quite half the length of the stem. Dark colours were preferred to pale tints, provided they were distinct. Our English stock of Hyacinths was largely increased by their propagation, either from seeds or offsets. Many an amateur gardener was proud to exhibit to his friends a bed of choice Hyacinths, the result of much care and labour on his part. These beds were formed with a south aspect slightly elevated, and the English gardeners mostly used a compost for planting of leaf mould, cow manure, and sand; the Dutch added to this a little tanner's bark. Beds were planted in October or November, sandy earth placed round and over them, afterwards protection was given by hoops and mats. Maddock was very successful in getting fine seedlings, sowing in October or March, the boxes having equal parts of garden mould and sand. He left the plants untouched for three years in a moderately warm spot, then took them up in July. The Crown Imperial or Fritillary was an allied plant that was a favourite from its early blooming, and mostly increased by offsets as a quicker mode, and the common Fritillary, now seldom seen, was another favourite. There were numerous varieties.—J. R. S. C.

#### RHODODENDRONS.

I AGREE with "H. D." (page 250) in the main respecting the culture of this useful evergreen shrub, but I would like to add a caution for the benefit of those persons who have not had experience in any particular locality with the growth of Rhododendrons in the natural soil. I do not say they will not succeed in soil of a loamy character, but I know from experience that they will not exist here in the decayed turf obtainable on the place, which is generally termed loam.

"H. D." advises what to avoid—thus, "planting in soils containing a large percentage of lime or chalk." If he had substituted the word small for large I should have equally agreed with him. I know that Rhododendrons object very strongly to the smallest particle of chalk in the soil, this mineral I understand contains 75 per cent. of lime. The natural soil here is heavy and retentive of moisture, although it is not a wet soil in the sense of what a low-lying district would be; it is also much mixed with flint stones, which provides abundant percolating crevices for water in quantity. Chalk in its natural formation in most parts of the garden is not found within 3 feet of the surface, certainly not in that part where the Rhododendrons are growing. Chalk has been used as a surface dressing both for agricultural and horticultural purposes for many years before Rhododendrons were attempted to be grown. Although but small quantities have been used at a time the soil has become so impregnated with lime as to render it totally unfit for the growth of Rhododendrons even where nothing but the turf is employed.

As showing how small a quantity of chalk has been added to the soil in the form of a top-dressing, extending over so many years, it would be difficult to find any in solid form. When the beds for Rhododendrons were made here fourteen years since, with a view to economise peat, which is an expensive item in this part, some partly decayed turf that had been stripped off the old lawns was added to the extent of one-third. Where this came in contact with the roots of the Rhododendrons

they refused to enter it, and the plants made no progress at all. It was necessary to take them up and replace the compost entirely with peat. In addition we added partly decayed leaves and sand liberally. In a few years after I re-arranged the beds, removing the surplus plants to a recently added piece to the garden. Not having sufficient material to make up the beds of peat and leaves, I simply took out holes about 8 inches wider than the roots would occupy. The plants grew freely, but not grossly; the site being exposed, the growth was short-jointed, abundance of bloom being annually produced. As the roots neared the outside of the compost the length of shoot was reduced, the deep green of the leaves changed to a paler hue. As the roots afterwards came in contact with the natural soil growth ceased, and in some cases the plants died. Were it not for fear of occupying too much space other instances of failure could be adduced showing the unsuitableness of some soils to the growth of Rhododendrons.

I find manure fresh from the cowhouse excellent material for re-invigorating Rhododendrons that have somewhat exhausted the soil in which they are growing. By laying on the manure 3 inches thick, allowing it to gradually decay, the growth is much stimulated, the leaves quickly change colour, and the plants gradually improve. No time of year is better than the present for planting, provided, of course, attention in mulching and watering is given.

An edging of *Erica herbacea* gives, in my opinion, the best finish to a bed of Rhododendrons, especially if it is surrounded with grass. This low growing plant not only hides the soil, but gives a profusion of flower twice every year.—E. M., *Swanmore Park*.

### GRAFTING.

#### DOES THE WOOD OF THE SCION AND STOCK UNITE?

It has often occurred to me that the generally accepted theory that when grafting is performed the wood of the scion and stock never unite is not altogether satisfactory, and according to my own method of reasoning I have arrived at the conclusion that unless a complete union is effected between the outer wood cells as well as the bark, a permanently healthy and vigorous branch or tree cannot be produced by grafting, unless our ideas concerning the circulation of sap are at fault. If the crude sap ascends through the layers of wood how can it be conveyed from the stock to the scion when there is no connection between them? (except by means of the bark, through which the downward flow of sap passes). I am forwarding to 171, Fleet Street a portion of the stem of a Pear tree which has been sawn asunder through the grafted part. To me the union of wood as well as bark seems complete. A dark line shows clearly where the cut was made at grafting time. This appears to differ in texture from the wood parts around it; but the wood rings are perfect outside this dark line, and quite up to it. Is it not probable that after grafting is performed the soft woody substance immediately beneath the bark on both stock and scion unite, and form as it were a shell around the harder wood? After this has taken place the further development proceeds as in the case of ungrafted branches of trees—viz., each new layer of wood forms just under the bark, and completely encircles the older one. I shall be much obliged and interested to have your opinion of the matter, and also that of some of the numerous readers of the *Journal of Horticulture*.—H. DUNKIN, *Castle Gardens, Warwick*.

[The question of union between and circulation through the barks is an indifferent one, as these play a subordinate part and early disappear. The new wood and the new bark are developed from the *cambium* or sappy exudation between the junction of the stock and scion. The real union is effected by the alburnous layer or deposition of cellular tissue beneath the bark. There has been no union of the *heart-woods* of the stock and the scion in the example sent, or the grafting mark would have been obliterated during the course of eight or nine years; on the contrary, disunion of the wood is apparent, and the thin point of a penknife can be inserted between the wood face of the scion and that of the stock. The wood rings are perfect "outside the dark line," because this is new wood or superimposed growth, formed by annular deposits round the small original central core or stock which remains in its normal condition. These brief references to the specimens sent by our correspondent will enable those of our readers who may desire to do so to express their views on the general subject.]

### A CALL AT LAING'S.

LAING'S in Begonia time is a familiar place of call for those interested in flowers, but less so, doubtless, in the spring. The drawback to a special reputation for one class of plants is the fact that many persons form the impression that there cannot possibly be anything worth seeing when they are out of season. This is frequently a mistaken idea, and in no case more so than in that of the Forest Hill nurserymen, whose large and well-managed establishment can always boast of something to reward a visit. In the spring one of their best features are the Clivias, of which they make a speciality, and which they grow remarkably well. The collection is now in great beauty, and the increasing popularity of the plants is easily accounted for. Great have been the improvements in the plants of late years. They have been developed in size of bloom, size of truss and colour. It is true that the field of variation is a limited one, ranging from lemon to scarlet, and not embracing shades of purple and blue, but the former at least are not impossible of accomplishment, the lines being already materially deepened.

The following are a few of the best of the Clivias now in bloom or coming into flower:—Lord Wolverton, rich orange vermilion with enormous flowers, approaching the size of a small *Amaryllis*, and a dwarf grower; Stanstead Beauty, salmon orange with a nearly white throat, produces a fine truss, and is very dwarf and strong; *Purpurascens*, rich red with a purple suffusion, the deepest of all in colour, a vigorous grower; *Sulphurea*, pale sulphur; *Lemonæa*, lemon, a late variety that is just opening; Princess May, soft rosy salmon, a very large bloom, also a late variety; Bronze Beauty, bronze with lemon throat, distinct and good; Mrs. H. Broome, pale salmon rose, large flower; Lady Wolverton, brilliant salmon red, with very large reflexed flowers and a splendid truss, a very strong grower and in every way fine; John Laing, another splendid variety, orange scarlet with a fine truss, and a strong grower; Joseph Chamberlain, rich orange red, of fine foliage and habit; and Purity, clear salmon orange, a strong grower, of good habit and with fine foliage. The plants are all in perfect condition, and the fact of their doing so well under simple greenhouse treatment at Forest Hill should encourage amateurs and others to give them a trial. With bottom heat they can be flowered at Christmas if desired, and it is an easy matter to keep up a long succession of bloom. They do well in a compost of three parts loam and one peat when established, encouraging them with a more friable and porous medium while young. The plants from which suckers have been removed at Forest Hill are surrounded by a collar within the pot, and the space between this and the stem is filled with peat so as to encourage fresh growth. The plan is evidently a good one. With bottom heat the suckers, like Pines, emit roots quickly as soon as they feel the warmth; without this aid it is usually three years before small ones develop to a good flowering size, plants from seed requiring four years. Both as greenhouse and window plants the Clivias are worthy of attention, and it is worth while to note the length of time they will keep fresh in water, often six to seven weeks.

The Orchid department is growing rapidly, and the plants are in excellent condition. Amongst those in bloom may be noted a charming variety of *Odontoglossum asperum*, *Dendrobium Brymerianum* with its curiously fringed labellum, *Cypripedium hirsutissimum*, a fine variety of *Cymbidium Lowianum*, with a rich purplish chocolate lip; *Vanda tricolor superba*, one of the most beautiful varieties of that stately and beautiful plant; a fine form of *Dendrobium nobile*, named *Wallichianum*; and the beautiful *Odontoglossum primulinum giganteum*, with its large and beautifully rounded lip. This is a grand variety of a very charming Orchid. *Calanthe Sieboldi* is in bud.

Palms and Ferns are represented on an extensive scale, and so are Crotons and Dracenas. The collection of the Crotons is large, and the foliage full of fine colour. A few of the most noteworthy sorts are Beauty, Laingi, Flamingo, Magnificent, Madame E. Bergmann, Thompsoni, superba, gracillima, Hawkeri, Rodeckianus, ruberrimus, and Sunbeam. Of the Dracenas may be noted such fine sorts as *norwoodensis*, Barteti, Madame Bergmann, Lindenii, *Elegantissima*, and Louise. A case of *Bertolonias*, *Sonerilas*, &c., introduces some beautiful plants. Amongst the *Bertolonias* Madame Van Geert, Ed. Pynaert, Souvenir de Gand, and Louis Van Houtte were conspicuously beautiful. The same might be said of *Sonerila marmorata*, and another beautiful foliage plant too rarely seen is *Leea amabilis*.

The Forest Hill *Caladiums* are well known, and although it is at present somewhat early for them they are well worthy of inspection. Nowhere, probably, are the plants better managed, and their healthy and beautifully marked foliage awakens lively admiration. The varieties are too numerous for anything like a complete list to be given, but the following may be named as a few of the best:—L'Automne, Louis A. van Houtte, Mrs. Laing, Charlemagne, Baron Rothschild, John Laing, B. S. Williams, Mdme. Groult, Candidum, Chactas, and Mdme. Imbert Kœchlin. These are all both attractive and distinct.

More modest in growth, but not less beautiful in its way, is the charming little *Saxifraga sarmentosa tricolor superba* with its brightly tinted foliage. So beautiful a plant ought to be largely grown. A handsome *Begonia* named Arthur Malet, with leaves of burnished red, is also well worthy of attention.

In the stove one of the most striking objects is *Anthurium Laingi*, recently certificated. The spathe is white and of great size. It forms one of a large batch of Flamingo Flowers, which make a brilliant display in the portion of the structure devoted to them. *Plumbago capensis alba* is in bloom, and so is the not very familiar plant, *Gloneria jasminiflora*, which has small pure white flowers very much resembling *Bouvardias*. It is a free bloomer and undeniably attractive. *Sarracenas* are grown in goodly quantities, and so is *Dionæa muscipula*. Plants not too often met with are *Paulinia thalictrifolia* and *argentea*, which are curiously Fern-like in appearance, and do well under the same treatment as Ferns.

It is too early yet to say much about *Begonias*, but the thousands of young plants coming on in shallow boxes, the huge mounds of soil awaiting use, the large quantities of pots, and the extensive piece of ground in the nursery ready for the reception of the immense number of plants to be put out in the course of a few weeks are full of significance. Preparations for *Begonia* time are in full swing, and as the demand for the Forest Hill strains from all parts of the world goes on increasing the preliminaries for each successive season are heavier than those of its predecessor. This is satisfactory to the growers, and the fact that the foreign demand is so great will perhaps afford gratification to many who have no interest in the sale of the plants beyond that of patriotism.

**EVENTS OF THE WEEK.**—The Committees of the Royal Horticultural Society will meet on Tuesday, April 11th, at the Drill Hall, James Street, S.W., when a good display of Orchids and other flowers is expected. On the same day the Committee of the National Rose Society will hold a meeting at the Hotel Windsor, Victoria Street, and a gathering of the Horticultural Club also takes place. In addition there will be the customary auction sales.

— **THE WEATHER IN LONDON.**—As notified in another paragraph we have again to record a week of splendid weather. Clear, bright days have been prevalent, the sun being quite hot. Many fruit trees in the south are now in full bloom, and it is to be hoped that severe frosts will not set in, or the results will be disastrous.

— **WEATHER IN THE NORTH.**—Slight frosts occurred on the nights of the 26th and the 27th ult., and this morning (4th) we have  $4\frac{1}{2}^{\circ}$  recorded with hoar frost. On the whole, although cold winds have generally prevailed, the past week has been fine for the season. Saturday was a thorough April day. On the previous night a good deal of rain fell. More would now be welcome.—B. D., *S. Perthshire*.

— **ROYAL HORTICULTURAL SOCIETY.**—The next meeting will be held on Tuesday, April 11th, when the Fruit, Floral, Orchid, and Narcissus Committees will meet at noon in the Drill Hall, James Street, Victoria Street, Westminster. Mr. Everard F. im Thurn has promised a paper on "Orchid Life in Guiana." A large attendance of the outside public is expected.

— **NATIONAL AMATEUR GARDENERS' ASSOCIATION.**—A paper on "The Show and Alpine Auriculas: Their History and Culture," was read by Mr. James Douglas, Great Gearies, Ilford, at the monthly meeting of the above Association, which was held in the Memorial Hall, Farringdon Street, E.C., on Tuesday last. There was a large attendance, and Mr. H. A. Needs presided. After detailing the history of the Show and Alpine Auriculas, Mr. Douglas gave cultural directions, pointing out the items that were essential to success. A vote of thanks was accorded Mr. Douglas for his excellent essay.

— **GARDENING AND FORESTRY EXHIBITION AT EARL'S COURT.**—As previously announced in these pages, a series of special shows will be held in connection with this Exhibition during the forthcoming summer, and the dates have been arranged as follows:—May 13th (opening day), special flower show; May 18th and 19th, Orchids, &c.; June 28th, Roses, &c.; July 12th, Roses, &c.; July 26th and 27th, Carnations, Picotees, &c.; August 9th and 10th, flowering and foliage plants, &c.; August 23rd and 24th, Gladioli, &c.; September 13th and 14th, Dahlias and autumn flowers, &c.; September 27th, 28th, and 29th, hardy fruit, &c. A comprehensive schedule has been issued, and in addition to substantial money prizes a limited number of gold medals will be awarded to meritorious exhibits.

— **SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, MARCH, 1893.**—Mean temperature of month,  $45.1^{\circ}$ . Maximum on the 30th,  $67.3^{\circ}$ ; minimum on the 29th,  $20.4^{\circ}$ . Maximum in the sun on the 31st,  $116.2^{\circ}$ ; minimum on the grass on 29th,  $14.2^{\circ}$ . Mean temperature of the air at 9 A.M.,  $44.1^{\circ}$ ; mean temperature of the soil 1 foot deep,  $41.7^{\circ}$ . Nights below  $32^{\circ}$ , in shade, fourteen; on grass, twenty-two. Total duration of sunshine in month 164 hours, or 45 per cent. of possible duration. We had two sunless days. Total rainfall, 0.49 inch; rain fell on seven days. Average velocity of wind, 10.4 miles per hour; velocity exceeded 400 miles on six days—fell short of 100 miles on seven days. Approximate averages for March—Mean temperature,  $40.8^{\circ}$ ; sunshine, ninety-eight hours; rainfall, 1.73 inch. A bright and dry month; very warm days, but many frosty nights. The average daily maximum is considerably higher, and the daily range is larger than in any of the last seventeen years, but the mean temperature was a little higher in 1882. The rainfall is less than in any March during this period, the last fourteen days being rainless. The sunshine was more than we have had in any March or April since the record began in 1881, and more than the average amount for June, July, or August.—J. MALLENDER.

— **TITS AND FRUIT BUDS.**—Observing what Mr. Hiam says at page 255, I desire to say that I have done what he advises for between forty and fifty years; but I preferred to watch the movements of the birds, and examine the bushes and trees immediately after they were busy on them taking the buds.—W. T.

— **MESSRS. FOSTER & PEARSON, LIMITED.**—We are informed that the business lately carried on at Beeston, Notts, by Messrs. Foster and Pearson, the well-known horticultural builders and engineers, has been converted into a limited company, and that all accounts due to and owing by the late firm will be received and paid by the said Company, who will in future carry on the business under the style of Foster & Pearson, Limited.

— **PLANTING BULBS.**—The proper depth and manner of planting many of our flowers is a science not thoroughly understood. I have observed this in many things. One example will suffice to illustrate my meaning. As a test I planted several clumps of Scillas, the one half about  $2\frac{1}{2}$  inches, and the other about 4 inches deep. The latter are of a darker and brighter blue, so much so that they appear a different variety.—T.

— **SPIRÆAS.**—To the list given by Mr. Parrant (page 253) allow me to add *S. filipendula* fl.-pl. Growing about 15 inches high, and producing abundance of pure white double flowers, it is a most useful plant for the front of the herbaceous borders. *S. venusta*, sometimes named lobata or the Queen of the Prairie, is useful for the back of the herbaceous border, the deep Peach blossom colour of the panicle-clustered flowers form a pleasing contrast with other plants.—M.

— **MR. J. MUIR.**—Our old correspondent, Mr. J. Muir of Margam, S. Wales, although not contributing so much to the horticultural press as formerly, appears to be as active as ever in his locality. Last week he was appointed one of the overseers of the parish of Margam for the seventh year in succession. He was also returned unopposed as a guardian of the union in which he resides, and at the same time he contested a seat for the Margam Local Board, against two of the largest employers of labour in the district, with success. Perhaps Mr. Muir will become a bard in time.

— **SUNNY TORQUAY.**—That this favourite winter resort in Devonshire is favoured as regards warmth no one will doubt who has been there. I was very much surprised when there in November at the Chrysanthemum Show to see Tuberous Begonias, Zonal Pelargoniums, and blue Lobelias in full summer dress, and all within a few feet of the sea. Such was the case in the autumn of 1891 especially; we, here at Swanmore, having experienced  $6^{\circ}$  frost, and this is considered rather a favoured spot as regards the climate. These are only a few of the many plants to be there seen at that time of the year, but sufficient to show what a favoured place is Torquay.—E. M.

— **CHIONODOXA LUCILÆ FROM SEED.**—This hardy bulbous plant reproduces itself freely from seed in the open when the seed pods are allowed to ripen on the plants. We have a few bulbs planted in various parts of the rockery, and numerous other plants annually spring up, many of them several feet away from the original roots. As a rule, three years' growth is required to enable the bulbs to attain a size to produce flower spikes. The roots of this bulb enjoy a deep root run, and a fairly heavy soil seems to suit its growth, producing not only larger flower spikes but robust foliage.—E.

— **ROYAL HORTICULTURAL SOCIETY OF ABERDEEN.**—It will be recollected that shortly before the Royal Horticultural Society of Aberdeen held its Fête in the Central Park, Kittybrewster, in August last, Messrs. James Cocker & Sons raised an action against the office-bearers of the Society to have them ordained to receive certain exhibits of Roses and Dahlias which Messrs. Cocker had tendered, and which the Committee had refused. The action first came before Sheriff Robertson, who decided that on the strict construction of the Society's rules Messrs. Cocker were not entitled to exhibit, and he therefore dismissed the action. Messrs. Cocker appealed to the Sheriff-Principal, but the hearing of the appeal was delayed in consequence of a proposal having been made for a friendly settlement of the matters in dispute. Ultimately, however, the proposal made by Messrs. Cocker for a settlement was rejected by the Society, and the appeal was accordingly heard by Sheriff Smith at his last sitting. He has now given judgment recalling the interlocutor of August 15th, 1892, repelling the three first pleas in law for the defenders, and finding that it is now unnecessary to pronounce any order under the petition, finds the pursuer entitled to expenses.—(*Aberdeen Daily Free Press*.)

— **HYACINTHS AT WESTMINSTER.**—The Hyacinths in the beds facing the Houses of Parliament are just now making a charming display. The colours are admirably arranged, and the spikes of bloom are remarkably fine for bedding Hyacinths. It is not often that such a show of bloom may be seen in the centre of the metropolis so early in the year.

— **GARDENING APPOINTMENTS.**—Mr. Robert Palmer, for nineteen years gardener to the Right Hon. Lord Lyttleton (now Viscount Cobham), Hagley Hall Gardens, has retired, and has been succeeded by Mr. D. R. Dixon, gardener to J. Amphlett, Esq., Clent, for the past seventeen years. Mr. A. Gillett has been appointed head gardener to Laurance Hardy, Esq., M.P., Sandling Park, Hythe, Kent.

— **SHROPSHIRE HORTICULTURAL SOCIETY.**—The spring Show of this Society was held in the Music Hall, Shrewsbury, recently. In nearly all the classes there was a good entry and a splendid display of blooms. The collections were exceedingly fine, and in the two classes for bouquets and some others the competition was very keen. The Judges were Mr. Blair, Trentham, and Mr. Spinks, Birmingham.

— **WAKEFIELD PAXTON SOCIETY.**—At the recent meeting of the members of the above Society Mr. G. W. Fallas, one of the Honorary Secretaries, announced that Colonel Charlesworth, M.P., had given £5 towards the reduction of the debt on the Society's recreation ground in Pinderfields Road. Mr. MacPherson, who should have been the essayist, was unavoidably absent, and under the circumstances Mr. Hudson, gardener at Sandal Grange, kindly read an excellent lecture on "Spring Flowers," which Mr. William Paul, F.L.S., read before the Council of the Royal Horticultural Society some time ago.

— **WALKLEY AMATEUR FLORAL AND HORTICULTURAL SOCIETY.**—At the last meeting of the above Society, under the presidency of Mr. Cuckson, Mr. M. H. Willford, a very successful amateur plant grower, gave a useful and practical essay on "The Fuchsia." His treatment of the subject embraced a brief reference to the history of the Fuchsia, followed by cultural details, including propagation, potting, training, and feeding. He gave a selection of varieties, both double and single, and especially commended some of the best of the old varieties as worthy of cultivation. Mr. Willford received the thanks of the meeting for his interesting paper.—E. D. S.

— **STRAWBERRY CULTURE.**—At a recent meeting of the Edinburgh Horticultural Association a paper on the cultivation of the Strawberry was read by Mr. Mungo Temple, Carron House, of the berry as grown in the outside as well as when forced. Mr. Temple said the commercial value of the Strawberry at the present time might be gauged from the fact that in one day he had been informed the consignment of Strawberries to Glasgow was no less than 68 tons. The finest Strawberries he had ever seen were exhibited in the Music Hall in Edinburgh twenty-five years ago, and they were fruits of the variety known as Moffat's Duke of Edinburgh. On the cultivation of the berry the lecturer spoke on the various kinds of soil suitable for the different varieties, the necessity for air and sunshine, and the somewhat too frequent practice of allowing the plants to remain in the ground till both the soil and the plants were exhausted.

— **THE GOOSEBERRY CATERPILLAR.**—A correspondent, writing to the *Essex Standard*, says:—Those who, like myself, are lovers of that inviting though humble fruit, the Gooseberry, should now be anticipating the appearance of the caterpillar. A riddance of this pest is easily effected. Learning through the *Journal of Horticulture* that dusting the trees with a compound of lime and soot would destroy it, it struck me that syringing with soot water might prove equally effectual. Hence, during the month of April last, I syringed therewith thirty-three Gooseberry trees, which the caterpillar had threatened with destruction, twice a week for a fortnight only, the result proving its total disappearance for the entire season. My apprehensions as to the solution's effect on the foliage were groundless, and the fruit (Crown Bob) was never finer. One quart of soot will make 9 gallons of mixture, but as this ingredient is most rebellious against blending with plain water, the operator must not shirk extra exertions in his efforts to ensure a complete blend. The following is, perhaps, the best method of mixing: Put into a 2-gallon jar 1 quart of soot, and pour thereon about 2 quarts of boiling water, adding 1 ounce of common soda; shake thoroughly during two or three minutes and transfer to the liquid tub, after which give the jar two more vigorous rinsings, and make up to 9 gallons. I do not know how far it would be judicious to apply soot water to Rose trees for aphides, but purpose during the forthcoming season trying its effect with caution on three or four trees of no very great value.

— **IRISH DAFFODILS.**—The writer of an appreciative notice of the work of Mr. Baylor Hartland at Cork, in the *Irish Daily Independent*, observes:—"Of the climate Mr. Hartland speaks enthusiastically. For the cultivation of Daffodils and Narcissi it is the finest in the world, he says. After the climate, the next question of importance is the market and the facility for transit. Mr. Hartland is quite satisfied on these points. He can send all his flowers, packed in flat baskets, by the mid-day mail, from Cork, via Dublin and Holyhead, and they are on sale at Covent Garden and other centres at nine o'clock on the following morning. Mr. Hartland finds that, as a rule, he can beat the Scilly Islanders in the matter of quick transit to London. From Cork the time is only eighteen hours, while from the Scilly Islands it is sometimes two days."

— **SHAMROCKS FOR CHICAGO.**—The same writer goes on to say:—"The most unique order a florist ever received has just come to Mr. Hartland. It is for supplying 1000 pots of Shamrocks to the Irish village at Chicago. The order has come from Lady Aberdeen, who takes a deep interest in the flower-growing industry at Ardcairn, and has received from it many choice collections of blooms. The first consignment of the Shamrocks will be sent out on the 16th of April. Mr. James Scott, the Queenstown shipping agent, has made arrangements for having the Shamrocks sent on the deck of the mail steamers, and the pots will be watered at intervals during the voyage. This is the first time that a consignment of growing Shamrocks has been sent to America, and should the experiment succeed there is no reason why a thriving industry in exporting Shamrocks should not be established."

— **IRISH INDUSTRIES.**—Mr. Hartland is also described as an enthusiast in the matter of the revival of Irish industries, especially in the direction of making better use of the land than is done at present. With a fine climate and fair facilities for transit, he believes there is a fair opening for an extensive trade in flowers and certain species of fruit along the southern seaboard. But in order to make such an industry possible he is of the opinion that agricultural schools, supported by the State should be established in convenient places. Without these nothing very particular can be done in carrying the industry into rural districts where it is needed, and where it can be prosecuted to the best advantage. In pointing out how the industry might be established and worked to advantage, Mr. Hartland is doing splendid work at Ardcairn. Personally he is a typical Irishman, enthusiastic to a degree, and he enjoys great popularity in his own neighbourhood, where he gives a considerable amount of employment and spreads knowledge of horticulture which will be found of much advantage by-and-by, when the industry develops, as it seems destined to do.

— **THE CUCKOO.**—The very fine weather with which we have been favoured during the past three weeks probably accounts for the early appearance of the cuckoo, whose note was heard by several people in the woods near Maidstone on April 3rd. He usually arrives in this neighbourhood about April 14th, and I sincerely hope he may not have reason to wish he had waited another fortnight before visiting us, for on April 14th and 15th last year, after a spell of beautiful weather similar to that which we are now experiencing, came the snowstorm which was so disastrous in this part of the country. I learn through a friend that the cuckoo was heard on Good Friday near Bodmin, in Cornwall. On April 2nd I heard the little bird that in the New Forest is called the "cuckoo's messenger," and may be so called in other districts. It is here called the "snake bird," why I cannot tell. If I remember rightly it is one of the tree climbers, and is always heard just before the cuckoo.—C. R. F.

— **THE ARNOLD ARBORETUM.**—In the "Arnold Arboretum" Harvard University possesses, in the estimation of a writer in "The Century," the "finest tree museum in the world." Kew takes the lead among botanic gardens, but is not strong in its trees. The Arnold Arboretum, on the contrary, consists of 160 acres entirely given over to the cultivation of woody fibre, trees, shrubs, and climbers in all their infinite variety. It is not exactly a park, nor yet a garden, in spite of its fruits and flowers. It aims at showing trees as they grow naturally in woods, the different varieties being grouped together according to the botanical system of De Candolle—Magnolias first, because that tree has the most perfect flower; Conifers last, because in them the flower is most imperfect. In like manner the shrubs are conspicuously labelled, in a place set apart for them, where the soil is rich. It will interest those who are concerned in forestry to know that the young trees are raised from seed in the nurseries of the Arboretum, and in consequence of their careful cultivation and selection are reported to be singularly symmetrical, healthy, and promising.

— TESTIMONIAL TO MR. AND MRS. DODWELL.—Mr. and Mrs. Dodwell celebrate their golden wedding on the 20th of this month (April), and it is proposed by some of his old friends who have long watched the work done by Mr. Dodwell in the development of the 'Carnation, and who have very pleasing memories of the social meetings of the Carnation and Picotee Union at Oxford, to commemorate this auspicious event by the presentation of some suitable piece of plate, and it is felt that this object will have sympathy and support. It is proposed to limit individual subscriptions to 2s. 6d. or 5s., which may be sent direct to Mr. R. Sydenham, 190, Bristol Road, Birmingham, Treasurer of the fund.

— EASTER MONDAY IN LONDON.—Londoners made the most of the magnificent weather which prevailed on Monday last, the first Bank Holiday of the year. The parks, commons, and other open spaces of the metropolis were thronged as though all working London had decided to spend the day outdoors. It is difficult to determine the actual numbers who visited each place, but the crowd on Hampstead Heath was estimated at 150,000; 76,042 gained admission to the Crystal Palace; about 40,000 were at Kew Gardens; 30,000 went to Hampton Court; nearly 9000 visited Windsor Castle; 30,062 were admitted to the Zoo; 13,645 were at the South Kensington Museum; and 10,348 entered the Tower of London.

— RHODODENDRON NOBLEANUM AND ITS VARIETIES. — These Rhododendrons certainly deserve to be grown in far greater numbers than they are at present, for there is no hardy shrub in existence which produces such grand masses of showy flowers during February and March. At the time of writing (March 10th) we have half a dozen plants in full beauty, several trusses having begun to open their flowers three weeks ago, and although we have on several occasions since then experienced from 4° to 7° of frost the blooms have not been injured in the least. This is to a great extent accounted for by the fact that the plants occupy a very sheltered position, being protected by a very high wall on the north and east sides, and although they are 18 feet from the wall the great height of it gives them ample protection. I am confident, however, there are favourable situations in many gardens, where these useful spring flowers might be easily grown.—H. D.

— PRESENTATIONS TO HORTICULTURISTS.—Some interesting presentations in recognition of services rendered to the old Brighton Chrysanthemum Society were made at the recent meeting of the Brighton and Sussex New Horticultural and Mutual Improvement Society. Mr. J. Bunney was presented with a silver watchguard, a silver cruet-stand, and an illuminated testimonial; Mr. A. Fry with a silver cruet-stand and an illuminated testimonial; Mr. Rupert Miller with a gold watchguard and an illuminated testimonial; Mr. W. Richardson, Mr. J. Spottiswood, and Mr. J. Turner, each with a marble timepiece and an illuminated testimonial; and Mr. T. Thwaites with an illuminated testimonial and a set of Charles Dickens' works. Testimonials, beautifully illuminated with Chrysanthemums, and suitably inscribed, were also presented to Messrs. F. Collis, A. E. Golding, J. Hills, G. House, Mark Longhurst, George Miles, A. Netley, A. Scutt, and George Wickham, members of the old Committee.

— EARLY FLOWERS IN SCOTLAND.—A correspondent writes as follows to the *Edinburgh Evening Despatch*:—A walk through the Glen from Roslin to Polton on March 25th, showed the season to be an exceptionally early one in the matter of blossom. The catkins or "lamb's tails," as the country folks call them, of the Hazel are fast being superseded by those of the Alder, and the conspicuous flowers of the Ash have already begun to take the place of the dingy-looking bloom of the Elm. Many of our small spring flowers, too, are already in full bloom, some of them in great profusion. Banks and sheltered hedgerows have been bright for some time with the yellow flowers of the Coltsfoot and Lesser Celandine. The show of Anemones lends at present a distinctive charm to the woodland, their white flowers offering such a pleasing contrast to the glossy green leaves. The delicate blossoms of the Strawberry-leaved Cinquefoil are here and there to be met with. In some places the woods are covered with an undergrowth of Dog's Mercury. Two interesting little plants are also in bloom, the Golden Saxifrage and the Moschatel, the flowers of which somewhat resemble each other, although belonging to quite different families. Before reaching Polton the Bluebell-like flowers of the Periwinkle were seen early in monopolising the shady banks. These plants are all exceptionally early this season, and to see them in flower was an additional pleasure as well as an unexpected reward for the walk through this lovely glen.

— PLANT DISEASES AND BOTANY IN AMERICA.—As announced in the *Journal of Horticulture* for the 23rd ult., there are now as many as thirty-two botanical stations in the United States carried on by the various State Governments. The subject which receives most attention at these stations is that of the fungus and bacterial diseases of cultivated crops and fruit trees and their treatment and cure. A laboratory for the study of plant diseases has recently been fitted up in connection with the agricultural experiment station of the University of California at Berkeley. It has been arranged that a botanical survey of Nebraska shall be undertaken by the botanical seminar of the university of that State. The almost unknown flora of the north central portions of Idaho has recently been investigated by a commission acting under the auspices of the botanical division of the U.S. Department of Agriculture.

— RAINFALL IN SUSSEX.—The total rainfall for the past month at Abbots Leigh, Mid-Sussex, was 0.51 inch, being 1.57 inch below the average. The heaviest fall was 0.24 inch on the 1st. Rain fell on five days. This is the driest March in a fourteen years' record. The nearest approach to it was that of 1883, when the amount was 0.71 inch. The maximum temperature in the shade was 65° on 30th; minimum, 23° on 19th; mean maximum, 51.2°; mean minimum, 34.2°; mean temperature, 42.7°. A month more remarkable for the amount of bright sunshine than for the small amount of rain. Wild Cherries, Plums, Gooseberries, and Currants were in full bloom at the close of the month.—R. I.

— THE WEATHER IN MARCH.—The weather during the past month has been of an exceptional dry character. Bright sunny days with a total absence of east winds have prevailed, but the frosts at night have been of rather a severe nature. Rain fell upon six days during the whole month. Maximum mean any twenty-four hours was 0.17 on the 1st; minimum mean any twenty-four hours, 0.02 on the 6th; total during the whole month, 0.47, against 1.43 of 1892. Notwithstanding the very dry month of March, I have registered more rainfall by end of March, 1893, than I registered by the end of the three corresponding months of 1892. By the end of March, 1892, I had registered 3.90; end of March, 1893, I have registered 4.92.—E. WALLIS, *The Gardens, Hamels Park, Buntingford, Herts.*

— THE WEATHER—A REMARKABLE MONTH.—In the matter of weather the month that has just passed away has undoubtedly been one of the most highly favoured of recent times. In London the thermometer on the three last days of the month rose to between 67° and 68°. The latter reading has only been equalled once in the Marches of the past twenty years, while the mean of all the daily maxima observed in London during the month has had no parallel in any March of the same extended period. The sunshine totals for the entire month are not yet to hand, but from information already collected it is quite certain that in this respect also the March of 1893 will hold a very distinguished place. During the week ending Saturday last the bright sunshine registered over the United Kingdom generally amounted to 66 per cent. of its possible duration. Over the eastern, central, and southern parts of England the per-centage varied from 75 to 77, and in the south-west of England it reached 81, while in the Channel Islands, the percentage was as high as 91. The remaining feature of interest in our recent weather has been the general and marked deficiency of rainfall. The total amount for the whole month was less than half an inch over a considerable part of England and Wales, as well as in the east of Ireland, and less than three-quarters of an inch in the east of Scotland. For the majority of our meteorological stations the rainfall records do not extend back for more than twenty-seven years, and in some cases for only twenty-two years. An examination of the available data shows that over a considerable portion of England last month was the driest March on record, and at Roche's Point, where the total fall up to 8 A.M. yesterday, was only 0.11 inch, or smaller than at any other station from which returns are yet to hand. At Oxford, where rainfall has been recorded for a very long time past, the month was drier than any March for at least forty years past; and, as regards London, we must go back as far as the year 1854 to find a March with so small a rainfall. The London records for the past eighty years show that during this long period there have been only seven years with a March rainfall of less than half an inch. These were 1820, with a total of 0.33 inch, 1830 with 0.30 inch, 1840 with 0.32 inch, 1850 with 0.21 inch, 1852 with 0.26 inch, 1854 with 0.33 inch, and the present year with 0.39 inch. It is rather curious to observe that the first four cases of a very dry March followed each other at intervals of ten years. The only portion of the kingdom in which last month's rainfall amounted to anything like the average was the extreme north of Scotland.—(*Daily News.*)

— **THE EARLY SEASON.**—A correspondent writes :—"Although we have not yet seen any swallows or martins in this neighbourhood (Cheltenham), it may interest some of your readers to know that we heard the cuckoo for the first time on Saturday, the 25th ult. As to vegetation, everybody is of the same opinion, that we are here fully a month more forward than we have ever been before. Our Plum trees have been in flower as long ago as the 19th ult., and we have two Apple trees already in leaf. We have been gathering out-of-door Mushrooms on and off during the last fortnight—a most unusual occurrence, and one, my gardener says, unprecedented in these parts. As all the bush fruit and fruit trees are so forward, it will be a serious matter for gardeners if we have the usual April and May frosts."

— **EARLY FLOWERS.**—The season is so peculiar in forwardness that I venture to send a rough list of plants in bloom gathered March 29th, writes a correspondent to the *Standard*, in an ordinary walk of three miles. A few years ago there was skating on Good Friday (March 23rd), and deep snow on Easter Day (25th). Many more flowers might probably have been added had more research been given :—Wood Anemone, Small Celandine, Marsh Marigold, Helleborus foetidus and Helleborus viridis, Gorse, Ground Ivy, Dog Mercury, Colts-foot, Winter Heliotrope, Primrose, Cowslip, Daisy, Golden Saxifrage, Palm Willow, common Nut, Narcissus pseudo-Narcissus, Dog Violet, Sweet Violet, Hairy Violet, Barren Strawberry, Daphne laureola, Moschatel, Blackthorn, Draba verna, Whitlow Grass, Wood Sorrel, and Blue Speedwell.

— **WELSH WINE.**—The *Wine Trade Review* says : "We give in our present issue the result of several important sales of wines from private cellars. Some of the prices realised are noticeable, but the most interesting incident recorded is that at the sale at Birmingham of Mr. Lawson Tait's wines by Messrs. Ludlow, Roberts and Weller, four-and-half dozens of wine grown on the Marquis of Bute's Welsh estate were sold at the rate of 115s. per dozen. The wine is called the Castle Coch, and was produced in 1881. From the particulars given in the catalogue we learn that the vineyard on the Marquis of Bute's estate in the Taff Valley consists of about 3 acres of volcanic soil favourably situated for the growth of the Vine. It is added that the 1881 wines were exceptionally good, and all were secured by Mr. Lawson Tait. The Marquis's vineyard has been frequently mentioned, but we think it will be a surprise to most people to learn that the produce, even of a good year, is considered to be worth 115s. a dozen. If the soil is suitable for an extension of the vineyard, perhaps the result of the sale at Birmingham will hasten the commencement of the work."

— **PRUNUS TRILOBA.**—I can confidently recommend this *Prunus* as being one of the gems among hardy deciduous spring flowering shrubs. The flowers are produced from almost every joint of the previous year's growth, somewhat after the manner of *P. sinensis* flore-pleno. They are, however, of a beautiful soft rose colour in some instances, in others white tinted with rose, so exquisitely shaded as to be beyond description. These flowers are about the same size of those of the well-known *Prunus* already named, but unlike that variety only a portion of the flowers come double, a point not without due significance from an artistic point of view. We have a half-standard tree of this fine *Prunus* in the grounds here. It is about 5 feet in height, with a head almost as much in diameter, while the outline (without pruning) is perfectly symmetrical. At the present time each of the numerous twiggy shoots are completely studded with expanded or opening buds, the countless numbers of which combine to create a picture of delicate and pristine beauty which the inmates of an English hothouse or the flowering trees in foreign lands could not easily surpass.—H. DUNKIN, *Castle Gardens, Warwick*.

— **DEW ON PLANTS.**—The subject of dew appears to be still involved in some controversy. An experimental contribution to it has been recently made by Herr Wollny, who used plants in glazed pots with earth of varying moisture, some of these being allowed to radiate freely on favourable nights, while others were screened. The following, says "Nature," is a brief outline of Herr Wollny's views :—Dew depends partly on evaporation from the ground, partly on transpiration. It is at present doubtful whether it precipitates from the air share in it or not. A cloudy sky weakens the cooling process without stopping it wholly. With copious radiation, the temperature minimum is at the surface of the plant-covering (of the ground), and here the aqueous vapour rising from the warm ground is partly precipitated. With increase of the ground heat downward there is increase of the water brought up by the plants, which is given up as vapour and condensed. The more moisture there is in the ground, the more water is evaporated from the ground

and the plants. Dew formation is usually favoured by the larger number of stomata on the under surface of leaves than on the upper. On a given surface of ground the dew is more plentiful the stronger the plant organs above ground, and the closer the plant growth. The temperature of still air increases from the surface to a certain limit (at about 5 feet over grass it was sometimes 4° or 5° C. warmer than on the ground). In experiments with blotting paper, cotton wool, feathers, and asbestos, the first was much moistened, while the others showed dew in drops. Bodies of organic origin attract more moisture than those of mineral (a case of hygroscopic absorption). For vegetation, the author considers the benefit of dew but trifling. Of the whole annual precipitation at Munich dew only gave 3.23 per cent.

— **NITRATE OF SODA.**—In a paper on the Santa Isabel Nitrate Works, Toca Chile, read lately before the Scottish Institution of Engineers and Shipbuilders, and now printed in the Institution's Transactions, Mr. G. M. Hunter has something to say regarding the origin of "caliche," as nitrate of soda is called in its native state. Some contend that "caliche" is a marine deposit, others that it is an animal deposit, while others say it is a vegetable deposit. Mr. Hunter holds the first of these views. The coast of Chili has several times been disturbed and upheaved by volcanic agency, and he suggests that a large tract of sea was enclosed and heaved up to the present height of the nitrate region, and there formed an inland sea, which, after a lapse of time under a tropical sun, evaporated, leaving the salts to percolate and form the beds of nitrate. From the formation of the ground, showing depressions and ravines leading to the sea, it is evident that immense volumes of water at some remote period have passed through them. In proof of this, Mr. Hunter points out that no "caliche" is ever found in such places, the accepted opinion being that there has been a "wash out," as it is called. During a later period than that of the formation of the "caliche" great floods passed over the plains, as is shown by the deep tracks of rivers, and the smooth washed appearance of the surface. Such periodical floods are common in tropical, rainless regions, and would not call for special remark but from the fact that wherever these river tracks or washed surface appear no "caliche" can be found. This is so well known that even the workmen never attempt to search for it in such places. The only surface indication for the presence of "caliche" is rising ground covered with small black stones. The "caliche" in its native state is white, very compact and amorphous, not unlike rock salt, but when rich in iodine it assumes various colours, according to the composition and quality of the iodine it contains. For example, at times it contains masses of bright yellow, red, or blue, and again wholly composed of a dull black colour, in which state it requires an expert to distinguish it from costra or rock.—(Nature).

### MAGNOLIA CONSPICUA.

THE large white flowers produced by this deciduous tree are particularly handsome, and when seen in good condition invariably receive a large share of admiration. It should always be planted in a sheltered position, against a south wall if possible, because during the best of seasons we usually have a few sharp frosts while the flower buds are swelling, if not when the flowers are fully expanded. If in the latter stage 7° or 8° of frost quite spoil them, and blacken the unopened buds.

This *Magnolia* is one of those plants which well repay the trouble involved in affording a canvas protection during the flowering stage, even a coping board or stone does much towards protecting the upper portion of a tree. I have several times noticed fully expanded flowers within a foot of such protection quite uninjured, while those on other portions of a tree have been much disfigured. It is also a great advantage to keep the shoots as close to the wall as possible, because when frosty nights follow bright days radiation affords a considerable amount of warmth, and often prevents the flowers being injured by frost.

Where old trees have grown a considerable distance from the walls to which they are trained, the best time to set about the work of establishing growth nearer to it is as soon as the flowering period is over. The branches ought to be thinned freely, cutting out those which show signs of enfeeblement, and training those retained as near to the wall as possible. Numbers of strong shoots will then be produced during the growing season. A few of the strongest of these should be stopped, the others trained in thinly their whole length, removing all side shoots and growths made late in the season. Under this treatment numbers of shoots will be made, varying in length from 6 to 18 inches; every one of these will give a flower at the point, and the following year, if they are retained, instead of being spurred back, will produce sturdy growth a few inches in length at almost every joint. Each of these short growths will carry a bloom. In this way a perfect mass of flower is obtained. When this system is established the only pruning necessary after flowering is to cut out a few of the oldest shoots to make room for young ones to be laid in during the summer, always bearing in mind that these young shoots carry one flower the first season, and flower the whole length the second year.—H. DUNKIN.

## BAUHINIA CANDIDA.

THE Bauhinias, travellers assure us, are amongst the most lovely of tropical flowering plants. Owing, however, to the difficulty of inducing

is about 6 feet in height, and carries its flowers in clusters in the axils of the leaves at the points of the shoots. Some of the individual flowers measure nearly 4 inches across; they are pure white, delicately veined with green. The pale green leaves are two-lobed, and

FIG. 54.—BAUHINIA CANDIDA, *Reol*  
(*B. variegata*, *N.*)

them to flower satisfactorily under cultivation, we have but few opportunities of forming our own opinions upon their merits. Their beauty, as exemplified by a specimen of *B. candida*, now flowering in the Palm house at Kew, is certainly not overrated. This plant

nearly 3 inches across. This species is very rare in gardens, though it has been known for over a century. The Kew plant, from which our illustration (fig. 54) has been prepared, was raised from seed sent to Kew from Madras in 1883 by Sir M. E. Grant Duff.—A. B.

## CHRYSANTHEMUM ETOILE DE LYON.

WITH this I am sending you half a dozen blooms of Etoile de Lyon, cut from bush-trained plants grown for decorative purposes, and we find it one of the very best for late blooms. This experience may perhaps interest readers of the *Journal of Horticulture*.—JOHN LAMBERT, *Powis Castle Gardens*.

[The flowers were fresh and exceedingly fine for the time of year.]

## JUDGING CUT BLOOMS.

I AM pleased that "Sadoc" (page 202) is of my opinion, that if two flowers are put side by side the best is soon detected, and I do not see what injustice is done if, when side by side, a Jeanne Delaux is pitted against a Stanstead White. It is a decided advantage to the exhibitor who produces good flowers of difficult varieties to grow, like Mrs. Alpheus Hardy, Golden Dragon, or Thunberg. A practical judge can easily measure the comparison, and they have the advantage of being judged under the same light. This is not the case with stands placed long distances apart and in darker parts of the hall. "Sadoc" gives 4 points, we will say, to an Avalanche in stand A; when he finds this flower afterwards in another stand he may give it 4½. Can he accurately trust to his eye to measure this slight difference without having them near together?

I may not be quite clear where I say "Give a point for colour and freshness." The colour and freshness of individual blooms should, as stated by "Sadoc," be taken into consideration when measuring the comparison; but an exhibitor who tastefully arranges his colours and also includes difficult varieties like Refulgens, giving his stand a more pleasing and fresh appearance, should have a point for this over one that stages too many of all one colour although good flowers, and in accordance with the regulation of the schedule.

"Sadoc" asks me at about how many exhibitions do I find more than one bloom gaining six points? Six points is the highest I think, and I mentioned that number to explain my meaning. Judges are very shy of giving the maximum or six points to any flower meaning perfection, and to one show where it occurs I should say I find quite four lacking. If I had mentioned all those gaining five points, it means for the judge to carry his premier bloom to more. "Sadoc" is the first judge I am aware of who has confidence enough in his judgment to award a premier prize to a bloom without first lifting it out to compare it with one, or several we will say, only half a point less, when the points had been given to each a distance apart.—J. LAMBERT, *Powis Castle Gardens*.

## THE N.C.S. IMBROGLIO—MR. DEAN AND MR. TRINDER.

The following letters have been sent to us for publication.

Dogmersfield Gardens, Winchfield,  
April 3rd, 1893.

To the Editor.—Dear Sir, I have received a letter from Mr. Richard Dean concerning my letter which you kindly inserted in your last issue (page 258), and as it reflects on your correspondents, I venture to forward it to you, with a copy of my reply thereto.—I am, dear sir, yours truly, G. TRINDER.

## MR. DEAN TO MR. TRINDER.

National Chrysanthemum Society,  
Ranelagh Road, Ealing, London, W., March 31st, 1893.

Mr. G. Trinder, Dogmersfield Gardens, Winchfield. Sir,—In the *Journal of Horticulture* of March 30th appears an article, headed "The N.C.S. Committee versus Godfrey and others," and bearing your signature, in which you make reference to "recent discreditable proceedings connected with the Committee of N.C.S." and in the last paragraph of this article you allude once more to what you term "highly discreditable proceedings."

To many of the statements which have appeared in the *Journal of Horticulture* reflecting upon the National Chrysanthemum Society I have paid no attention. They have been confined to the columns of that paper; they were either anonymous or from writers not connected with the Society, and who could have no personal knowledge of what they were writing about, or from obscure persons gratifying merely personal feelings. It is different in your case. You are a member of the N.C.S.; you hold a deservedly high position in the estimation of your brother gardeners: you are at the head of one of the most important gardening establishments in the country, consequently any statement bearing your signature carries considerable weight with the gardening public. But your position also necessitates you should be very careful what statements affecting others you publicly make, and therefore you are bound to ascertain they are *bonâ fide* before you make public reference to them.

As it is impossible I can allow your statement to pass unnoticed, I am bound to bring it to the notice of my Committee. I have no hesitation in saying the officers and Committee of the N.C.S. are quite as honourable and high-minded as yourself, and they cannot permit themselves to be publicly charged by you with being associated with "discreditable proceedings" without calling upon you to justify your charges. I assume you have personal knowledge of certain facts to which you make allusion. I cannot imagine you would base your charges merely upon secondhand and probably interested statements. If you have a knowledge of this character

I am sure you will feel it to be your duty to set it forth fully, so that immediate steps may be taken to inquire into its correctness.

I need scarcely state that in charging a number of gentlemen who are largely known in the horticultural world with proceedings of a "discreditable character" you incur a very grave responsibility, which you must accept.

As I intend to bring your accusations before a meeting of the General Committee to be called at an early date, I shall be glad to have your reply at your earliest convenience.—I am, Sir, your obedient servant, RICHARD DEAN, *Secretary*.

## MR. TRINDER TO MR. DEAN.

Dogmersfield Gardens, Winchfield,  
April 3rd, 1893.

Mr. Richard Dean.—Sir,—Your letter to hand on Saturday evening last, and, in reply, I beg to say that the recent discreditable proceedings to which I refer in my letter to the *Journal of Horticulture* are those alluded to in the letters that have appeared in that paper—I mean those in connection with the member of the Floral Committee who voted against the lovely "Beauty of Exmouth" Chrysanthemum, and then offered to buy it; and also your own recent action in the election of a Chairman to that Committee. If you consider such conduct that of high-minded and honourable gentlemen, I beg to differ from you very considerably.

I think the majority of the readers of the *Journal of Horticulture* well know that the Editor is too honourable to allow "statements to appear from persons who could have no personal knowledge of what they were writing about, or from obscure persons merely gratifying personal feelings." You will please withdraw my name, for the present, as a member and subscriber to the N.C.S. I shall now forward your letter, and a copy of my reply thereto, to the Editor of the *Journal of Horticulture*.—I am, Sir, yours faithfully, G. TRINDER.

[Mr. Dean is in error in his allegation that our correspondents have "no personal knowledge of what they write about." Some of them know rather too much to please Mr. Dean, and withhold their names to prevent themselves being pestered with letters through the post. Mr. Ballantine's remark at the annual meeting with respect to the correspondence in these columns that "he was able to say an accession of members was distinctly traceable to that cause" had the effect of bringing several communications, and the methods Mr. Dean chooses to adopt have brought many more. We think we are right in suggesting that those gentlemen might have prevented the controversy if they wished; and at least they ought to be satisfied with the result of it—"a distinct accession of members." That statement is our justification for sustaining interest in the N.C.S.]

## FLORAL COMMITTEE OF THE N.C.S.

BUT for the letter of Mr. George Gordon in your last issue (page 258), I should not have again intervened in this controversy.

That gentleman appears to have discovered in my letter (page 240) an "inuendo" which certainly was not present to my mind when I penned the letter in question, and one which I do not think is presented even by the most strained construction of its contents. Surely it is permissible to credit Mr. Dean with the genuine intention to secure a chairman absolutely independent of late events without its being a necessary inference that the other nominee to the office was less independent or more implicated. When I desire to convey a meaning I do not resort to "inuendo." I say what I mean straight out, and assume the full responsibility for my statement.

In the present case it certainly never occurred to me to attribute to Mr. Gordon any association with the recent differences which have agitated the governing body of the N.C.S. I am glad to say that, save for the information gleaned from your columns, I am absolutely in ignorance who has and who has not been concerned in the contest, but the general impression left on my mind is that if there is one member, especially of the General Committee, who has not been drawn into the struggle it is Mr. Gordon.

My personal knowledge of the incidents of the late election is limited to one chance interview some two months ago, an interview lasting for two minutes covering the question "Would I accept the post of chairman if elected?" and the reply that "If, by so doing, I could be of use to the N.C.S. and help to restore peace within its borders, I would."

From that moment until I learned the result of the meeting of the General Committee I had no communication, direct or indirect, with Mr. Dean, or with any other officer of the Society, nor did I even know that there was to be any contest. Certainly, had I been aware that Mr. Gordon was to be proposed I should not have allowed my name to be brought forward, for I can imagine no one better qualified to fill the position of chairman. But the election had taken place, and for the reasons already stated I saw no sufficient reason to refuse the result and thereby throw upon the Society the inconvenience and delay attending the summoning of another meeting of the General Committee.

However, the incidents disclosed in your issue of the 16th ult., in my opinion, entitled me to disregard mere considerations of convenience, and these incidents, together with the additional light since thrown upon the present position of the Society, have decided me, under no possible circumstances to be connected with its Floral Committee either as Chairman or member.

One other point. If Mr. G. Trinder (page 258) will refer again to my letter he will see that it is not of the discussion of the "Godfrey" case that I, in common with others of your readers, am tired. It is with the acrimony and personal animus with which the discussion is carried on that we are weary. Those who have decided to keep the "Godfrey" case steadily before the Society until it shall have received a

fair and square adjudication upon its merits are fully within their rights, but cannot some of your correspondents manage to put forward their views as to this and other grievances without that bitterness of expression and those objectionable and unnecessary personal allusions which tend to alienate the sympathy of many who upon the main issues may not be disposed to differ very greatly from their views?

A good case is best served by a quiet statement.—CHARLES E. SHEA, *The Elms, Fooks Cray.*

[A great truth is conveyed in motto form in the last line of Mr. Shea's communication, and we shall be glad if it can be borne in mind by controversialists; at the same time we believe that some of our correspondents did not intend to be "bitter," but only forcible under provocation. We have refrained from publishing several letters as unsuitable in tone. It is just because many persons feel that the "Godfrey" case has not received "fair and square adjudication on its merits" that disquietude exists. Is it allowed to continue because it strengthens the Society?]

#### CHRYSANTHEMUMS AT EARLSWOOD.

ALTHOUGH in taking what was the only course open for an honourable man to take in relation to matters of a very unpleasant nature, Mr. W. Wells of Earlswood seems to have secured the enmity of certain members of the N.C.S.; yet do I think that his action merits the approbation of every honest man, and as evidence of this I may point to the fact that so far from suffering in any way in his business he has benefited. Being in his locality a few days since I thought I would look in and see how Mr. Wells was progressing, and how far the Chrysanthemum trade was developing. The jealousies and petty discords of the members of the N.C.S. are of no interest to me, but the progress of horticulture in any direction has much, and of that form of horticulture especially which does not feed on animosities and personalities, but rather upon the highest, purest, and most desirable of our aspirations. Well, I found at Earlswood house after house full as well could be of Chrysanthemums by tens of thousands in the rooted cutting stage, and many late ones yet to be rooted, whilst also the stocks of old plants would easily have furnished 20,000 more if needed. As it was, an immense number of young plants had been sent out both directly and through the trade, and because of the cool system of culture which prevails the plants are all stout and sturdy, and being well packed in moss suffer nothing in removal.

It was pleasant to learn that very large numbers of the finest new varieties are sought after by working-class growers, who wish to obtain the best so soon as their price will admit; the demand on Vivian Morel, for instance, yet the premier Japanese in cultivation, had been beyond precedent, and next year a few of the best of the past season will also be very popular, though none stand out of the general ruck in the same way that the one mentioned does. Mr. Wells, of course, keeps pace with the requirements of the times by securing stocks at once of all the best in cultivation, and to show that he is above personal prejudices, he speaks in the warmest terms of one dark variety now being put into commerce, W. Seward, as being the very finest of the class ever offered. His own sport from Vivian Morel, Mrs. W. R. Wells, pure white, and if set one of the finest whites in cultivation, has not received very courteous treatment; but Mr. Wells has great faith in it, although in putting it into commerce he has expressed his intention to refund a certain portion of the cost to purchasers should the sport not prove to be true. To my mind the fact that Vivian Morel will throw white flowers, and pink ones on the same plant shows that a fixed white sport is certain at some time or other. Tuxedor, old pot marigold orange, a beautiful and striking flower, and borne on very dwarf stocky plants, Mr. Wells regards as likely to be one of the gems of next season. However, time will show. The list for the present year handed to me of some 600 varieties is remarkable because of the almost exceeding abundance of new sorts, and the absence of what a few years since were high-class varieties. Such honours as the nomenclature of flowers give are usually very fleeting, and it would seem as if the average of Chrysanthemum immortality was about three years. Such is fame; who remembering this would have flowers named after them?

One of the Earlswood specialties is found in seedlings, for everybody must now raise a number of seedlings, and Mr. Wells produces a few thousands yearly from his own and imported seed. I saw boxes on shelves of recently sown seed, where the young plants, not unlike Parsley seedlings, were coming up thickly. I saw myriads of others from last year's seedlings, now rooted cuttings, saved from the best, and being tried again in that way. It would almost seem as if seedling raising would become to many a source of infinite trouble—a giant white elephant; but at Earlswood Mr. Wells has special strong partiality for single varieties, and these are very popular with ladies as cut flowers. Many of them are very beautiful; some singularly formed sorts, that the florist would reject, are often the varieties that sell freely. Amongst some of them Sarah Wells, violet pink; Purity, pure white; Mrs. Juikes, chocolate and gold; Alethia, deep crimson chestnut; Earlswood Terracotta, Crimson King, Miss Ida Bird, pure white; Jane Wells, flesh colour; Rose Queen, large rosy pink. These are but a few out of a long list of Earlswood and other seedlings.

In very few nurseries can a finer show be made in the autumn of pot Chrysanthemums than at Earlswood, for there is a huge and very long span-house, the which is at the blooming time cram full of plants. A portion of it is devoted to the growth of Niphetos Roses, tied up to stakes, and which bloom here on the strong loam in great profusion. The Chrysanthemums are stood amongst these plants in the autumn. The

other part of this large house is devoted to Tomatoes, the which it would seem are in good demand locally as anywhere else, for thousands of pounds of fruit are sold during the season. No doubt for all things grown on these Reigate slopes the pure air and abundant light and sunshine is exceedingly helpful. The district is one famous for its many Chrysanthemum growers, and to the credit of the Reigate men be it said that they do not grow for prizes so much as for love, for their local autumn show has done more for our garden charities in a few years than any other has, national or local.—D.

#### ROYAL HORTICULTURAL SOCIETY.

MARCH 28TH.

SCIENTIFIC COMMITTEE—Present: Dr. Müller (in the chair), Mr. McLachlan, Rev. W. Wilks, Mr. Wilson, Dr. Scott, and Rev. G. Henslow, Hon. Sec.

*The Antiquity of the Citron in Egypt.*—A communication was received from Dr. Bonavia, in which he referred to M. V. Loret's paper on this subject entitled *Le Cedratier dans l'Antiquité* (Paris, 1891). That author mentions several writers from 2 B.C. to 360 A.D., and states that it was cultivated in the fourth century A.D. in Upper Egypt (Coptic, "Ghitre"), while a Citron is said to have been found in a tomb of the twelfth century B.C. It is also figured on the temple of Thothmes III. at Karnak; fifteenth century B.C. From a drawing it would seem that even the "fingered Citron" might have been known. Dr. Bonavia discusses the probable source of the Citron in Egypt as being brought by traders through the Persian Gulf and Red Sea, for he thinks that all varieties originated in South China and spread westwards. The value of the Citron was supposed to be purely medicinal by the ancients, and M. Loret alludes to one use, namely, for affections of the spleen, the true value of which Dr. Bonavia corroborates.

*Peridermium Strobi.*—Mr. Plowright sent specimens of this fungus with the following observations:—"Last July I found in the garden of Mr. C. E. Boyes, at Oakwood House, Tottenham, that the Currant bushes were affected with *Cronartium ribicola*, specimens of which were sent to the Scientific Committee, as this fungus had not previously been recorded in Great Britain. In the same garden were some young trees of *Pinus Strobus*, which were roughly trimmed so as to form a screen or hedge. On these trees must have occurred the æcidiospores of the *Cronartium* at some season of the year, Prof. Klebalm, of Bremen, having shown that these form the life cycle of this fungus. On March 19th of this year I visited Oakwood House, and was pleased to find the *Peridermium* in perfection. It will be noticed on the specimens sent that the mycelium of *Peridermium* is perennial, causing a certain amount of hypertrophy in the affected branches, forming generally a fusiform enlargement of the twig. The peripheral extremity of the branch suffers somewhat at first, and eventually dies. The mycelium of the *Cronartium* is annual. With the heteroecious *Uredineæ* sometimes the æcidiospores have permanent mycelia as is the case here, at other times the mycelium of the teleutospores is thus endowed as with the *gymnosporangia*."

*Ustilago on Psamma arenaria.*—"The so-called *U. hypodites* which occurs on this Grass is doubtless a distinct species. It is not common in Great Britain and appears only to have been found upon the east coast. The specimens sent herewith are interesting as having been produced by a root which was transplanted from the sea coast three years ago into a town garden, and which still produces diseased stems. One of the specimens shows a curious distortion, consisting of a twisting of the stem within the sheath. This may be due to the fungus, although in the majority of cases this condition does not occur."

*Polyanthus Blue Primrose.*—Mr. Wilson exhibited a seedling from Oakwood Blue Primrose, with a very large flower, a Marianne North (pale blue), and a plum-blue *Polyanthus*, it being the first occasion of this strain assuming the umbellate form.

*Cucumber Roots Diseased.*—Mr. Hurnard of Hingham sent a specimen, which appeared to be attacked by the common "eel worm." It was referred to Mr. McLachlan for further examination.

*Fasciated Cotoneaster.*—A specimen of this common malformation was sent by Mrs. A. Stuart of Edinburgh. Mr. Henslow had observed a bush in a garden at Penmaenmaur, on which nearly every branch was fasciated.

*Tuberculated Stem of Ailanthus glandulosus.*—Mr. Wilson brought a specimen having a tuberculated structure, 6 inches broad and 3 inches deep, issuing from around the junction of stem and root. The knob-like tubercles consisted of "embryo buds" agglomerated together. What the original cause might have been which produced the hypertrophied condition, with arrest of axial growth of the buds, it was impossible to say.

*Dimorphic Aralias.*—Mr. Tidmarsh, Curator of the Botanic Gardens, Grahamstown, sent some foliage of two species of *Aralia*, which, he observes, would certainly be regarded as four species had he not known the plants from cuttings upwards. The leaves of *A. Veitchii* when growing in a poor soil are about 4 inches long, and one-fifth of an inch wide. Those sent were grown in a poor soil under glass. The leaves of the same species planted out in a mass of fresh compost in a hothouse, with a moist atmosphere, and at a temperature of 60° to 90° F., were 5 inches long, and 1½ broad. Hence, while the former are linear, the latter are broadly lanceolate and tapering at the base. He also sent leaves of *A. reticulata*, which were upwards of 2 feet in length and 6 inches in breadth. The plant was 10 feet high, planted in the open on the

banks of a stream, but too far above the water to be benefited much by it. It was under Willows, which to some extent protected the foliage from the frosts of several degrees experienced at Grahamstown. Mr. Tidmarsh added that he had no inside plants of this last species with the narrow-leaved foliage. He remarks, "We can propagate from cuttings of the narrow-leaved form, but fail to do so with the large-leaved form. This plant behaves in a similar manner to *Araucaria excelsa*; the young growth of which, while still possessing the narrow Juniper-like leaf, will strike from cuttings, but we cannot succeed with small side-shoots from an old trunk, these latter shoots being furnished with a thick bark and stout foliage of the mature tree." Mr. Tidmarsh raises the question whether the larger leaves of these *Aralias* may not be the naturally mature form, and the smaller foliage characteristic of the young stage, as with the *Eucalyptus*. An examination of the epidermides of the leaves sent shows that the number of cells in the same area of the broad-leaved form is to that of the narrow leaved as fifty-five to thirty-eight (upper), and as forty-four to thirty-six (lower), so that this element does not support Mr. Tidmarsh's view, inasmuch as the cells, being smaller on the larger leaf, would *per se* suggest its being the younger.

### PANSIES AND VIOLAS UNDER GLASS.

I HAVE seen during the early part of March in some gardens Pansies and Violas being almost ruined by being kept shut up too closely in frames, the plants drawn and weakly-looking, and too tender for planting out and encountering cold winds and spring frosts. I therefore warn readers against this practice. It is a mistake to treat Pansies and Violas so tenderly, and leads to disappointments. Here in Birmingham, which does not enjoy the best of atmospheres, I could show robust and healthy plants of both grown in frames in my town garden, and they have no protection but lights over them in bad weather, but with air admitted. For some time the lights have been off altogether, excepting when cold east winds have prevailed.

Planting out should be done as soon as possible when the plants are well hardened; the soil having been prepared, then plant rather deeply and firmly. If the growth above ground is long, peg it down so as to secure it from injury by wind. In advising planting out at once, I have in my mind the possession of strong, well rooted plants, which can be removed with some earth about the roots.

Purchasers from florists should insist on having only strong, well-rooted plants sent, each rolled up in a piece of paper securely, with damp moss about the roots, not sent, as many are, several in a box, scarcely rooted, and arriving in a dry state. Such plants should not be planted out at once, but be nursed in a frame or small pots until they can be put out with safety. Weakly plants do not come into good bloom until July, when the weather is generally very trying to Pansies. I am assisting a friend in the midlands who does a very great business in Pansies in getting away his orders, and from 3000 to 4000 plants pass through my hands each week, each done up separately, well rooted, strong stuff, rejecting any which are badly rooted and not likely to please.—W. DEAN.

As a southerner, I should like to add my testimony to that of Mr. W. Dean (page 156) on this matter. After reading the remarks on "Florists' Flowers" by "D., Deal," I came to the conclusion that the plants are coddled too much. I have a few hundred plants, and I have not lost six other than by the havoc of moles. During the cold weather the moles burrowed through the frame and turned out a few plants. Apart from this calamity I do not think I have any losses to record.

My plants are protected in small frames made of half-inch match-board, and the lights are old windows pulled out of dwelling houses. They neither fit into grooves or lay flat on the framework, and this is the only covering or protection the plants have had all winter. During severe weather the soil and plants were frozen very hard. After the long spell of frost a little loose litter was thrown over the lights till the bed was properly thawed. The cracks in the boards are numerous and wide, and every current of air that blows goes right through the frame, and this I credit with assisting to keeping my plants healthy. Not a sign of damping is to be seen; the plants remained at a standstill all the winter, so that the mildew as well as damping is unknown. Now the plants are commencing to grow a little they will, perhaps, be more susceptible to these evils. The lights have been left off the frame for weeks together, and the plants have only been watered by the rain. The protection is afforded to provide against extremes of weather, not to resist the cold. I consider March the most trying month for Pansy growers. A couple of days with an east wind will do more damage than a whole winter.

I quite endorse Mr. Dean's remarks anent early planting. If there is a secret in Pansy growing it is in planting as early as possible. When we get the plants out early in March it is seldom we are troubled with that mysterious "going off" too prevalent in many gardens. Last season I lost very few plants where early planting had been followed, but I lost many seedlings through late planting. I think last summer was a fair test too in this respect. It is only the fact that my soil is exceedingly heavy and retentive that has made me abstain from planting so long. The plants are easy to shelter from the bitter east winds if 6-inch pots are employed to cover them. They can be placed over the plants each night, and in severe weather remain over them for a day or two without doing any appreciable damage.—JAS. B. RIDING.

### ROSE SHOW FIXTURES IN 1893.

- June 20th (Tuesday).—Westminster (N.R.S).  
 „ 28th (Wednesday).—Clifton,\* Richmond (Surrey), and Windsor.  
 „ 29th (Thursday).—Eltham.  
 July 1st (Saturday).—Crystal Palace (N.R.S.).  
 „ 4th (Tuesday).—Bagshot, Canterbury, Diss, and Gloucester.  
 „ 5th (Wednesday).—Croydon, Ealing, Hereford, and Lee.\*  
 „ 6th (Thursday).—Bath, Farningham, Norwich, and Sutton.  
 „ 7th (Friday).—Hitchin.  
 „ 8th (Saturday).—Reigate.  
 „ 11th (Tuesday).—Wolverhampton.†  
 „ 12th (Wednesday).—Tunbridge Wells.  
 „ 13th (Thursday).—Worksop (N.R.S.), Harleston, and Woodbridge.  
 „ 14th (Friday).—Helensburgh.  
 „ 15th (Saturday).—New Brighton.  
 „ 20th (Thursday).—Trentham.  
 „ 22nd (Saturday).—Manchester.  
 „ 27th (Thursday).—Halifax, and Southwell.

\* Shows lasting two days.

† Shows lasting three days.

I shall be glad to receive the dates of any Rose Shows not mentioned above for publication in my next list of fixtures, which will be issued early in May.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

### EARLY ROSES.

WHILST strolling in the neighbourhood of Enfield on Easter Monday I noticed a Gloire de Dijon Rose growing on a wall facing south, and some of the young shoots of the current year's growth were several inches in length, the flower buds being discernible. I do not know if Roses generally are so early this year, and on this point perhaps some of your numerous readers can enlighten me. It would also be interesting to have a record over series of years as to the dates when the first Roses expanded in the open air. Certainly there are prospects at present of our having outdoor Roses by the end of April if frosts do not check their career.—SUBURBAN.

### THE PARENTAGE OF ROSES.

IN my former article (page 214) upon this interesting subject, I spoke chiefly of the origin of Hybrid Perpetuals, though I had some incidental allusion to the beautiful modern Noisettes and Teas. Among the most delicately graceful of these is Belle Lyonnaise, which owes its characteristics to the Gloire de Dijon, and of which I may add there is an absolutely perfect and most exquisitely coloured illustration in Mr. William Paul's book, entitled "The Rose Garden," perhaps the most comprehensive work existing on Rose cultivation. There also will be found a very fascinating artistic delineation by an eminent artist of the Maréchal Niel, which, as I learn from other publications, the great Waltham rosarian was the first to introduce into England. He was also the first cultivator of Gloire de Dijon, so greatly eulogised for colour, substance, fragrance, and durability by the Dean of Rochester in his book on the Rose. Its merits receive almost equal recognition from another high authority, Mr. Thomas Rivers in his "Rose Amateur's Guide," which I have recently been reading with exceptional interest.

The Maréchal Niel, which is perhaps with one exception—that of its grandsire—the grandest Noisette Rose in cultivation, is directly descended from the Cloth of Gold through Isabella Gray, an American production. Cloth of Gold—a superb Rose, of which in this country an absolutely perfect specimen is seldom to be seen—is the offspring of Lamarque, which I recently saw in all its integrity at Inch Manse, in Wigtonshire. The finest Maréchal Niel I have ever seen is also in the same county. It is the much-valued possession of Mr. David A. McClew, of Chapel Rorsan, in Kirkmaiden. It covers the whole side wall of his conservatory, and has often towards the end of April as many as 500 simultaneous blooms. The flowers would doubtless be considerably more imposing in dimensions than they usually are if he allowed fewer of them to grow; it is, nevertheless, at that early season of the year a very impressive picture of floral luxuriance.

Most of the leading English rosarians, such as Mr. Paul of Waltham and Mr. Cranston of Hereford, grow their Tea and Noisette Roses in large houses specially constructed for this purpose. There is, however, at least one striking exception. Mr. Benjamin R. Cant of Colchester, who won last year the fifty guinea cup of the National Rose Society, grows all his in the open air. Towards the end of the leafy month of June, when all Teas and Noisettes cultivated in glass houses are "faded and gone," he has thousands in full bloom. His greatest achievements, nevertheless, have been gained through the medium of Hybrid Perpetuals.

I see that your correspondent, "D., Deal" (page 251), makes some references to my first article in the *Journal of Horticulture* upon the "Parentage of Roses." In reply to his observations, which are characterised by courtesy, I have to say I neither affirmed that the modern Roses he specially alludes to were seedlings, nor denied that

they were sports. I was perfectly aware before writing my article that sports are variations from the leaf bud rather than the seed, and, therefore, entirely distinct from seedlings. My knowledge of the subject was sufficiently extensive to make me perfectly familiar with this fact. If one special variety is a sport from another, it is, as I can prove, quite customary for rosarians to speak in that instance of the "parent Rose," as Mr. William Paul does of The Bride, when describing it as "a pure white sport"—not a seedling be it noticed. Of Catherine Mermet am I not at least equally entitled to say that "the origin of the Duke and Duchess of Fife may be attributed to Etienne Levet and the Countess of Rosebery," or that "Marguerite Dickson is a beautiful daughter of Merveille de Lyon?" Again, your correspondent affirms I make a mistake in characterising Mrs. Paul—an impressive sport from Isaac Pereire—as a Hybrid Bourbon Rose. But Isaac himself is sometimes described as a Hybrid Perpetual; occasionally, by way of variety, I presume, as a Hybrid Bourbon. How, then, can Mrs. Paul have become, unless by some miracle, an exceptionally "pure" specimen of the Bourbon class?

Speaking of Hybrid Bourbon Roses in his "Rose Amateurs' Guide," Mr. Thomas Rivers says, "This magnificent race of Roses owes its origin to the Bourbon Rose, *itself a hybrid*; thus showing the illimitable powers of Nature when assisted by Art." I am gratified to find that your cultured contributor, while paying adequate attention to modern French Roses, does not under-estimate the value of such British productions as Marguerite Dickson, Jeannie Dickson, the Duke and Duchess of Fife, Prince Arthur, Corinna, Sappho, Her Majesty, Spenser, and Mrs. John Laing. DAVID R. WILLIAMSON.

### CULTURE OF CINERARIAS.

WHEN Cinerarias are required to flower during the autumn and winter the seeds should be sown about the end of March or the first week in April; but for spring use a sowing may be made in June or July. For seed-sowing I prefer pans to pots, as the young plants are liable to become overcrowded when grown in pots. The pans should be perfectly clean and carefully drained, placing some rough material over the drainage. They should then be filled with some fresh sifted loam and leaf soil in equal proportions, with a little sharp sand added, pressing it tolerably firm and leaving the surface smooth. Before sowing the seed some growers recommend applying boiling water through a fine-rosed can, which I believe is a very good plan to adopt. When the soil is cold the seed should be sown thinly and evenly and slightly covered, then gently sprinkled with tepid water. The pans should be covered with panes of glass and placed in a shady position in an intermediate house, where the seed will quickly germinate.

When the seedlings appear remove to the greenhouse, and when large enough to handle prick into pans and place in a cold frame on a bed of coal ashes and kept rather close for a few days to encourage root-action. When the foliage begins to touch again prick off the plants, but in the place of pans use boxes. I find they thrive much better when so treated than when put singly in small pots. As the plants progress they should be potted, using 5-inch pots for the first potting, and when the roots reach the sides of the pots transfer the plants to 6-inch or 8-inch pots. The soil for the final potting should be of a much richer nature than that previously advised. A compost of fibry loam three parts, leaf soil one part, burnt earth one part, and one part well dried cow manure, with a good sprinkling of sharp sand will form a suitable mixture for them. The soil should not be pressed too firm in the pots, for although most plants like firm potting, the Cineraria thrives best when the soil is light and friable. When the pots are full of roots liquid manure may be applied once or twice a week with advantage.

My method of cultivation differs somewhat from that usually practised respecting the positions in which the plants should be grown. Most growers recommend growing them facing north, whereas I find they succeed equally as well when grown with a southern aspect, providing a slight shading is provided them during bright sunshine. The shading should not, however, be permanent or sufficiently thick to exclude light. As the sun gets off them it is very beneficial to the plants if the lights are taken off, and a slight dewing with the syringe be afforded them, this being of great benefit as regards keeping the foliage clean and healthy, also resisting in a great measure the ravages of insects and other pests. It is also a good plan to leave the lights off all night during the summer if the weather is at all favourable, thereby letting the plants have the benefit of the dew, this being very beneficial to them.

Cinerarias are subject in all stages of growth to various insect pests, green fly being particularly troublesome, and if allowed to become established is very difficult to eradicate. A close watch should, therefore, be kept, and at the first appearance of fly the houses or frames in which the plants are growing should be fumigated. Care must be taken not to give a too strong application at one time, it being much better to fumigate in the evening and again the following morning; the foliage often presents a scorched appearance if too severely fumigated. Although these plants are subject to green fly, I think these attacks may be averted if careful and timely attention be paid to all matters pertaining to their culture. I think the appearance of fly is due to the plants receiving a check, either by not having a sufficient supply of water or allowing them to become root-bound. Soft rain water should be used where obtainable.

Soot water is an excellent stimulant for Cinerarias. The soot should

be placed in a bag and immersed in a tub of water, allowing it to soak for twenty-four hours before using. I may mention that I have adopted the foregoing treatment and have now excellent plants, some of them being 2 feet 6 inches through, with large and bold foliage. The plants are also carrying good heads of bloom, some of them being 18 inches through, the individual flowers averaging from 2 to 3 inches across, and six-eighths of an inch wide in the petals. I have only had occasion to fumigate them once all through the season.—G. PARRANT, *Ashby Lodge Gardens, near Rugby.*

### SCHIZOCODON SOLDANELLOIDES.

FEW exhibits attracted more attention at the meeting of the R.H.S. on March 28th than the beautiful little *Schizocodon soldanelloides*, shown by Captain Torrens, and for which a first-class certificate was awarded. It was brought by the exhibitor from Miganoshta, Japan, in 1891, named at Kew, and stated by the authorities there to have been the first living plant brought to England. It was first shown at the Crystal Palace in the spring of last year, and referred to in the *Journal*

FIG. 55.—SCHIZOCODON SOLDANELLOIDES.

at that period as bearing a resemblance in foliage and flowers to *Shortia galacifolia*. It is a dwarf plant, attaining to a height of 2 to 3 inches only, and bearing its charming rosy flowers very freely. A marked feature of the latter is the deep lacination of the segments which makes the flower look as if fringed. It is a most beautiful little plant, and it is to be hoped that it will seed readily, so that a stock may be procurable. We should be interested to hear whether such is the case or not. The plant has proved quite hardy during the past winter, and it may, therefore, be classed as a valuable addition to the list of choice outdoor plants. Figure 55 represents it.

### SUMMER PRUNING VINES—AN OBJECT LESSON.

HERE we have a subject which will open a wide field for discussion. I am sure readers of the *Journal of Horticulture* will thank Mr. J. C. Clarke (page 223) for his remarks on the matter. Coming as it does at the very commencement of our general Vine-growing season, it may not be out of place to describe my views respecting this question. Undoubtedly, practice combined with thought leads to success, and while, to read the laudatory lines of Mr. Clarke, the general reader might be inclined to think that having once adopted a certain line with success I was content, such is not the case, for I am daily learning.

Coming, however, directly to the main question, I do not like the word "pruning" here, as this may lead to the apparent neglect of my duties; pinching or stopping should be the correct term, it being done in very early stages with the finger and thumb or the scissors. It amounts to pruning I admit, but real pruning in the ordinary sense of the word would be an error on the practitioner's part. A Hamburgh Vine affords a good object lesson. Take the ordinary rod of from 10 to 12 feet long. What

do we find? As many laterals as there are feet each side, each lateral with at least six leaves. We stop the lateral at this length, the immediate result being an increase in size of main leaves. Then also follows a quicker growth of the sub-laterals, *i.e.*, leaves or shoots springing from the base of eyes on new wood. Now, without going into details, I may say I preserve every one of these sub-laterals, pinching immediately when ready to one leaf. My contention is that a large leaf is far more value than any amount of small foliage or elongated wild growths.

In a week or ten days the main lateral bud will start again into leaf growth. This new growth I pinch directly I can see the new shoot large enough; and so I repeat during the growing season. I find this amounts to about four growths beyond the first stopping of lateral. Many gardeners will think with me that this is top growth enough. All sub-laterals on main lateral beyond this are kept to the one leaf. In Muscats I generally remove most of these small growths below the fruit on the score of getting more light to the fruit. I treat every lateral as if fruiting. Extreme cases there may be, but I question very much if for general practice this system is to be excelled.

Leaving the top growth for the present, let us turn our thoughts to the roots. At the first stop of lateral, however active the old roots may be as sap providers, no new roots at this date are made; but this check or arrest of sap, if I may call it, at the top is the first cause of new root action. Again, I question if any other plan, *i.e.*, fine foliage would favour root growth so quick. That unchecked top growth will produce in time roots to correspond is true; but who wants roots to any extent 3 or 4 feet long? I am now dealing with the fruiting Vine. Roots of a fibrous character near the surface should be our aim, and this continuous summer pinching will favour the production of these, other conditions being favourable. Even tendrils I strictly keep down, being very sure these are a loss of strength to the Vine. I have spoken of the increase of size in foliage by this system of restriction, but omitted to note the corresponding increase of substance in texture, thick foliage being a very important feature in the well-being of the Vine growth. No amount of reasoning will ever convince me that yards of unchecked growth is ever of benefit to the Vine other than in a case of accident. Thus we may have a touch of sun-burning or scorching, or a visitation of red spider. In such instances it will be desirable to encourage a free growth.

To maintain a continuous summer and autumn growth should be our desire and aim, and heavily cropped Vines will not do this unless we feed and keep them in condition. I shall not expect the consensus of opinion to be on my side, yet even the ordinary reader must by this time suppose I should not go on year by year unless I had proof of the correctness of my practice. By accident, possibly in the busiest time, a house will get left a week beyond its usual time for stopping. Does it gain by so doing? Certainly not; it is quite the reverse, the tale being told all through the remainder of the season.

Were I to tell all I have done in way of experiments in this particular line it would fill a book. But let us revert to another point in this question of restriction. Which practice makes the best wood, and also produces the best eyes for the coming season, which after all should be a true test, even though we have to look a season in advance? I emphatically say the duly summer and autumn-pruned Vines. In conclusion I have not any possible doubt that a wild, or even a semi-restricted growth, especially late in the autumn, also produces a corresponding root growth, which probably decays or dies away during the winter unless in a very warm dry border.

It may now not be out of place if I also note that even the first year of planting I keep Vines well in hand so far as all side growths are concerned, depending on the main rod for root-action, and yet I always get good fruiting canes of good substance, and this is repeated year by year. As Vine growers we should attach more importance to the perfecting of the present year's growth, building up the eyes for something good in the next season. Owing to the lateness of new root-action, if there is not a good show we are to a certain extent powerless to increase the size feed as we will. I question very much if any feeding is beneficial until Grapes are set. In planting Peaches and Vines in March one cannot help being struck with the condition of roots, the former having many new roots, while Hamburgh Vines breaking are dormant so far as these are concerned.—STEPHEN CASTLE, F.R.H.S., *Fordingbridge*.

### SPRING FLOWERS AT HOLLOWAY.

WHETHER or not Upper Holloway gets more than its fair share of sunshine a visit on a spring morning usually finds cheerfulness reigning supreme. Possibly fogs come rolling up from the not far-distant city now and then, but they are gladly forgotten when the dark days of winter pass away. A Journal representative with a weakness for bulbs was struck by the exceptional quality of the Hyacinths and Tulips exhibited by Messrs. B. S. Williams & Son at the Royal Botanic Society's Show a few days ago, and having little time for a close inspection at Regent's Park called in at the Victoria Nurseries with a view to a more leisurely examination of the plants. He had an idea, too, in which he was not disappointed, that there would be other things worth seeing besides the bulbs.

The old order has changed with respect to bulbs during the last five or six years. Time was when almost every leading dealer had a show of Hyacinths in the spring, and a brave display they provided, but now large trade collections are few and far between. Presumably there is a

good reason for the change. Much expense attaches to the purchase of the bulbs and their cultivation, and it may be that the decreased sale price, so far at least as concerns Hyacinths, leaves too small a margin of profit to justify the outlay of a large sum on what is, after all, an advertisement of doubtful value. Many, without doubt, regret the fact, whatever its cause may be.

It is very doubtful if in the many years in which the Upper Holloway firm have grown a collection of bulbs they have ever had a finer display than that of the present season. Both Hyacinths and Tulips are magnificently grown, and many bulb lovers must have noted with pleasure the splendid trusses of the former, and the large, substantial, shapely blooms of the latter. Such Hyacinths as Lord Derby, King of the Blues, Koh-i-Noor, Von Schiller, Charles Dickens, La Française, King of the Blacks, Captain Boyton, and La Grandesse may be instanced as splendid examples, the trusses being large and massive, and the foliage of the dwarf character which adds so greatly to the quality of the plants, but many others might also be mentioned. White Joost Van Vondel, Proserpine, Vermilion Brilliant, Chrysolora, Ophir d'Or, Murillo, and Van der Neer were a few of the most noteworthy Tulips. The wisdom of the Dutch growers in meeting the increasing demand for these splendid flowers by enhancing the prices considerably was questioned in these pages some time ago, and not without reason.

Clivias constitute a useful class of plants for winter and spring flowering, a trifle too robust perhaps in colour to suit some tastes, but none the less acceptable during gloomy weather. We do not see them so widely employed as window plants as might be expected. It is a use to which they are admirably suited. Messrs. Williams & Son grow them somewhat largely, and their plants are now in fine bloom. Aurantiacum; the rich reddish orange Meteor, one of the largest and brightest of all; Model, and Ambrose Verschaffelt with its huge truss, may be noted as four of the most conspicuous.

The Amaryllis have wintered well, and are showing some very fine spikes, a large proportion having two to a plant. The house in which they are grown has a middle bed the length of the structure, with side beds also. The plants are plunged in ashes, which is preferred to fibre; but in the winter, whilst in the resting stage, they are lifted out of the ashes, and stood on the top; then in the middle of January, when repotting takes place, plunging in ashes up to the rims of the pots is the course of procedure adopted. Little water is applied until strong growth commences, the watering process being increased as growth advances; this goes on until they have completed their growth, then the water is gradually withheld until they become quite dry. A few of the best sorts were the following:—Ophelia may be regarded as one of the very finest in the collection; it is a light-coloured flower suffused and shaded with purple, having a narrow crimson margin, flower 7½ inches in diameter, and of good substance. Harry Williams is one of the very earliest to flower, a bold bloom of a deep crimson colour speckled with white. George Wainwright is a large flower, being 8 inches in diameter, of fine substance and good form. Dazzle is a fine bright scarlet, having a central white stripe. Loveliness is extra fine, very soft salmon in colour. Joseph Broome, deep purplish crimson, is a well shaped flower. Distinction is a large orange-scarlet, base of segments light green. Emperor Frederick is 8 inches in diameter, deep orange scarlet and purplish crimson, very fine. Crimson Banner is a very strong grower, crimson, with a stripe of white down the centre of each segment. Maiden's Blush is a charming variety of fine form and substance, white ground suffused and striped with crimson; one of the best. Lord Salisbury is a fine bold flower, colour crimson purple. Princess Victoria, pure white, is very fine in shape and substance; as a rule it has two spikes with five flowers on each.

The Orchid department contributes a distinct quota of interest. The Vandas, for which the Upper Holloway nursery is so famous, are in splendid health and bearing many flowers. *V. suavis*, *V. tricolor insignis*, and *V. tricolor superba* are all beautiful. Cymbidiums have sent up wonderful spikes of buds, and in a few weeks will be a beautiful sight, and a magnificent piece of *Cattleya Lawrenceana* is full of sheaths. *Laelias* are flowering brightly, *L. harpophylla* and *L. flava* being conspicuous amongst them; so too are *Calanthes*, *Lycastes*, such as *costata* and varieties of *Skinneri*, and *Cattleya Trianae formosa*, a richly coloured form. *Dendrobium Findleyanum* is bearing dense clusters of flowers, and there is another striking representative of the genus in *D. infundibulum giganteum*, a large and beautiful form. *Cypripediums* contribute largely. In the cool houses *Odontoglossum crispum* is represented by many beautiful varieties, the whites being charming to a degree. *O. prionopetalum*, *O. mulus Holfordianum*, and *O. cirrhosum* are also in bloom. The two first-named have much the same colouring, being lemon with brown blotches, but they differ greatly in other respects.

Foliage plants are abundant and healthy. Crotons and *Dracenas* are a special feature. *Aralias*, such as *Veitchi* and *Reginae*, are also in strong force. These add interest to a visit, and all who have an hour or two to spare will spend it wisely if a call at Williams's is decided upon.

### BROCCOLI.

IN the cultivation of this esteemed winter and spring vegetable various circumstances have much to do with the results obtained. It would be utterly useless to attempt to grow Broccoli, even fairly well, on such land as I have to deal with, if it were not dug prior to planting. Plants put out in undug land do not make nearly enough growth to

ensure a crop of even fair sized heads. When strong land has to be dealt with effectively, it must not be allowed to lie long enough to become solid before planting.

Every cultivator has to study the peculiarity of his own soil, and deal with it accordingly. My opinion is that sowing the seed is too long deferred. The plants have not then sufficient time allowed them to grow large enough to give the best results. It is not a question of obtaining extremely large leaves and gross stems by heavy manuring and liquid stimulants, but it is rather the plan of allowing sufficient time for the plants not only to grow to a full size, but to mature before severe frost sets in. In this latter detail lies the chief secret of successful Broccoli cultivation.

Manure is essential, but not to the extent that many persons imagine it is. The land must be made rich enough to produce leaves and stems, but not so gross as to prevent maturation taking place afterwards. We commenced to put our plants out last year on June 1st, being assured then of a long season of steady growth. A second breadth, planted three weeks later, exhibits a marked difference at the present time. The same piece of land has been occupied continuously for the last twelve years with Broccoli and Brussels Sprouts alternately. The land receives an occasional heavy dressing of quicklime. No manure is used that year. We always dig the land during dry weather; the drier it is the better we like it. The year following the liming process as much manure is used as can be covered, but, as very often happens, this is little better than straw and we do not scruple at the quantity. We plant in dry weather, and water the plants once or twice, and have then little trouble from slugs. We never earth-up the plants when growing, nor lay their heads to the north upon the approach of winter.

The following notes will show the varieties and the results after the experience of the winter. Winter Mammoth, planted on the 1st of June, was ready for use six weeks before the appointed time, owing no doubt to the peculiarity of the weather. Leamington has come out of the ordeal remarkably well, out of 750 plants there were only sixty dead from the effects of the frost. Our stock of Late Queen numbers 800, not more than thirty have succumbed to the effects of winter. For trial I put out this year 100 plants of Sutton's Pearl, and only sixteen are dead, so this appears to be a deserving variety for further trial. Vanguard, grown for the first time, suffered considerably by the frost. I omitted to say that we put out the plants direct from the seed bed. I cannot see the advantage of transplanting them previously, but we endeavour to get them into their permanent position before they are at all weakened by overcrowding.—E. M.

### CULTURE OF PLUMS IN POTS.

IN continuation of my remarks on Plums in pots on page 215, I may say that it is better to purchase trees already formed and established in pots than to rear them. If furnished with blossom buds, and given proper treatment, they will bear a crop of excellent fruit the first season. Trees two or three years from the bud or graft are suitable for potting from the open ground, if they have been transplanted the year previously; they will be more or less provided with blossom buds, and, being potted as soon as the leaves fall, a crop of fruit may be had the following year, but the fruit will not be as large and well flavoured as that produced by trees established a year or more in pots.

The pots used must be proportionate in diameter to the size of the trees, 10-inch to 12-inch pots accommodating those of the age mentioned. A suitable compost is three parts rather strong calcareous loam and one part decomposed manure, a 9-inch potful of bonemeal and a quart of soot being added to every 3 bushels of compost. Calcareous loams generally contain enough silicious matter—stones or flints; but strong loams are often deficient both of grit and lime. In that case add a fourth part of sifted old mortar rubbish to the compost; if the loam is fibrous use Thomas' phosphate instead of bone dust. In all cases it is necessary to provide good drainage, potting firmly, and allowing sufficient room in the pots above the soil for the large quantity of water required in summer. This is a great point in Plum culture in pots, for they not only require abundant liquid feeding, but space for surface dressings, so as to get as many feeders as possible. The trees may be placed outdoors in a sheltered situation after potting, and on a bed of rough ashes, surrounding the pots and up to their rims with finer ashes. After a year's growth outdoors they may be placed under glass, but some prefer to pot maiden trees and grow them under glass. I prefer placing the trees outdoors every year after the leaves fall, but all the great authorities on orchard house trees, except Mr. Douglas and the Rev. W. Wilks, prefer to keep them under glass.

The trees in spring—before the buds are so far expanded as to show colour—must be stood apart or be returned to the house, allowing each plenty of room for the development of its growths, and standing each pot on two or more bricks on the flat, a little distance apart, so that the roots will not pass into the soil, whilst insuring a free passage for the drainage water. Such trees are perfectly under control, and they can be moved anywhere at any time without prejudice to the growth.

Success or failure with Plum trees in pots depends greatly on the attention given to watering. They must never be distressed for lack of a supply. In summer they require water twice, sometimes three times a day; also surface dressings of rich compost, pieces of turf preferably, to encourage plenty of surface roots, which can be fed to any extent by liquid manure and sprinklings of artificials occasionally. This is absolutely essential to sustain the trees in health and fertility.

From the time the fruit is set until it begins to ripen each tree should be syringed early in the morning and in the afternoon, except on dull, cold days. Red spider is kept under by those means, and other insects must be subdued by the prompt use of insecticides. When the fruit is gathered the trees, especially the early varieties, may be placed in a sunny position outside, and receive proper attention to watering and syringing, or they may be kept under glass constantly, but there is not the least necessity for it, and glass is worth much in winter for plants that really do require such protection.

If the trees are kept under glass the ventilators should be wide open whenever the temperature is above the freezing point; when frost prevails they should remain closed. In those circumstances the trees will naturally start sooner in spring than those that have been placed outside, and from this time forward a circulation of air, except in severe weather, should always be maintained by leaving the ventilators open more or less day and night. Plenty of air and a dry atmosphere is the way to secure a proper set of fruit. By the time the fruits are set and swelling the sun will have considerable power, and may be taken advantage of to accelerate the growth by reducing the ventilation in the afternoon, yet leaving some on, airing early each fine morning, and when the wind is cold and sharp ventilate on the opposite side to that on which the wind blows. In summer the ventilators should be left open day and night, but some wire netting must be tacked over the ventilators so as to exclude birds.

The fruit must be kept dry when it is ripening and as long as it remains on the trees afterwards. Wasps and bluebottle flies like ripe Plums. Hexagon netting over the ventilators and frame doors covered with it exclude them, otherwise use the thinnest muslin over the trees or enclose the fruits in bags of that material. After the fruit is removed recourse must be had to syringing, watering, and proper supplies of nourishment for the perfecting of the wood and buds for next year's crop. Repotting or top-dressing should be done before the leaves fall.

As to the training of the trees, bush and pyramid forms are best, a tree of the latter being easily formed by pinching the side shoots, and topping the leader to secure them. Summer pinching may be practised twice or even thrice on the leader, and the side shoots once or twice to four or six leaves, the growths on these and branches being stopped at three leaves, taking care to avoid overcrowding, otherwise the fruits are deteriorated for lack of light and air. Pruning may be performed early in spring, and will mainly need to be confined to thinning, and removing exhausted and superfluous shoots.

Plum trees in pots are fine for table decoration when laden with showy luscious fruits. Those with red fruit tell best, a pyramid about three years old in a 9 or 10-inch pot, and carrying five dozen of fruits, are singularly effective, one of the best being Czar, its bluish hue rendering the fruit very attractive. Yellow Plums are very beautiful.—G. ABBEY.

### CARNATION NOTES.

#### BORDER VARIETIES.

THE three varieties recommended below are worth growing extensively; in fact, they look best when whole beds are planted with them. Marquis of Lorne is a good dark flower that seldom splits its calyx, and the same may be said of the other two. This variety is the tallest of the three, and is a very good grower. Queen of Bedders may be described as a good red Carnation, and of dwarf sturdy growth, very free, large flower; the flower stems seldom exceed 18 inches in height. This variety forms a charming bed, and should be grown in quantity to display its beauty. Hotspur is a grand companion to the above, being pink in colour and practically of the same habit of growth. These two kinds were selected from amongst many others at Messrs. Turner's nurseries, Slough, and they have fully borne out the high opinion we then formed of them. For cold, late, and rather damp localities these three kinds may be relied upon to do well.

#### GOOD CARNATIONS FOR POT CULTURE.

Mrs. Reynolds Hole and Miss Mary Morris are excellent varieties for growing under glass. The former, although it possesses no scent, is a most popular variety amongst ladies, its salmon apricot colour being very striking. It does well in pots, and will if occasion requires bear gentle forcing. When grown under glass the plants naturally flower before those outside; the flowers produced under glass are even more delicate and striking in colour.

Miss Mary Morris when grown under glass is so delicate in colour that one can scarcely recognise it. The flower is large, and being so delicate it forms a good companion to the more striking Mrs. Reynolds Hole. To grow these varieties well in pots strong healthy layers should be selected from plants that have been layered outside. They can be placed singly into 4-inch pots, or three may be put into 5-inch pots. These should occupy cold frames until the end of the year, and then be placed in the greenhouse. When well rooted they can be placed into 6 and 8-inch pots respectively. This course should be followed when the plants are to be brought forward into bloom as early as possible; but when they are to flower under almost natural conditions they ought to be kept in frames, or even stood outside on beds of ashes, and only removed under glass to flower.

The old Crimson Glove is much more beautiful when grown in pots under glass than when flowered outside. This variety, on account of

its fragrance, is highly appreciated, and well deserves culture under glass. The plants need the same treatment that has been advised above.

#### SOUVENIR DE LA MALMAISON CARNATIONS.

The healthiest specimens and best blooms are produced when the plants are grown perfectly cool throughout. Plants that have flowered with one spike in 6-inch pots under cool treatment make from three to six strong growths, and flower the second season. The plants after flowering should be stood outside on beds of ashes, and carefully watered. At this season these plants may be placed into 8 or 9-inch pots, according to their size and the number of roots they possess. After potting these plants will do much better plunged in frames than in an ordinary greenhouse. The growths should be carefully staked to prevent them breaking. When well grown Lady Middleton produces a very large flower, and is even more highly appreciated than the ordinary form, although it is indispensable where these Carnations are appreciated. The scarlet form (Madame Arthur Warocqué) flowers freely, and is a great acquisition, but is of rather weak growth compared with the other varieties of Malmaison, and appears to be very shy of producing grass for stock.

These plants do well in two parts good fibry loam, the other part being composed of leaf mould and coarse sand; to this one-seventh of decayed manure should be added, but this should be passed through a fine sieve.—O. M.

#### HARDY FRUIT GARDEN.

**Grafting Apples and Pears.**—Grafting may still be proceeded with, especially with late varieties and in cold backward districts. In some parts of the country it can be performed successfully as late as April 25th, but as a rule the early part of the month must be considered the best period in midland districts, March answering better for southern localities. Much, however, depends on the season, which in a great measure accelerates or retards the activity of the sap. Free sap movement in the stocks to be worked is the first essential to success, that in the scions being comparatively quiescent at the time of insertion. The latter being procured and stored in a moist cool spot some time previously will be in the right condition.

**Preparing Stocks and Scions.**—Stocks of considerable diameter which it is intended to work, having been prepared by heading down some time ago, will only now need the removal of a thin layer of the upper surface in order to present clean fresh wood and bark to the operator. The scions should be healthy portions of the previous year's wood about 6 inches long, containing at least four bold wood buds. The central parts of shoots are regarded as the most suitable. The immature tips can thus be discarded as well as the basal portions of shoots, which do not generally contain wood buds of the right character. In preparing the scions for insertion, after cutting them to the proper length, cut the lower half in a sloping direction, beginning in front of the lowest bud and, making a clean cut downwards, taper off to a wedge-shaped point. Form a notch or small shoulder at the top of the slanting cut, so that when inserted in the stock each scion will rest firmly in position.

**Form of Grafting.**—There are various modes of grafting employed. The method for young stocks, where stock and scion are of equal thickness, is that known as whip grafting. The details in the preceding paragraph refer to crown or rind grafting, which is the method usually employed when grafts are inserted on old trees, as several scions can be introduced on one branch or stock.

**Inserting the Scions.**—For crown grafting, as each scion is prepared lose no time in slitting the bark of the stock to the required length and lift the bark, which will easily separate from the alburnum, with a piece of wedge-shaped ivory, or other smooth, hard substance. As this is done slide in the scion until the notch or shoulder rests upon the face of the stock. Take care that the inner barks unite perfectly, without which a union cannot take place.

**Securing the Grafts.**—Promptly tie with matting, and cover with grafting wax. A mixture of two parts clay to one of cow or horse manure answers well, but wax is the best. Clay and manure mixtures are liable to crack and fall away, to avoid which moss is sometimes tied over and kept moist.

**Pruning Outdoor Figs.**—Trees against walls which have received protection, and have had it gradually removed, may now be pruned. Shorten back to one eye the shoots which bore fruit last year, and which were partially shortened in the autumn. Reserve last season's shoots full length, for towards the extremities of these the crop of fruit for the forthcoming season will be found. Remove crowded wood entirely. In some positions pruning may be practically dispensed with, as when the trees make little else but short-jointed fruitful wood they are better left alone.

**Treatment of Newly Planted Fruit Trees.**—See that all recently planted fruit trees are securely staked to prevent swaying. In dry weather on light soils watering may be necessary. After one

good application of it apply a mulching of short manure over the roots. In cold wet weather and on heavy soil the trees will be better without any mulching until hotter weather sets in, the object being to allow the sun and air to warm and aerate the surface, which during this period should be kept open and loose with the hoe.

**Applying Sewage.**—Where valuable liquid drainings of all kinds are carefully preserved for use in the garden the present is a fitting time to empty the tanks or receptacles containing such. Large old fruit trees and bushes—Currants, Gooseberries, and Raspberries—are improved by its use if discretion is exercised in applying it. It is not well to use it too strong. Better give a second application than one strong dose only. Dilute with 4 to 6 gallons of water. Urine diluted with six times its quantity of water or soapsuds is a useful stimulant. The drainings from manure heaps and stables ought to be utilised. Strawberry plants revel in good support applied to the roots just when new fibres are becoming active and claiming nutriment.

**Applying Artificial Manures.**—The present is a good time also to apply artificial or chemical manures to trees and bushes that need assistance. For Strawberries on light soils a nitrogenous manure is helpful. One of the best is nitrate of soda applied in a finely divided state, mixing it with fine dry soil for equal distribution at the rate of 1 oz. to the square yard. This manure alone or mixed with double the quantity of superphosphate of lime will give increased vigour to Strawberries. It should not be allowed to touch the young foliage, but be carefully spread among the plants. Superphosphate may be applied to fruit trees at the rate of 4 ozs. to the square yard, spreading it on the soil around the stems as far outwards as the roots extend, which will be equal to the extent of the branches. Sulphate of ammonia has a similar though not such a rapid effect as nitrate of soda. Use it at the same rate—namely, 1 oz. to the square yard, but it is better mixed with double its own bulk of mineral phosphate and half the quantity of potash, this forming a suitable mixture which may be given to Strawberries growing in heavy cold soils or fruit trees generally in similar soil. The advertised artificial manures also produce excellent results when used in accordance with the directions.

#### FRUIT FORCING.

**Peaches and Nectarines.**—*Earliest House.*—When the stoning is completed and fruit desired ripe as soon as possible, the temperature may be maintained at 70° to 75° by artificial means, falling 5° through the night, keeping through the day from sun heat at 80° to 85°, with top ventilation at 75° and front at 80°, so as to insure a circulation of air. Close the house at 80°, and sufficiently early to allow of an advance to 85° or 90°, the trees being well syringed and a good atmospheric moisture secured, which will insure the fruit swelling to a large size. The foliage and fruit must, however, become fairly dry before night, and clear rain water be used, as spring water sometimes contains mineral matter, leaving a deposit on the fruit, which is a great blemish. Remove the leaves over or in front of the fruit, and turn it up to the light by thin laths placed across the trellis, as it greatly adds to the appearance of the fruit when it is well and evenly coloured from the apex, and secures the highest flavour. Cease syringing the trees when the fruit commences ripening, but maintain a genial condition of the atmosphere for the benefit of the foliage by damping available surfaces twice a day. Only the earliest varieties, as Alexander, Waterloo, and Early Louise Peaches, with Advance Nectarine, will be in the condition described, and they are best grown in a house or compartment by themselves.

Midseason Peaches and Nectarines, as Royal George and Stirling Castle Peaches, with Lord Napier Nectarine, must not be subjected to higher temperature than 60° to 65° at night, 70° to 75° by day with gleams of sun, and 5° to 10° more on bright days until the stoning is completed. These trees must be well syringed and every part kept perfectly free from red spider by washing them twice a day with clear soft water through a syringe. Supply weak tepid liquid manure to the roots if needed, otherwise keep well watered, aided by light mulching, for deficiency of moisture at the roots causes the fruit to ripen prematurely and have little or no flavour. Stop or remove all gross shoots before they have drawn the supplies of sap from the weakest parts of the trees. Leading shoots may be allowed to extend over uncovered parts of the trellis, pinching the laterals to one leaf as produced, and taking out the points of shoots intended for next year's bearing at 12 to 15 inches if likely to interfere with other growths or much exceed that length. Turn any leaves aside that shade the fruit or otherwise interfere with the colouring process.

**Houses Started at the New Year.**—Where disbudding and heeling-in the shoots have been attended to the trees will not be encumbered with more growths than are necessary for the perfection of the current crop and providing for the succeeding, every growth being allowed full exposure to light, as it is a mistake to permit more growths to remain than are necessary for next year's crop or for the extension of the trees. Allow plenty of room in the ties, not tying closely down for some time longer. Stop or remove gross growths, equalising the vigour through the branches of each tree by distributing the shoots regularly. Shoots pinched at three or four joints of growth to serve the double purpose of attracting the sap to the fruit and prevent its being drawn away should only be allowed moderate extension, stopping each sub-lateral to one leaf. Enough shoots should be permitted as will shade and protect the strong wood from the direct rays of the sun as the season advances. Ventilate freely but carefully, avoiding cold currents of air and sudden depressions of temperature. Thin the fruits if still too thick, or those left on the trees will not only attain a larger size, but with the trees in good health it is more likely to stone well than when they are over-burdened. Inside borders must be watered as required;

excessive watering and feeding induces growth at the expense of the fruit stoning, therefore be guided by the condition of the trees and crops.

**Houses Started in February.**—Trees that were set to work early in that month will have been disbudded, and the growths retained heeled-in. Those started later in the month should be examined frequently for disbudding, commencing with the forwardest and strongest parts of the trees, being careful to preserve a shoot at the base of the current year's bearing branches, and to leave no more shoots on the extensions than will be required for furnishing the trees with bearing shoots at 15 to 18 inches distance apart along the main and subsidiary branches, and all the others on extensions may be pinched to form spurs. A shoot on a level with or above the fruit must be retained on each bearing shoot, and be pinched at the third joint. As the fruit swells freely remove those worst placed, and leave only a few more than will be required for the crop. Syringe on fine mornings and in the afternoon. Commence ventilating early, increase it with the sun heat, and close so as to secure a slight rise of temperature.

**Houses Started in March.**—The trees that were started early in last month are out of bloom, and should be syringed occasionally to assist the fruits to cast off the remains of the flowers; and on fine days they may be moderately syringed in the morning and afternoon, but excessive washings are not desirable, as they only induce growth and weakness. Secure sturdy growth by free ventilation on all favourable occasions. Proceed with disbudding gradually, a little and often, and observe the same in thinning the fruit, rubbing off those that are small and badly placed as soon as the most promising can be selected. If there is any trace of aphides promptly apply an insecticide, or fumigate the house on two or three consecutive evenings moderately, taking care to have the foliage dry, deliver the smoke cool, and not give an overdose.

**Late Houses.**—All that is necessary is to prevent injury to the blossom from frost or damp. When the days are bright free ventilation will be all that is needed, with sufficient warmth in the pipes at night to exclude frost, but when the days are raw, dull, and wet it is desirable to turn the heat on in the morning so as to raise the temperature to 50°, and keep it at that with a free circulation of air, turning off the heat early in the afternoon so as to allow the pipes to cool before night and the temperature falling to its right minimum of 40° to 45°, which is quite safe, and ought to be secured after the blossoms expand, with a little air to prevent the deposition of moisture on the flowers through the night. The trees should be shaken to assist fertilisation, and artificial impregnation may be resorted to by dusting the flowers with Pampas plume, a rabbit's tail mounted on a stick, or camel's hair brush.

**Figs.**—**Earliest Forced Trees in Pots.**—The very early varieties, St. John, Early Violet, and Angelique require free ventilation and full exposure to the sun, the fruit being now ripe or ripening. These varieties are useful for supplying early fruit, but they have not the quality of White Marseilles and Brown Turkey, which, now showing signs of ripening, should have the ventilation increased and be exposed to the sun as much as possible. All cannot have this, but judicious stopping, thinning, and tying the growths will help them. The temperature should be 60° to 65° at night with a little air, 70° to 75° by day artificially, and 80° to 85° with sun. Top ventilation should be given at 70°, increased at 80°, and a good moisture maintained whilst the fruit is swelling, but syringing the trees must cease when ripening commences, and a circulation of warm rather dry air secured constantly, for fruits ripened in a close moist house are insipid. Where syringing has been practised red spider makes little progress, but when atmospheric moisture is reduced it spreads rapidly, therefore no effort should be spared to keep the foliage quite clean up to the ripening time. Supplies of water are needed at the roots at all stages, and the trees may be syringed at times during the ripening season by gathering all the fruit ripe at one time. For private use Figs should be thoroughly ripe when gathered, but for marketing purposes or packing they may be gathered before they are fully ripe. Brown scale also increases rapidly over the young shoots and extends to the leaves and fruit. It must be kept under by the timely use of an insecticide, carefully applying it with a brush or sponge upon the first appearance of the pest. Red spider may be treated similarly, the thing is to contest insect invasions before they become firmly seated on the plants.

**Succession Houses.**—Trees permanently planted out in borders require water and liquid nourishment in proportion to the vigour of the trees, their crops, and the rooting area. With the roots restricted to a narrow border large quantities of water or liquid manure will be required; those having the run of a large border will need less, but large trees and borders are great mistakes in Fig culture. Syringe the trees twice a day when fine. Let the night temperature range from 55° to 60°, 70° to 75° by day with gleams of sun, and 80° from sun heat, ventilating from 70° and fully at 75°, but with an advancing temperature to 80° or 85°, closing at 80°, and sufficiently early to cause the temperature to rise 5° or 10°. Keep the growths regulated, thinned, and stopped, avoiding overcrowding as the greatest evil in Fig culture.

**Late Houses.**—Trees in these and wall cases must now be tied in and syringed on fine days, but sufficiently early to allow the trees becoming dry before night. Fire heat need only be employed to exclude frost where the fruit is required late. Trees in unheated houses should be retarded as much as possible by free ventilation in the daytime and in mild weather, and the house kept dry at night, syringing not being practised over the trees in the early stages of their growth. Cold houses, however, are not the best to insure success, though the trees afford one crop annually as a rule, yet in cold localities there should be some provision for keeping out frost in the spring and ripening the wood in

the autumn. In winter the trees are quite safe tied in bundles and protected with dry straw or bracken, with dryness at and a mulch over the roots.

#### THE FLOWER GARDEN.

**Carnations and Picotees.**—Once more young plants have proved much the hardiest. Stems of old plants not being protected by leaves are most susceptible of injury, and not a few beds of them are scarcely worth preserving. If there are any young plants in pots under glass, and intended for the open borders, these should be hardened off and planted out before they commence to produce their flower stems. They will be useful for filling up gaps, or may be planted in slightly raised beds, 6 feet or rather less in width, planting them about 1 foot apart each way. If they cannot have the benefit of quite fresh loamy compost, they ought at least to be surrounded with a mixture of fresh loam, old Mushroom bed manure, or better still, horse droppings swept up from the roads and grit of some kind. The soil should be well rammed about the balls of old soil and roots with the handle of the trowel. Lightly hoe among established plants, and mulch with leaf soil or old Mushroom bed manure.

**Carnations and Picotees from Seed.**—The Marguerite Carnations will flower strongly the same season they are raised, providing the seed is sown moderately early. In order to be certain of their flowering in August or September, the seed ought to be sown in gentle heat in March, but if seeds are at once sown the plants would yet flower if protected or lifted and placed under glass. The seed germinates in about a week or nine days, and as surely as Aster seed. When well into rough leaf prick the seedlings out 3 inches apart each way in boxes or pans of good loamy soil, or else place them singly into 3-inch pots. Keep them in gentle heat till they are rooting afresh, after which cold frames or pits are the best positions for them till they are strong enough for planting in the open. Seedlings of the ordinary border Carnations and Picotees flower grandly during the following season, but are rarely of much service afterwards. The stock must, therefore, be kept up by means of layering and raising of seedlings every spring. Sow the seed thinly in either pans or boxes of fine soil previously well moistened, and place in very gentle heat—a newly started vinery answering well—to germinate. Much fire heat is objectionable, a cold frame being preferable to strong heat for raising seedling Carnations.

**Half-hardy Annuals.**—If seed of Asters, Stocks, Zinnias, Dianthus, Phlox Drummondii, Godetias, miniature Sunflowers, Perilla, and such like are sown now the plants will be in excellent condition for the open beds or borders late in May or early in June. Sow rather thinly in boxes or pans, and place in gentle heat. If squares of glass are available cover with these, shade heavily from bright sunshine, and see that the soil never becomes dust dry. When the seedlings are well up gradually expose to the light. Soon after the first rough leaves have formed prick the seedlings either in other boxes and pans, or on shallow beds in frames and pits. Given the benefit of good loamy soil, and a little warmth and shade, all will soon start growing strongly. Variegated Maize (*Zea japonica*) and Ricinuses may also be sown now.

**Hardy Annuals.**—There are a considerable number of beautiful kinds and varieties that may be raised in the open borders where they are to flower. These comprise Alyssum, Bartonias, Calandrinia, Calendula, Candytuft, Cornflower, Chrysanthemums, Coreopsis, Eschscholtzia, Gilia, Godetia, Gypsophila, Hawkweed, Helichrysum, Hibiscus, Larkspur, Leptosiphon, Limnanthes, Linaria, Linum, Love-Lies-Bleeding, Lupine, Malope, Mignonette, Nemophila, Oenothera, Sanvitalia, Saponaria, Silene, Sweet Sultan, Sweet Peas, Tropæolum, Venus' Looking-Glass, Viscaria, and Xeranthemum. Supposing the ground has been laid up roughly during the winter or for the past month, a showery time during the early part of April should be taken advantage of for fining this down and sowing the seed. The usual practice is to sow all in circular patches a foot or rather less across, and it is a good plan to form these slightly below the surface, covering with a little rich finely sifted soil. Avoid crowding of either the patches or seed, annuals to be seen at their best requiring good room. A close look-out must be kept for slugs, trapping these either with Broccoli leaves, or better still heaps of bran or brewer's grains.

**Ornamental Grasses.**—These may be treated exactly as advised in the case of other hardy and half-hardy annuals, but merit a separate reference. If required principally for drying, and they are very serviceable in that state during the winter, they ought really to be grown in a kitchen garden border where there will be nothing to prevent cutting the flower heads directly they are fit. They vary greatly in height, but if sown thinly in lines 12 inches apart across a border, no mistake will be made.

**Poppies.**—Those that are annuals are among the gayest of summer flowering plants, and there are many beautiful single and double flowering varieties, the Japanese section of the latter being not unlike good Japanese Chrysanthemums, but their beauty generally is of a fleeting character. If sown in patches in mixed borders they are not so much missed in the late summer and early autumn, but they are very gorgeous in masses. No time should be lost in sowing the seed, not forgetting a good breadth of the charming Shirley Poppies. Avoid sowing thickly, and thin out the seedlings freely.

# THE BEE-KEEPER.

## APIARIAN NOTES.

### CYPRIAN BEES.

AT Craighet there is a hive of Cyprian bees apparently pure, that "A Renfrewshire Bee-keeper" imported about six years ago. Within several miles of Craighet there is an extensive bee-keeper who manages his bees on the two queens in one hive system and the joining of swarms—swarming them artificially, a proof in itself if there were no other, that the two queens in one hive plan is not a new idea. It is now some ten years since this gentleman took the bees in hand, I believe encouraged by the late "Renfrewshire Bee-keeper," from whom, no doubt, the profitable methods of management were conveyed, and so pleased is he with the results that he is on the eve of extending his apiary. By his good management he scores a large profit, and attends to his business regularly in Greenock.

The farmers in the neighbourhood complain that they have no honey as the bees above alluded to take all there is. This is certainly not the case, as there are only hundreds of hives where thousands might be profitably kept. The cause of the farmers' failure is due to keeping too small hives and the bad seasons combined. Instead of grumbling at the failure of the honey yield, they should adopt the system so successfully carried out by their supposed rival, and do as he does, keep stronger hives, and manage them properly.

### MR. BENTON AND PUNIC BEES.

Bee-keeping is like many other rural pursuits, most profitable in the hands of experts. I do not mean certificated ones, but men or women who can trace cause and effect, working out their own programme and ideas, and leaving the teachings of the facile writer but inexperienced bee-keeper outside his daily care. Nor is that all. Bee-journalism and dealerism, with petty jealousy and ill-feeling, have done much to hinder real progress. The editor of one American bee paper charges Mr. A. J. Root, the editor of "Gleanings," as being unfair in suppressing one side of the question on Punic bees, which Mr. Root denies, and then puts a stop to the controversy, quoting Benton, Baldensperger, and Cowan in support of his views. The first named gentleman, when making money by the sale of these and other foreign bees, praised them highly. They had no bad qualities in his opinion then. In a letter to me before quitting Austria he gave the Tunisian bees a very high character, particularly that of making extra white comb. I answered him, but neither obtained bees nor reply. It is not that that troubles me; but the reason that his statements are irreconcilable. At the Washington Convention he stated "That the temper of the Punics was ten times as bad as that of the Cyprians." I never found the Cyprians very spiteful, and the Punics seem even milder in temper; but they must be approached in a sensible way. The other persons named have not, in my opinion, had sufficient practical experience with these bees. I append a letter from Ireland:—

### HIVES AND FEEDING.

I herein note down a few observations I have made during the past two weeks. My bees have worked well since the 14th of March. On Monday the 20th we had an ideal day for bees, and it was very pleasant indeed to hear the bees and to see how busy they were. The thermometer was standing at 60°, the warmest we have had this year. I was very anxious to know how they all stood for stores. I examined all my ten hives, eight of which are Blantyre's, and found all, as near as I can estimate, fully 20 lbs. of sealed stores. Every hive is, in my opinion, a model of what a hive should be at this date. I have never extracted any honey from the brood combs of my hives; in fact, I have not procured an extractor yet. As I want the greatest possible amount of well-finished sections I have not given any sugar to any of my stocks since September, as all my observations have taught me that to use it profitably it should be given while the bees can seal it thoroughly before the wintry nights come on us.

I had a little experience with spring feeding two years ago. Although I used every precaution, and fed two hives that were neglected to be fed in time in the autumn, I failed to get them ready as soon as the bees that had not tasted a drop of syrup all through the spring. I had to feed all my bees in May two years ago. Through your advice in the *Journal of Horticulture* that was done profitably, for when the weather took up fine in June I had a good return in honey, which I attributed to keeping my queens laying, and preventing the destruction of brood and eggs. This is the first winter I have seen my bees pass through without seeing a speck of voided excrement on any of my hives. The winter came on so early, and the Ivy was so late in coming into flower that my bees never had a taste of it; other years I have seen them gather a good deal of both honey and pollen from it when we get the Ivy fully open about the last week of October and first week

of November, with a few fine days and frosty nights. Bees require a little management, as I find if I do not have all thoroughly porous on top and regulate the entrance the hives become completely logged with wet. If this is not at once remedied such a hive is at once on the down grade. The ventilating floor that you so strongly recommend is to me indispensable, and no hive can be perfect without it.

### PUNICS IN IRELAND.

I was induced through all that was written for and against Punics to give them a trial, and obtained one pure mated queen and four virgins; but one of the latter was lost in mating. I have also one Carniolan from Messrs. Neighbour. They look to me somewhat like the Ligurians I had and discarded. They are behind all the Punics as workers. Three of the Punics are extraordinary hives. To see how these bees work is simply a pleasure that none but those who have never seen could enjoy. The pure stock, I think, is leading by a little. I have on three occasions since the 20th ult. noticed these bees at the entrance fanning in air as late 8 P.M., with the thermometer at 45°. Although a strong heavy hum in all the others, none of them had a single bee within sight at the entrance now (1½ inch wide). If these Punics do not develop some bad feature during the coming season I will have none other.—PETER BLOCK.

The foregoing notes impart nothing but truth. The writer has the good of his neighbours as well as his own at heart, and having experience with different varieties of bees in this country his evidence is consequently of more substantial value.—A LANARKSHIRE BEE-KEEPER.

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Cutting Down Holly Hedge (E. C.).**—The hedge may be cut down now, and when fresh buds commence pushing saturating the ground with clear water, then following with liquid manure, would greatly tend to promote free healthy growth.

**Planting Gladioli (S. York).**—Certainly Gladioli may be grown as "far north" as where you reside, and are, in fact, splendidly grown a great deal further north—in Scotland. They are grown as well in the north as the south, if not better. The time for planting should be governed by the weather and the consideration of the soil, not by the almanack. We have planted in February in light soil in a free dry state, and in April in strong land with equal satisfaction. Any time from the middle of March to the middle of April is suitable, always taking advantage of favourable weather when the land is dry on the surface.

**Rhubarb from Seed (M. C.).**—Plants can be raised from seed quite easily by sowing in the open ground during fine weather in April. It is a good plan to sow in drills a foot apart, placing a few seeds at intervals of a foot, then when the plants appear thin them out as may be needed, allowing one to remain. These plants grow to a good size the first year, and an idea can be formed as to which are likely to be the best, there being usually considerable variation, and the worst can be removed. The others can either remain for affording produce the following year, or be taken up and planted at wider intervals for forming a permanent bed.

**Cannas and Hedychiums (Subscriber).**—The plants require practically the same treatment in pots—that is, substantial turfy loam with an admixture of wood ashes and crushed bones; a light position in a warm greenhouse having a genial atmosphere; adequate root moisture, the supplies to be increased with increasing growth, affording clear liquid manure when the pots are filled with roots, when it is not easy to give too much water; cleanliness of foliage by occasional syringings, reducing the water supply in the autumn, and keeping the soil dry in the winter. Plants in small pots should be transferred to larger before the roots are closely matted. Cannas flower well in from 7 to 9-inch pots; Hedychiums as a rule requiring a little more rooting space. The soil must be firm.

**Border under Trees (A. G.).**—Nothing succeeds so well as a bordering to walks or for covering the ground under trees as Ivy. The common or Irish Ivy is extensively employed for edgings in some of the London parks and gardens, and neatly cut once a year in late spring, a

fresh and good appearance is maintained. The soil should be dug and enriched if needed before planting, and the better it is the more quickly the Ivy will grow. In choosing plants take care they have good roots, long trailing Ivy plants with few roots seldom growing well, and many die. The growths may be pegged down to form a border of any required width, and can easily be kept within bounds with the shears. Hollies grow well under trees, especially the broad-leaved Hodgins or Shepherd's, Ilex Hodginsi and I. Shepherdi, when the soil is suitable. So do Rhododendrons and Aucuba japonica, though they do not succeed in all districts. The Evergreen Privet, Ligustrum japonicum, grows well under trees in any ordinary fertile soil. Plant any of those mentioned that grow well in open positions in your garden. The present is a good time for planting them, also Ivy.

**Violets in Frames** (*Young Gardener*).—The method which you have been instructed to adopt of "planting single runners of Violets in cold pits in October" is not the best for affording a good supply of blooms in winter. We have seen stout runners with good crowns inserted an inch or two apart in boxes of light soil kept moist in a warm light house afford blooms plentifully in a few weeks, but no such results could follow in a cold pit. Only failure could be expected by the plan you describe, but as you acted "under orders," obviously the fault does not rest with yourself. Rooted offsets should be planted in good soil in the open air in April, the runners suppressed, red spider subdued, and strong plants with bold crowns will be produced by autumn for establishing in pits or frames before winter for flowering during the dull months of the year, the supply largely depending on the weather when no heat from fermenting materials or otherwise is afforded. A hundred times more flowers will be produced by this method than by the one you have been instructed to carry out.

**Lapageria Unhealthy** (*M. C. D.*).—There are two main reasons why these plants are often in an unsatisfactory state in pots:—1, Close, soil not sufficiently drained, and hence sour. 2, Pots so densely crowded with roots that the plants do not receive adequate support. Lapagerias usually grow best planted out in a bed at least 18 inches deep, the bottom 6 inches being of drainage, broken clinkers and charcoal being excellent, the remainder springy turfy peat and loam, twice the quantity of the former, with a liberal admixture of charcoal, the whole to be pressed down as firmly as the turfy nature of the compost permits. A bed thus prepared can scarcely be made sour, due provision being made for the free exit of water from the drainage, and when the soil is permeated with roots it is not easy to give too much water; until then water must be given more sparingly, yet the soil should never become at all dry. If you prefer growing the plant in a pot, prepare the soil similarly. In the event of your plant not having rooted freely, it will be advisable to remove a good part of the old soil, which will be sour, and give fresh as suggested, thinning out and shortening wiry growths to the best buds you can find, syringing the plant twice or thrice a day according to the weather, to prevent excessive evaporation from the leaves, and so assist the emission of fresh healthy roots, which alone can invigorate the plants. We know of Lapagerias that grow luxuriantly and flower profusely on the north side of greenhouses.

**Transplanting Asparagus** (*J. G.*).—If the ground is well stirred, as you propose, to a depth of 2 feet or 2 feet 6 inches, and ten cartloads of manure are added and well incorporated with the soil, care being taken to keep the good soil on the top, not burying it at the bottom of the trenches nor bringing much, if any, of the poor soil to the surface, it ought, if of a friable nature, to grow good Asparagus. It is well not to move the plants until they are beginning to grow, and if the shoots have pushed a few inches it will be an advantage rather than otherwise. Lift them carefully, preserving all the live roots possible. As the plants are ten to twelve years old they will probably have a number of decayed roots. It is not necessary to lift or preserve any except the live crowns with their shoots and buds and all the live roots attached. Stretch a line where you wish the rows to be, and take out a trench on both sides with a spade, sloping outwards from the line about 9 inches wide and 6 inches deep at the extremities; this will give a ridge which should be knocked down where the plants are to be, so as to form a seat, and so deep that the top of the crown will be level with the top of the ridge. Dispose the roots evenly in the sloping cuts on both sides of the ridge, and cover them with some fine rich soil. Cover with the soil taken out, and place it over the crown to the depth of 2 or 3 inches. Mulch between the rows and over the crowns with a couple of inches of lumpy manure, the remains of spent Mushroom beds, or partially decayed leaf soil. After the plants are in free growth liquid manure may be given between the rows, and continued at weekly or fortnightly intervals up to early September. The first growths will perhaps be comparatively poor, being crippled by the transplanting and consequent disturbance and loss of roots; but after the plants become established they push a strong second growth, and to throw the full vigour of the plants into them the first growths should be cut away when the second are well advanced above ground or beginning to "feather;" and a reservation should be made of two or three of the strongest about midsummer, the other being cut away. If the plants are large more shoots may be left, but crowding is a great evil, and one of the chief reasons why the "produce" is so small as to please nobody. With attention to these matters, and to staking if necessary to prevent damage from winds, there is no reason why the plants should not succeed and afford good heads for cutting next spring.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers.

Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*R. H.*).—Cotoneaster Simonsi. (*G. Mc.*).—1, Sedum carneum variegatum; 2, Doodia media; 3, Polypodium pustulatum; 4, Asplenium palmatum; 5, Adiantum capillus-Veneris; 6, Doodia caudata.

#### FOOD FOR LIVE STOCK.

UPON the sound principle that a farm should be self-supporting, our readers have repeatedly been advised to rely upon home-grown produce for feeding live stock, and to avoid cake bills and other purchased food. We have gone further, and explained how economical in the most comprehensive sense of the term the use of silage, corn, and straw is, and how by a mixed dietary, in combination with general good management, live stock may still be fed to profit. Since the soundness of such advice is questioned, and an inference drawn that it is misleading, we must call to our aid the testimony of some notable

practical agriculturists in support of advice given entirely in the interests of farmers engaged in struggling with difficulties which may prove insuperable where cost exceeds receipts.

Taking silage first of all, many examples could be adduced of the exceedingly strong prejudice of farmers, shepherds, and stockmen against it. The late Mr. Henry Woods, Lord Walsingham's agent, who did so much to prove the value of silage, tells in one of his reports how a shepherd on one of the farms in hand, strongly objecting to using silage, insisted, after a few days' use, that it was "regular upsetting the lambs, as he expected," and that "it would kill a lot on 'em." Persistence in its use under the close supervision of a trusty bailiff answered so well that the lambs were said to be superior to any on the neighbouring farms. Mr. W. A. Darbishire, of Nantle, Carnarvonshire, said in the long hard winter of 1885-6 "Silage was most valuable. I used it for milking cows as a change of diet, for yearling and two-year-old bullocks housed in a covered yard as their main supply of food. I got the sheep to eat it, and in this respect it was most useful and handy. I have not any good statistics as to weight, &c., but some of its advantages are the quickness and handiness with which a large number of beasts can be foddered; no chaffing, slicing, or cooking is required, the food is ready and succulent whenever it is taken out, it is very wholesome food. Beef fed on it is like grass-fed beef as distinguished from stall-fed." This is the evidence of a tenant-farmer.

Earl Powis said that at Powis Castle Farm "we preserved in a silo about ninety tons of green Clover and Rye Grass, put in uncut and weighted with stones. The contents we gave to dairy cows during winter, two feeds per day of silage and three feeds of hay. The quantity of milk was increased, the quality improved, and the cows kept well up in their condition."

From Devon Mr. Alfred Mellor of Otterhead, Honiton, reported the use of 120 tons of silage, of which he said, "My silage turned out good. I fed dairy cows on it, and increased my supply of milk thereby, I should say about 1 lb. more butter per cow per week than I should otherwise have done. Ewes and lambs did well on it with other food." In Warwickshire, Mr. H. J. Sheldon of Brailes House, Shipston-on-Stour, said, "At the end of last June I made a silage stack of about 16 acres Trifolium, with a great deal of shed Oa's in it. After Christmas it came out some first-class sweet ensilage. No waste, except about 7 or 8 inches at the outside, where it was dressed with salt. No mould, or any influence from the outside air, reached beyond that distance. I have given it, in conjunction with other food, to a large number of cow stock, which eat it well, and it does them good."

To these reports we may usefully add an extract from Dr. Voelcker's report of the experiments on ensilage conducted by him at Woburn. Of Grass silage he says, "By these results it is shown that bullocks fed on sour Grass silage of good quality will fatten well, though not quite so well as when fed on a mixture of roots and hay chaff." And of Oat silage, "Taking together the results of the third and fourth experiments, it is clear that Oats cut green and made into silage will produce a very valuable feeding material, and one which in the present instance has proved superior to either roots and straw, chaff mixed, or to hay. Further, the interesting fact has been brought forward that such silage will, if well made, keep perfectly good for at least two years, so that its immediate consumption is not imperative."

There is the evidence of a scientific professor, a landlord, a land agent, and tenant farmers in different counties. To this we add the testimony of Mr. John Walker, author of several works on agriculture. In an article on Ensilage in "Land" he says, "A great advantage in making silage is that one is quite independent of the weather. The wetter the material is when stacked the better, as it presses more easily wet than dry, and

in pressure lies the chief art of making. There are many seasons when half the hay in the country is more or less damaged by rain—at least, it is so far damaged as not to make wholesome diet. This loss might be saved if crops were converted into silage instead of hay. A second advantage is that it leads to the practicability of again bringing stiff clay land into cultivation, and that to a profit. Roots cannot be grown on this kind of land, hence sheep and cattle run short in winter of vegetable diet, which they greatly need. Silage proves an excellent substitute for roots, and is as nutritious, weight for weight, as a Swedish Turnip. Therefore whole breadths of clayey arable land, which is unprofitable to crop in the old-fashioned way, can now be seeded down for one or more years, and the crops be mown and made into silage. Thus farmers are enabled to run a large flock of breeding ewes, the very best paying animals on the farm. A third advantage is that there is not nearly the expense in making silage as in making hay, and this is worthy of especial attention now that labourers are few. The cost of cutting, carting, and stacking only comes to about 1s. per ton, and from 12 to 15 tons of green material are got to the acre."

#### WORK ON THE HOME FARM.

Though the nights have been cold and frosty, yet bright and positively hot days have brought on growth with such rapidity that Wheat rolling has had to be pushed on briskly. Early sown spring corn is now well above ground, and the sowing of mixed seed, Rye Grass, Clover, Sainfoin, and similar green crops is being done expeditiously in all free working soil. Those farmers who pay heed to the mechanical division of soil, as well as to autumn tillage, have now indeed the advantage of those who plough late, and do little or nothing towards soil improvement. Never was the carting of manure for Mangolds done more expeditiously. As fast as it is carted and spread along the furrows, the ridges are split, and the whole field will be quite ready for sowing by the middle of April. Surely no man who has once experienced the keen pleasure of being well forward with all seasonable work can ever afterwards lag behind. Depend upon it, in this, as in other things, it becomes very much a matter of habit. We need not dwell upon the attendant advantages, they are so obviously apparent.

Pasture rich in fertility, from which live stock have been withdrawn all winter, is now so forward in growth that the cows go out four or five weeks sooner than was possible last year. The relief of this is great both to labour and to hayricks, and the improvement in quantity and quality of the milk is alike notable. Very different is the appearance of such well managed pasture to that which is left to chance and seasons. No doubt all growth of herbage is affected by seasons, but starved exhausted pasture is always backward in comparison with that which is in a high state of fertility. Mark such lessons of the seasons, apply their teaching to practice, and reap the reward which attends intelligent earnest work.

Glad were we recently to see the west wall of a farmhouse clothed with the well trained, well pruned branches of some Plum trees. They were in full bloom, which was well protected by sheeting rolled up by day and let down over a stout framework of deal scantling by night. All such space should be turned to account for fruit, either Plums, Pears, Apples, or Cherries; preferably for Pears, which under good management are most profitable.

#### REMARKS.

26th.—Sun shining through thin cloud all day; lunar halo in the evening.  
27th.—Occasional cloud in the morning; almost cloudless afternoon and evening.  
28th.—Almost cloudless throughout.  
29th.—Almost cloudless throughout; lunar halo in the evening.  
30th.—Slightly foggy till 10 A.M.; sun shining through thin cloud or haze in morning clear afternoon and evening.  
31st.—Warm, and almost cloudless.  
1st.—Foggy till 10 A.M., then bright and hot.  
A rainless week of bright sunshine; warm days and clear cold nights. The ninth consecutive week with temperature above the average.—G. J. SYMONS.

MUCH earlier than usual have the blossoms of fruit trees expanded under the influence of the long-continued sun and the abnormal warmth of March and early April. True, there have been cold nights with frost on many occasions, amounting in some localities to 9° or 10°, perhaps more, but the cold appears to have had little retarding effect on the expanding buds. Cherry and Plum trees were wreathed with blossom more than a week ago in the neighbourhood of London, but their spring beauty is over at a time when it usually begins. The flowers of several Pear trees—in fact, the majority—are fully expanded, and some fading. Captain Daubeney has sent us a photograph of a standard Jargonelle tree, taken at Cheltenham on the 3rd inst., densely crowded with developed blossom. On the 1st inst. we had Josephine de Malines fully expanded, and on the 3rd inst. the earliest Apple blossom, Red Astrachan, in full beauty, quickly followed by Duchess of Oldenburg, while Cox's Orange Pippin, King of the Pippins, and several others are expanding.

Seldom has the blossoming of fruit trees been so advanced at the present date as it is this year. It is three weeks earlier than last year, and a month in advance of 1891. Seldom, too, have fruit trees been more densely covered with flowers and expanding buds. The light crop of fruit on many trees last year enabled them to prepare for the present bountiful display in storing nutrient matter that would have otherwise been expended on the fruit, and the dry autumn had a wholesome effect in maturation. Not one kind of fruit, but, generally speaking, all kinds, are unusually floriferous, and should even a tenth part of the blossoms set on many trees they would be distinctly overlaid with fruit. But it by no means follows that such will be the case. Crowded blossoms mean in the case of many trees weak blossoms, and apart from that a good deal of the blossom that is now so beautiful cannot produce fruit, for the essential organs are destroyed; but so far as we have found there are still more of the flowers that the frost did not injure, and the promise of fruit at the present moment is good. Perhaps it would be better if the flowers were fewer, and consequently stronger, on many trees, as we have found on more than one occasion that thinning the blossom buds on certain trees and branches has had a distinctly beneficial effect. Anything like a general and systematic thinning, however, is for obvious reasons impracticable, and the blossom must simply take its chance on the majority of trees.

It does not by any means follow that the trees which are the first to expand their flowers will on that account fail to bear fruit. It is not the time of blossoming that determines the crop, but the character of the weather at the time and immediately after that is the great determining factor in fruit production, whether the blossoms are early or late. It would not be in the least difficult to adduce instances of the earliest blossoming trees bearing well while those which flowered later were fruitless in summer, for this has often been the case.

We now desire to say that there are trees in hundreds of gardens that may and ought to be relieved of the pressure of blossoming. We mean trees which have been recently planted and the reverse of luxuriant. Many there are almost all over the country in which nearly every branch terminates in a blossom bud. These terminal clusters should be removed—cut back to a

wood bud if an extension of growth is desired. Failing this aid trees innumerable that have come under our notice cannot become thrifty, profitable fruit bearers, but must degenerate into mere pomological pigmies. To bush trees and pyramids, cordons, or fan-trained wall trees the remarks apply; if the terminal bud produces blossom free growth is arrested. Four years ago a gentleman planted a number of cordon trees and followed the instructions "not to shorten them" too literally. The advice given was good in the case of those which terminated in growth buds, and they are fine trees now, whereas those which terminated in blossom buds and these allowed to remain are stunted and spoiled, the blank wall spaces affording unmistakeable evidence of the error that was committed in allowing the terminal fruit buds and clusters to remain. The time is appropriate for drawing attention to this matter, in order that similar mistakes may be prevented.

We have seen many pyramid Pears and bush Apples, planted last autumn and during the present spring, every branch of which—and most of them are mere stubs—terminates in a cluster of blossom. They are trees that we should not have chosen, and the only way of making them thrive is to take off the end of every branch, and as the season advances give liquid manure to and mulch over the roots. This may possibly have the effect of forcing free growth, but if left as they are they will soon be worthless miserable little starvelings, exhausted and worn out, a deplorable case of fruit tree infanticide.

The mention of liquid manure reminds of the great use it may be to many somewhat weak and extremely floriferous trees during the blossoming period. The Cherry tree in a farmer's garden always blossomed, but if the fruit set it never developed, but was cast prematurely, until he was advised to pour several pailfuls of liquid manure into the ground from the stem to the spread of the branches when the blossom buds were advancing. The result was altogether satisfactory, and he has since, and for several years, extended the practice to other trees that were more or less enfeebled, with the best results. They are now healthy, and only under the most inclement weather influences do they fail to yield good crops of excellent fruit.

There are trees innumerable growing against walls—trees the reverse of vigorous—that would be undoubtedly benefited with liquid manure at the present time. It would have a tendency to assist the blossoms in setting, and could not fail to invigorate the trees and support the fruit. Where the soil is very dry, as is the case now near many a wall, it is an excellent plan to first afford clear water copiously and then follow with more nourishing liquid food. Pouring liquid manure into very dry soil is, to say the least, wasteful, and it cannot then have the hoped for effect. It is the extreme dryness of soil near walls that causes many roots to seek for moisture in the subsoil.

It is to be understood that the trees for which liquid manure is advocated at the present time are those which are established in their positions. It is desirable to allow young trees to make fresh root growth before stimulants are afforded, and then only those in a more or less stunted condition are materially improved by the application, but the benefit to these may be great.

No doubt it is true that whatever may be done fruit crops are liable to fail. We have had rain and hail, frost and snow, with destructive blizzards in April and May, and it is, notwithstanding the brilliant spring we have enjoyed, within the bounds of possibility that we may have similar unfortunate visitations again; still, should this be so, those who have done all that was possible to insure success will be none the worse for the effort but better, for they will have no self-reproaches, and every right-minded man must rest the more contented in misfortune when he feels that he at least has done all he could within his skill and means to attain the object in view, for he then knows he has done his duty.

## HARDY FLOWER NOTES.

THE brilliant sunshine of the past few weeks has hastened our spring flowers so rapidly that it is impossible that the publication of these notes can keep pace with the rapidity with which these beauties of the garden have come to delight us, and have as quickly passed away, for spring flowers, as a rule, cannot endure for long the bright weather we have experienced. Thus it is that we are compelled perforce to speak of flowers which ere this appears will have doffed their gala costume of purple or blue or golden yellow, and will have assumed their work-a-day dress of sober green.

The earlier Daffodils have come and gone, to be succeeded by those of later bloom, and they have left behind them memories of their trumpets of brilliant gold, of softest canary hue, or of well nigh purest white, drooping with pensive mien, and now we can echo the words of Wordsworth, and say that still

“ . . . My heart with pleasure fills,  
And dances with the Daffodils.”

The earlier Primulas, too, have passed away, but others, with the Primrose and the Polyanthus, some of quaint form, still delight us, while the Alpine Auriculas have not failed to give their tribute of beauty. Fritillarias, with their drooping chequered flowers; blue Forget-me-nots; Anemones, from the deep blue of the better coloured varieties of *A. blanda* to the forms of *A. nemorosa*, Shelley's “fair and frail Anemone.” These, and many more, have crossed the stage of the season, and have given more than passing pleasure, for throughout the year we can never forget these flowers of the early spring, which never pall upon us, and which are the heralds of the long days of summer with their more gaily coloured blooms.

Looking back then for a little, no flowers have given us more pleasure than the *Chionodoxas*, which have this season been unusually beautiful. Unlike many other treasures of the garden, the Glory of the Snow pines not away in our British gardens, but seems to increase in vigour and beauty from year to year. Perhaps the least attractive of all the several species or varieties is *C. cretensis* or *cretica*, which is so inferior to the others as hardly to deserve a place. This, however, cannot be said of *C. nana*, also a native of Crete, and which I have seen for the first time this year. This is a beautiful little plant, with small white and lilac flowers, and growing about 4 inches in height. This is very rare in gardens, and I prize my bulbs very highly. So well known now is *C. Lucilæ* that a detailed notice of it at present is quite unnecessary. As it is, however, now so cheap, and is so easily increased by means of seed, one can only plead for its more extended cultivation. For some time a pure white variety has been in cultivation, but has been extremely scarce. It is hardly to be expected that it will long continue so, as the *Chionodoxa* is now so frequently raised from seed that white varieties are being found in several gardens. So far I have not found any among my seedlings. Beautiful as is the typical *C. Lucilæ*, with its *Nemophila*-like flowers, it must yield place to the more lately introduced and more brilliantly coloured *C. Smolusii*, which is perhaps not distinct enough to obtain specific rank, but is in any case a distinct and superior variety, having its colours brighter and more distinct. A little clump of this at the base of a rockery facing west, but well sheltered from the western gales, afforded me much pleasure when in full bloom. Of a different colour and very distinct has been *C. sardensis*, with bright self-coloured blue flowers, which are very fine in their way. This does not seem to vary as much as *C. Lucilæ*, and a large number of seedlings, flowering for the first time, have presented little if any variation from the type. Distinct also, and one of the most beautiful of all, is *C. grandiflora*, known more frequently as *C. gigantea*, but the former name is more appropriate, as the plant is of neat and good habit. This has large and exquisitely coloured lavender and white flowers. The latest recruit to the ranks of the Glory of the Snow (*C. Alleni*) has flowered for the first time in Britain this year, but it is as yet impossible to compare it properly with the others. It is said by its introducer, Mr. E. Whittall of Smyrna, to be finer than *C. grandiflora*, which it appears to resemble. Another year will, however, enable us to judge of its comparative merits. So far as one can see at present, it is taller than *C. grandiflora*; but I am doubtful if its flowers will be so well formed.

With all the beauty of the *Chionodoxas* we cannot, however, dispense with the early Squills, which give so much interest to the garden, and which have been so fine this year. *Scilla bifolia* is now presenting so much variety that it will hold its own in popular favour. Now that we have dark blue, light blue, white, pale pink, and deep pink flowers we cannot complain of want of variety in this species. In addition we have the superior *S. bifolia taurica*, and I have seen specimens of a variety of *bifolia* which is by competent judges considered a good and distinct form, and which we hope to see introduced this season. *Scilla sibirica* is one of the

“standard” flowers which grows in favour from year to year, and the introduction of a white variety has been hailed with delight by many. This is still at a high price for a *Scilla*, and I have not as yet seen it; but good critics of wide experience speak in the highest terms of its value and beauty. It received an award of merit at the meeting of the Royal Horticultural Society on March 28th. It is of Dutch introduction, but a white seedling has also appeared in a Scottish garden this year.

So frequently is *Scilla bifolia* found growing along with the *Chionodoxas* that it appears surprising that natural hybrids have not been detected. So far, however, as I am aware, this is the case; but what has not been discovered among plants growing wild has been found in this country, for a hybrid between *S. bifolia* and, apparently, *C. Lucilæ* has been found in the garden of Mr. James Allen of Shepton Mallet. This has been named *Chionscilla*, and through the kindness of the raiser I have been gratified by receiving a plant of this interesting hybrid, which appears to be exactly intermediate between its supposed parents, the colour being blue, grained with white, and the tufted arrangement of the centre showing the character of the *Chionodoxas*. There is every prospect of other *Chionscillas* being obtained, and Mr. Allen's success should stimulate others in seeking to raise new flowers.

Beautiful as they are the bulbous flowers do not constitute the sole attraction of the garden, and other plants call for at least scanty notice; and as being of great beauty and at the same time of troublesome reputation the *Androsaces* may be deemed worthy of a little space. They are among the choicest gems of the rock garden, and are well worthy of repeated attempts in cultivation should success not be at first attained. For some time I have been gradually adding to the species in my garden, and severe as has been the past winter all have survived and are in perfect condition. This is due to what is a necessary precaution in this climate, *i.e.*, covering them with a sheet of glass or a slate, slightly elevated above the plant, but so that a free circulation of air may be secured. Cold seems to have no terrors for the *Androsaces*, and this protection from damp is put over them in October and remains until March. Upon the whole I prefer a slate to glass, and remove this on fine dry winter days. The glass seems to forward the blooms too rapidly. The soil used is sandy peat with an abundance of grit. *A. carnea*, which seems to dislike lime, has nodules of granite mixed with the soil, and is surfaced with fine granite gravel. I grow all my plants on terraced rockeries facing west or south-west, and several have been very beautiful, among the most attractive being *A. chamæjasme*, with pretty flowers, which on opening are white with a yellow eye, this eye becoming crimson and the petals passing off to rose. *A. sarmentosa*, *A. lanuginosa*, and some others are also well worthy of notice.

Very pretty, too, and forming a close carpet of green, surmounted by spikes of light blue flowers, has been *Veronica nummularifolia*, for which I have been indebted to Rev. C. Wolley Dod on the occasion of a well-remembered visit to his delightful garden. I know nothing of this plant, of which I have seen no record, but it is one I highly appreciate, coming into flower as it does here in the end of March and growing in ordinary soil on the terrace of a rockery, and covering itself with its fine and attractive flowers.—S. ARNOTT.

## PRACTICAL HINTS ON MELON CULTURE.

CONTINUING my remarks on this subject from page 268 I may say that before planting I always take especial care to have the top of each mound slightly above the inner wall of the bed, so that when the final earthing is given the collar of each plant is still a little above the surrounding soil. By taking this precaution there is much less likelihood of canker giving trouble than when the surface of the bed is quite flat by the time earthing is completed. The soil forming the mounds should be rammed moderately firm, and somewhat flat on the top; if made quite conical in shape great difficulty is experienced in watering thoroughly when once dry.

Before turning out the plants see that the balls are thoroughly moist, otherwise the fresh soil will become too wet in the endeavour to effectively moisten the balls after planting. Take care not to bury the stem when planting; press the soil firmly around the balls, and just cover the surface with a little fresh soil. A stick should be placed to each plant, and be tied to the bottom wire of the trellis; it is then an easy matter to loosely secure the growth to it as it advances, and thus avoid the annoyance of having promising young shoots broken.

The process of earthing up should be carried out more gradually with early Melons than with later ones, as the roots are then very susceptible to a check of any kind, and when a thick layer of soil is placed over them they make less progress, through not

getting the full benefit of the limited amount of light and sunshine which we have in the early months of the year. I find the plants thrive much better if the earthing is done on four separate occasions for early Melons, and on two or three for later ones. In all instances the soil employed should be warm and moderately dry. When in this condition it ought to be rammed firmly, but should the plants through any cause be somewhat stunted in growth the soil may with advantage be left with but little ramming. I always like to give the final earthing by the time the fruits are as large as a hen's egg, so that the roots may thoroughly permeate every portion of the soil by the time the fruits approach maturity.

The best method of stopping and training to adopt is a matter which has undergone much discussion, and the various systems advocated have each their special advantages, provided they are well carried out. Taking all points into consideration, I believe the practice of securing one crop of fruit from each set of plants, then uprooting them, and replanting with a fresh batch, is the best in the majority of instances; but where only one house or pit can be devoted to Melon culture, I would strongly advise one set of plants to be grown through the entire season. By so doing a regular supply of fruits may be maintained by continually laying in fresh growths and setting a few flowers when the preceding fruits have completed their first swelling. This system is also well adapted for structures in which a large amount of roof space is at command; and, moreover, the highest obtainable flavour in Melons is developed under this system of culture. When carrying out this method, stop the leading growth when it has advanced 3 feet from the bottom wire, and the side shoots at one leaf beyond the fruit. The leader may then be allowed to extend for another 3 feet, and the laterals treated in the same way as the first set, then by the time the allotted space is covered, some of the old shoots at the base of the plants will be ready for removal, their place being filled up by young growths, which under good cultivation form readily enough in all directions. By keeping these thinly disposed, moderately strong wiry-looking shoots are obtained which are much less likely to be affected by canker than the strong growths on young plants.

When the system described above is followed the laterals which form near the first wire of the trellis should be stopped to one leaf, for they generally produce flowers which open so much in advance of others that there would be but little chance of obtaining a good crop of fruits, if these early flowers were retained and fertilised, unless the setting of other flowers were delayed till this pair of fruits had completed their first swelling. All other laterals should be allowed to grow for a time until it can be clearly seen that four or five fruits in the same stage of development have been obtained; every alternate lateral should then be cut away, and one or two leaves (according to the space at command) be retained beyond the fruit. Should any fruit at this early stage show signs of growing strongly at the expense of others on the same plant, tie the shoot carrying it downward so as to cause an abrupt bend below the fruit and thus check the flow of sap. When a proper balance has been restored secure the shoot again in its proper position. Simple attentions of this kind performed at the right time invariably account for the difference between full even crops and uneven or light ones.

The subsequent attention required in the way of stopping is to remove or stop at one joint laterals which are being formed in parts where there is no room for their development, always taking care to avoid stopping the whole of the young growths at the same time and to have a little growth constantly going on on all shoots carrying a fruit as a means of keeping up active root-action and preventing the production of tough-skinned badly ripened fruits.

When stopping is performed in wet or dull weather an equal mixture of lime and soot should be placed upon the wounds made by pinching, which should always be done with the finger and thumb in preference to the knife.—LABOR OMNIA VINCIT.

(To be continued.)

### EARLY BEDDING.

ABOUT this date, earlier or later according to state of weather, I plant out all those bedding plants that are not tender, such, for instance, as *Königa variegata*, *Veronica Andersoniana variegata*, *Pentstemons* and *Calceolarias*. Where it is possible to put out these plants in their places thus early, it facilitates the planting of tender things at the usual time. Further, a certain amount of frame space is thus left clear for other plants, and there is no labour wasted in watering and other necessary attentions. The transplanting of *Calceolarias* at this period saves much work. Until I planted *Calceolarias* in this way they could not be depended upon to live, now they thrive exceedingly well. Another plant which caused much

annoyance by dying off during the early autumn months is *Chamaepeuce diacantha*; and since I have planted early no plant could thrive better.

For the past few years Dahlias have also been planted on the beginning of April. The evolution of this practice was in this wise. Cactus Dahlias are late in flowering when propagated from cuttings in the spring. The tubers of spring-struck plants, moreover, are apt to decay during the winter. The original stock plants of Juarezi happened to be put out in a warm position, where for several years the plants lived undisturbed. These invariably flowered early and most abundantly, even in seasons when hardly a flower could be obtained from young plants. For two years I started all the old tubers in cold frames and planted them out at the usual time. Then I tried some single varieties with buds started, planted out in the first week of April, and since that time I have planted all our stock at the same period and in the same way. It will be understood that exhibition blooms are not looked for, but only flowers for cutting and plants to give a good decorative effect.

I adopt the following method of planting the Dahlias. The tubers are cut or pulled into good sized pieces, each with two or three buds started. The stations which the plants are to occupy are then marked off. A hole of sufficient size to allow a covering of 3 or 4 inches of soil above the root when planted is made at one end of a row. The soil from the second hole is placed over the first plant, then that from the third is put over the second, and so on. The growths come up strongly about the end of May. When large enough two shoots of each plant are pegged down, and the superfluous growths are removed. In addition to securing a healthier, more early, and free-flowering plant with tubers which keep without loss, the system has these advantages. There is no necessity to start plants in hothouses in order to produce cuttings, because the latter are not required. There is no potting, nor space occupied in houses or frames, and the work of planting is done quite as expeditiously and with less pressure than at the usual time. Where only a few plants are cultivated the latter feature is not of course of much account; but when, as in our own case, some 500 plants are required, the difference in every respect is marked. Two years ago I left our plants in the north with their earliest flowers open, and did not see a single bloom during a flying visit, which embraced parts of Kent, Essex, Surrey, and Middlesex. A visitor from the south last year expressed surprise to see Dahlias flowering in Scotland at a time when no flowers were to be seen in the south of England.

The practice of pegging down the young shoots is also a good one. Last year I was complimented by a well-known horticulturist on the fine plants of Tom Thumb Dahlias I had in a large clump. He was somewhat surprised when assured they were ordinary sorts which had been pegged down.—B.

### CHASSELAS NAPOLEON GRAPE.

THIS Grape is not, according to the leading French authorities, synonymous with *Panse Jaune*. Mr. Etienne Salomon says Chasselas Napoléon is not a Chasselas, and its real name is *Bicane*; origin, the Department of Cher; very vigorous, pretty fertile, very large; bunch loose, spreading; berry ovate, very large, amber-white; midseason.

*Panse Jaune* is described as follows:—Not a Chasselas; origin, Provence; very vigorous, fertile; bunch large, long, with shoulders, not compact; berry above medium size, ovate, greenish-white, turning to yellow on maturity; indifferent setter; season late.—HELENEVELD.

Now that all has been said that can well be said in relation to this old French Grape, may I venture to suggest to the Fruit Committee of the Royal Horticultural Society that all this bother might have been avoided had that body, at the time the Grape was submitted to it, before hasting to award a first-class certificate, rather have held any award over until full and complete inquiry had been made as to its origin, character, and general fitness for the honour proposed to be granted?

It is rather a serious thing to make awards of this kind to anything, for its value is regarded by outsiders oftentimes with feelings of greater concern, perhaps of reverence, than exists within the Committee; and such an award to a Grape, and especially what is now proved to be an old and oft-tried and oft-rejected Grape, renders such an award all the more serious. The moral is obvious: neither to oblige a neighbour, or to gratify a hurried fancy for anything new or old, should there be too much haste, and if all such awards were provisional for three months prior to confirmation or otherwise, it would be all the better.—VITIS.

## PROSPECT OF EARLY ROSES.

IN reply to "Suburban's" inquiry on page 280, Roses here are very early. If fine bright weather still continues I think probably Maréchal Niel, Gloire de Dijon, Lady M. Fitzwilliam, Niphetos, and others will be fully expanded in a fortnight's time. Some may be earlier from a south aspect.—G. F., *Trafalgar, Salisbury.*

## CLIMBING LA FRANCE ROSE.

AN American contemporary, *Gardening*, in a recent issue to hand, publishes an illustration of the climbing La France Rose, which to all appearances is a charming variety. The illustration was prepared from a photograph taken in Peter Henderson & Co.'s nurseries last November. The variety is described as being "a strong, stout climber, healthy and with fine foliage, and it bears large fine blooms. But it has every appearance of being a somewhat shy bloomer. Commercially, perhaps it may not be grown for cut flowers, but amateurs will like to have a plant or two of it in their greenhouse to run up the rafters in company with Gloire de Dijon, Lamarque, and Maréchal Niel."

## THE ROSES OF OUR CHILDHOOD.

No flowers seem fairer to our vision or our remembrance than those which are links between the present and the past. During the last six months I have introduced into my garden at least seventy modern varieties of the Rose: Hybrid Perpetuals, Bourbons, Noisettes, and Teas; Roses from Austria, Persia, China, Japan, France, Holland, and even from America; but the old red Rose (which has grown from time immemorial at the corners of the garden), so loved of my father, an ardent horticulturist, has been lovingly retained.

I fear that many of our beautiful old-fashioned Roses are fast disappearing from the regions of cultivation. There are however—thanks to the efforts of our greatest rosarians—some striking exceptions to this general rule. Among these I may mention the Harrisoni, the Austrian Copper, the Persian Yellow, and the exquisitely fragrant "Provence" Rose. That one fine variety of the last-mentioned species should ever have received the name of "Old Cabbage" has excited the indignation of the Dean of Rochester, who, in his book on the Rose, suggests that the title in question may have been invented by a tailor, though I think it more probable that it was created by a vegetarian. No such name, most fortunately, has been applied to the White Provence, which Mr. Cranston describes in his book on Rose culture as the "purest in cultivation." Unlike many modern and more formidable white Roses—such, for example, as the White Baroness and Merveille de Lyon (for the most part partaking of the character of their venerable parent, the Baroness Rothschild)—the White Provence, also called "La Blanche" or "Unique," is remarkably fragrant, this indeed constituting, quite independently of its beauty, a supreme attraction. In my garden, therefore, I have given this Rose a central position, with Rosa Harrisoni, for the sake of artistic contrast, on either side.

The Moss Rose derives its origin and most of its attributes from the Provence, a fact which must be transparent to any rosarian who has carefully studied and compared their formation. The former came to us originally from Holland; the latter, though bearing the name of a very historical and romantic French region, identified with all that is heroic and chivalrous, is generally supposed to have been of Italian extraction.—DAVID R. WILLIAMSON.

## RHODODENDRONS.

I DOUBT not that "E. M." (page 271) is right in maintaining that these showy shrubs will not thrive in the turfy loam obtainable at Swanmore, because from the excellent description he has given of it, it is quite clear that lime enters largely into its composition; thus it belongs to that class of soils which I stated on page 250 should be strictly avoided for Rhododendron culture. I do not, however, agree with "E. M.'s" suggestion that soils containing only a small percentage of lime are unsuitable, if not fatal, to the growth of Rhododendrons, simply because nearly all soils contain lime in small quantities, and I doubt if any fertile soil in this country could be found totally destitute of it. Yet in many instances these popular shrubs flourish in the natural soil, and develop into splendid specimens.

In some parts of Kent, Surrey, and Wiltshire I am acquainted with fine banks of Rhododendrons which may have been planted in prepared soil, but the roots have long since found congenial quarters in the natural soil around. Now it is evident these soils cannot be entirely destitute of lime, because Hops, fruit trees of all descriptions, and even Vines grow well in the same soil, which they would not do if a small percentage of lime were not present. This, I think, proves that it is only when soils are largely impregnated with lime that they are wholly unsuited to the growth of Rhododendrons, and that with liberal additions of the decaying refuse described in my previous note may be rendered quite suitable.

In the soil at Warwick they grow freely enough when well established if treated liberally, but there is some difficulty in securing good growth in the early stages. This I attribute to the fact that the soil is rather

light and poor; being also thoroughly well drained, the plants suffer from drought if not given special attention in watering. When, however, the roots have pushed well into the surrounding soil, with frequent top-dressings the plants flourish. Before these top-dressings are given I find it is a good plan to loosen the surface of the soil with the point of a fork. Although this practice has been frequently condemned, I am convinced it is of great benefit to the plants, especially when in a young state, as it enables the rains to percolate and carry nutriment to the roots. I was led to adopt this practice by noticing how well a few young plants thrived when planted in a mixed shrubbery which is forked over each spring. I thoroughly agree with "E. M." as to the efficacy of cow manure as a top-dressing for Rhododendrons, but unfortunately I am not able to obtain it in sufficient quantities for that purpose.

In conclusion, I may say that I do not dispute there are many soils so impregnated with lime as to make Rhododendron culture an impossibility in them, and where this has been proved to be the case they should be planted entirely in peat, leaf soil, or any refuse I have previously recommended; but I am also convinced there are many instances where they would flourish in the natural soil if it were properly prepared. It is an easy matter for anyone to find out if they are so grown anywhere in their locality. If not, let them try a few plants for themselves, we should then have the culture of one of the most showy of hardy shrubs greatly extended.—H. D.

## THE LARCH DISEASE.

I HAVE not noticed any correspondence in the *Journal* respecting the Larch disease for some time now. I should be glad to know if that means that it is not so bad in the country generally. My reason for asking is that it is very bad in this district, and has been for several years now, whole plantations being destroyed by it. In some parts it appears to be caused by the Larch aphid or bug—*Chermes Laricis*; in others by the Larch canker, which I suppose is caused by the parasitic fungus. It is so bad that planters are hesitating very much with respect to continuing their annual planting of Larch.

I should also be glad to know if the Abies Douglasi has been planted extensively with a view of superseding the Larch anywhere, and if it has been a success; also its value as a timber tree compared with the Larch, as it appears to grow very well here, although we have not yet planted it extensively.—R. C. WILLIAMS, *Crosswood Park, Aberystwith.*

## POPULAR HALF-HARDY ANNUALS—SOWING THE SEED.

WHAT a fine floral display can be produced in the flower garden during the summer and autumn by sowing seeds of annuals at once where the plants are intended to flower. Beds may be filled exclusively, and with admirable effect too, with the best and most distinct and telling varieties of the Calliopsis, Godetias, Cornflower (*Centaurea Cyanus*), Alonsoa Warscewiczii, Nemophilas, Nigella damascena (Love-in-a-mist), Limnanthes, Clarkia (Carter's Morning Glory), Gypsophilas, Gaillardias, Collinsia, Eschscholzia compacta, Phlox Drummondii, Asters, Stocks, dwarf Tropæolums, and Zinnias.

For sowing in patches in herbaceous borders Shirley Poppies, Malope grandiflora, Larkspur, Lupinus, Prince's Feather, and Love-lies-bleeding may be added to the above list. As the descriptions and average heights of all of the plants mentioned above may easily be obtained from the trade list of any leading seed merchant there is no occasion to give them here, further than saying that Calliopsis Drummondii, C. tinctoria, and C. Burridgei, Godetias Sutton's Ladybird, Lady Albemarle, and Apple Blossom should be included in every list of select annuals.

Individual beds filled with Alonsoa Warscewiczii compacta, a half-hardy annual attaining to a height of 1 foot, and having dark green lanceolate serrated foliage and racemes of bright scarlet flowers, are very telling in effect when contrasted with surrounding beds of Calliopsis Drummondii, yellow; Godetia Ladybird, flowers pearly white, plants 6 to 9 inches high; Collinsia grandiflora, purple and blue, height 1 foot; Tom Thumb Nasturtium "Aurora," varying in colour from primrose to pale pink; N. cœruleum roseum, flowers rose, tinged with blue; Phlox Drummondii. Stocks, Asters, and other things. The beds having been previously dressed with some light, well-decomposed manure, dug and trodden, should be raked before scattering the seed very thinly on the surface. The soil should then be scratched over with a fine-toothed rake, and then watered through a fine-rose can, repeating the watering every afternoon in the absence of rain until the seedlings appear. Thin the young plants sufficiently to allow of their making a sturdy and consequently more floriferous growth than would otherwise be the case. Where the soil is of a stiff nature it will be advisable to scatter a little fine, light, rich mould over the surface before and after sowing the seed, finishing off with a firm, even surface. Waste soil from the potting bench passed through a quarter-inch mesh sieve would answer this purpose admirably.

Slugs frequently work havoc among young plants of annuals, therefore a sharp look-out should be kept for these destructive pests in the evenings just before dark, or afterwards with the assistance of a bull's-eye lamp, when they will be found engaged in the demolition of the plants, and needless to say the slugs should be collected and destroyed. If the plants are dusted over with a mixture of lime and soot when damp it will preserve them from being injured in the direction indicated.—H. W. WARD, *Longford Castle.*

## ODONTOGLOSSUM NÆVIUM MAJUS.

THIS is one of the most beautiful of all the New Grenadan species, and it is not difficult of cultivation. Although not a very robust grower, yet with ordinary care and attention it may be increased in size year by year, and grown into neat little specimens. This species enjoys a position as near the roof glass as possible, both for the sake of light in winter, and also for an abundance of air in summer. It must be closely shaded during the summer, and cannot be kept too cool. It requires an abundant supply of moisture, both in the atmosphere and at the root, frequent syringing on bright sunny days being very beneficial. Although it will not stand with impunity the same cold in winter as *O. crispum* and other occupants of the very cool houses, yet it must not be coddled, a minimum of 45° will suit it admirably.

It should be potted in the usual peat and sphagnum mixture, in the proportion of two to one respectively. Use clean pots and fill with about two-thirds drainage, covering this with a layer of moss to prevent the earthy particles of the peat being washed downwards among the crocks. The plants should be raised fully an inch above the pots, which must be only large enough to allow about an inch of compost around the plant. Wrap a little of the peat round the roots close under the base of the bulbs. The plant may then be easily fixed in the exact position required by filling around with compost, and pressing it firmly into position, introducing at the same time a few small pieces of broken crocks or charcoal. Then a few "points" of moss should be dibbled in, and all trimmed off neatly in the shape of a cone. This will be found a better and more expeditious way than any other, because of ease with which the plant is secured, and the impossibility of its rocking—a matter of great importance in the well-being of any Orchid.—H. RICHARDS.

## CULTURE OF CALANTHES.

THESE plants should be potted at once if not already done. In potting *Calanthes* it is not necessary to elevate the pseudo-bulbs above the rim of the pot, indeed they thrive much better when they are kept below the rim. Some growers recommend growing these plants in sphagnum moss, but after having given it a trial for two successive years I have come to the conclusion that they thrive much better in a more substantial mixture. The compost I find most suitable for them is fibrous loam, lumpy peat, charcoal, cow manure, and a little sharp sand. The pots should be half filled with crocks, with a layer of moss placed over them to keep the soil from washing down amongst the drainage. Fill the pots with the compost before mentioned, burying the pseudo-bulbs half an inch, or thereabouts, placing three large bulbs or five smaller ones into an 8-inch pot, according to their strength.

Another very good method of growing these plants is to prepare a number of 9-inch pots by half filling them with crocks as mentioned, and put a 5-inch pot in the centre of each, placing moss between the pots. When the foliage has died away, which generally takes place about the time the flowers commence to open, the centre pot may be removed and *Adiantum cuneatum* or some other Fern substituted in its place. Where a variety of plants are in request for house decoration this method of cultivation is more especially to be recommended on account of the pleasing effect thus produced and the great length of time the flowers remain in perfection.

After potting the plants should be placed in a position as near the glass as possible, and in the full sunlight in a warm house. I grow mine in the early Melon pit, the strong heat and plenty of atmospheric moisture proving beneficial to them. The process of watering must be carefully performed; in fact, a slight syringing at closing time would be quite sufficient till the new roots have taken well hold of the compost, after which water may be administered more freely. After the flower spikes become visible liquid manure, such as drainings from the cowsheds, to the extent of one part to three of water, may be applied every other day with satisfactory results, it being much better to apply it little and often than to risk injuring the plants by giving too strong an application. The foregoing remarks apply only to the *C. Veitchi* and *vestita* varieties.

*Calanthes* are subject to attacks of various insect pests, brown scale being especially troublesome; scale should therefore be

diligently and continually sought after and destroyed, otherwise the foliage will quickly become disfigured, and present an unsightly appearance.—GEORGE PARRANT, *Ashby Lodge Gardens, Rugby.*

## AERIDES VANDARUM.

THIS *Aerides* has been in cultivation for many years, but is still a somewhat rare plant. It was figured in the "Botanical Magazine" as long ago as 1857 under the synonym *A. cylindricum*, a name under which it is still to be met with. In general appearance it resembles *Vanda teres*, but has longer and more slender leaves. These are terete, about 6 inches long, and are arranged alternately on the stem about 1 inch apart. The flowers are produced singly or in pairs on short spikes springing from the side of the stem opposite the leaves. They are about 2 inches across

FIG. 56.—AERIDES VANDARUM.

and of the purest white, except for a slight tinge of rose on the inside of the column. The sepals and petals, which are spreading, wavy, and crisped at the margin, are nearly unguiculate. The lip is three-lobed and rather remarkable. The front lobe is very irregular and twisted; the side lobes are large and stand straight up. The spur is about 2 inches long, of a greenish colour tipped with red.

The plant may be grown in baskets or cylinders or on blocks of soft wood, the last being preferable. It requires a stove temperature and moist atmosphere with plenty of water during the growing season. In winter it may be kept a little drier, but not to such an extent as will cause the leaves to shrivel. *A. vandarum* is an Indian species, and flowers during the winter or early spring. Fig. 56 represents it.—A. B.

**EVENTS OF THE WEEK.**—The principal event of horticultural interest of the ensuing week will be the Ghent Quinquennial Exhibition, which, as mentioned in another paragraph, opens on the 16th inst. The Linnean Society will meet on Thursday, 20th inst., and there will be the customary auction sales.

— **THE WEATHER IN LONDON.**—The past week has been dry and for the most part sunny. Tuesday, however, was dull and cold, north-east winds, prevailing. Similar weather continued early on Wednesday, and at the time of going to press it is fair but rather cold with northerly winds.

— **THE WEATHER IN THE NORTH.**—The past week has been throughout dry, the days warm, one or two extremely so for the season, with frosts of 2°, 4°, and 6° on three nights. The barometer fell somewhat during the past two days, but is still very high, and although this morning, 11th, is dull there is no appearance of change. Hedges are far advanced into leaf, a month ahead of last year.—B. D., *S. Fethshire*.

— **UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.**—The monthly meeting of this Society was held on Monday evening last at the Caledonian Hotel, Adelphi Terrace, Strand. The chair was occupied by Mr. George Kelf. The usual business was transacted, five new members being elected and three others nominated; S. M. Segar, Esq., also became an honorary member. Two members only are on the sick fund, showing the Society to be in a very healthy condition. The usual vote of thanks to the Chairman ended the meeting.

— **SUNSHINE.**—For the last five weeks the daily amount of bright sunshine over the greater part of the midland and eastern counties varied from seven and a half to seven and three-quarter hours, the proportion of its possible amount being in nearly all cases over 60 per cent. At the south coast stations the mean daily amount was about an hour greater than in the inland districts, the per-centage for the five weeks being over seventy, and in some places as high as seventy-two to seventy-three.

— **FLOWERS ON THE STOCK EXCHANGE.**—A daily contemporary says:—"With the arrival of the spring flowers, passengers on the Great Eastern Railway see once more every Saturday what is known on the line as 'the flower carriage.' One of the compartments of the train is filled with Stock Exchange men, each of them carrying in one way or another a number of fresh-cut flowers gathered from their gardens in Essex. These flowers are put up to auction in 'the House' in the course of the morning, the proceeds week by week being sent to one of the London hospitals."

— **FAILURE IN FORCING STRAWBERRIES.**—I shall be obliged for any information that can be given in regard to Strawberries in pots. I force several hundreds in Peach houses, and this season Sir J. Paxton has shown very little bloom; instead of the crowns remaining plump they have split up into three or four growths, and nearly half are without flower trusses. The roots are healthy and foliage good. I take the runners from young plants put out for the purpose, and peg the runners into the fruiting pots. I shall like to hear how others are showing this season.—J. BOWLER.

— **THE WEATHER DURING MARCH AT RIPLEY, YORKS.**—This was a memorable month, yielding a maximum of sun and a minimum of rain. It opened rather roughly, but in a few days settled down to beautiful, bright, calm weather with frosty nights. Although we have registered as much as 15° of frost during the month all fruit blossom has escaped injury owing to comparative dryness of the atmosphere. The total rainfall amounted to 0.58 of an inch, which fell upon five days. The greatest daily fall occurred on the 1st, when 0.25 of an inch was registered. Mean reading of barometer, 30.01. Mean maximum temperature, 53.7°; mean minimum temperature, 28.9°. Mean temperature of month, 41.3°. Highest maximum temperature, 65° on 20th; lowest minimum temperature, 17° on 19th. Hardy fruit prospects are exceptionally good in this district, provided that frost will only retire at an early date.—J. TUNNINGTON, *Ripley Castle Gardens*.

— **GARDENING APPOINTMENTS.**—Mr. Geo. Garner, for the past seven years gardener to Mrs. Braddyll, Amberwood, Christchurch, has been appointed gardener to E. A. Drummond, Esq., Cadland Park, near Southampton.

— **DUTCH FLOWERS.**—During the past week immense quantities of Hyacinth flowers have been received from Holland, and have realised comparatively low rates. The white and pink flowers, as a rule, obtain the highest prices in the Metropolis.

— **INTERNATIONAL JUBILEE HORTICULTURAL EXHIBITION, LEIPSIG.**—It is reported that "A great Exhibition under this title will be held at Leipzig from August 25th to September 5th next, to celebrate the fiftieth anniversary of the foundation of the Leipzig Gardeners' Society."

— **DEATH OF MR. W. R. M'KELVIE.**—We regret to record the death, on the 2nd inst., of Mr. William Ross M'Kelvie, Superintendent of Public Parks and Cemeteries in Dundee. The deceased, who was between sixty and seventy years of age, was appointed to his Dundee office in January, 1863.

— **MR. ROBERT MACK.**—This gentleman, a well known Northern Rose grower, has been placed upon the Commission for the North Riding of the county of Yorkshire on the recommendation of the Lord Lieutenant, the Marquis of Ripon. Mr. Mack is the senior partner of the firm of Robert Mack & Son, Rose Nurseries, Catterick and Scorton, Yorkshire.

— **SPIRÆA JAPONICA.**—Supplementary to Mr. Parrant's note on page 253 "G. F." observes:—"I find that this useful plant forces a great deal better when planted for a couple of seasons in any good garden soil. By this method the plants have a good rest. I have some now in bloom with twenty to thirty spikes of flower equal to those imported."

— **RHODODENDRON PRINCE CAMILLE DE ROHAN.**—This is one of the earliest varieties we have, and the colour, French white beautifully spotted with crimson, is pleasing. The flower trusses come in useful for room decoration. The growth of this variety is all that could be desired, being compact and floriferous.—E. M.

— **KENT FRUIT GROWERS' ASSOCIATION.**—The annual general meeting was recently held at Sittingbourne. Among other business conducted a cheque for £50 (second contribution, making £100 in all) was drawn, and directed to be forwarded to the Canterbury Chamber of Agriculture towards the expenses incurred in the proceedings before the Railway Rates Commission.

— **GHEENT QUINQUENNIAL EXHIBITION.**—This Exhibition, which opens on 16th inst. and closes on the 23rd inst., is expected to be both large and varied, but there does not appear to be anything like the "home interest" manifested in it that has been apparent on some previous occasions. We understand that the arrangements have been completed, and that some very fine exhibits are forthcoming. Orchids will form a special feature, and new plants will be well represented.

— **WEATHER AT LIVERPOOL.**—We have had another glorious week of sunshine and fine weather, but still no rain. The promise for fruit is wonderfully fine—Pears, Cherries, Plums, and Damsons being in full blossom, whilst the Apple trees are just covered with their pink buds, at the point of bursting. Although warm during the day, we have had rather severe frosts, with N.E. and N.W. winds, at night, but as yet I cannot detect any damage done to the blossom. Warm showers would work wonders, more especially on the small seeds.—R. P. R.

— **TRENTHAM AND HANFORD HORTICULTURAL SOCIETY.**—The sixth annual Exhibition of the above Society will be held, by the kind permission of the Duke of Sutherland, in Trentham Park, on Thursday, July 20th. A comprehensive schedule has just been issued, and this indicates that the Exhibition will be of an exceptionally interesting character. Some very liberal prizes are offered, those in one class, for groups, amounting to £72 10s. This is as large a sum probably as has ever been offered in a similar competition at any show, and should produce a keen competition. The Duchess of Sutherland, who takes a warm interest in the Show, offers £5 for flower prizes in the cottagers' division. The prizes in this department of the Exhibition are liberal throughout, and should attract large entries. In the competition for the best cultivated cottage garden a new departure has been taken. Instead of offering one set of prizes for the whole district, the Committee has divided the district into three, and prizes amounting to £3 8s. 6d. have been allotted to each. Entries close on Thursday, July 13th. Mr. John Taylor is the Hon. Secretary, and to his exertions much of the success of this Society is due.

— **WISTARIA CHINENSIS.**—"G. F., Salisbury," writes:—"This beautiful climber is now opening its long clusters of bloom freely on my cottage. It is a month earlier than last season, when it was cut off by frost on the 7th of May."

— **CAPE FRUIT.**—The Cape Fruit Syndicate have forwarded by the Royal Mail steamer "Norham Castle," which arrived in England last week, some boxes of Grapes addressed to the Prince of Wales and to Mr. Gladstone. This fruit has been sent as a gift from Sir Henry Loch, Governor of the Cape Colony. It would be interesting to know in what condition the Grapes arrived.

— **SUNDERLAND GARDENERS' SOCIETY.**—The fifty-second general meeting of the Society was held recently, the Chairman (Mr. Bolam) presiding. The Treasurer's report was read and adopted. Mr. Hall read an interesting paper on the culture of double Violets in frames and pots. A discussion followed, in which several members took part. A hearty vote of thanks was given Mr. Hall for his instructive and interesting paper.

— **ROYAL HORTICULTURAL SOCIETY OF IRELAND.**—It is stated that the following list of Exhibitions will be held under the auspices of this Society during the current year:—Spring Show, Royal University Buildings, Earlsfort Terrace, Thursday, April 20th; Summer Show, Lord Iveagh's Grounds, Thursday, July 6th; Autumn Show, Lord Iveagh's Grounds, Friday, August 25th; Winter Show, Royal Dublin Society's Buildings, Ball's Bridge, Thursday and Friday, November 16th and 17th.

— **ROYAL METEOROLOGICAL SOCIETY.**—At the ordinary meeting of the Society, to be held at 25, Great George Street, Westminster, on Wednesday, the 19th instant, at 7 P.M., the following papers will be read:—"The Direction of the Wind over the British Isles, 1876-80," by F. Campbell Bayard, LL.M., F.R.Met.Soc. "Notes on Photographs of Lightning taken at Sydney Observatory, December 7th, 1892," by H. C. Russell, B.A., F.R.S. "Notes on Lightning Discharges in the Neighbourhood of Bristol, 1892," by Ernest H. Cook, D.Sc. "Constructive Errors in some Hygrometers," by W. W. Midgley, F.R.Met.Soc. The above papers will be illustrated by lantern slides.

— **TESTIMONIAL TO MR. J. R. S. CLIFFORD.**—We are glad to learn that our entomological, and what we may also term our historical correspondent, Mr. J. R. S. Clifford, the author of "Gravesend and its Neighbourhood," "Homes and Home Life in Bible Lands," &c., &c., has been presented with a testimonial in recognition of the various efforts he has made for the intellectual advancement of Gravesend during many years' residence, and also of his general literary labours for the past twenty-five years, which have been largely of a philanthropic nature. The list of subscribers was headed by the Earl of Darnley, and a sum of £50 was speedily contributed towards the object in view. We congratulate our excellent coadjutor on this mark of esteem conferred on him by his friends and neighbours.

— **SPRING FLOWERS AT HAMPTON COURT.**—Although the Tulips planted amidst the Polyanthus here are, because of the recent sharp frosts and continuous dry weather, hardly so fine as usual, yet where the Polyanthus grounds are white or yellow-flowered, and Tulips of dark hues, the effects are very charming. How well they do Polyanthus at this favourite resort the thousands of plants put out into the beds show. There must be at least 5000 transplanted, mostly large clumps, and blooming profusely. The soil here, because so often worked and prepared for summer flowers, is perhaps lighter than is desirable for plants that have a preference for firm deep ground, but there is plenty of water at hand. From the present time till the end of the month the Hampton Court spring flowers should be very attractive.—D.

— **THE SPRING OF 1893.**—Mr. R. Maher, Yattendon Court, Newbury, writes:—"The splendid spell of bright sunshine, and perhaps the finest month of March on record, has shown some features of gardening interest worth recording. It has struck me that most of the early flowering hardy shrubs, such as *Andromeda floribunda*, *Laurustinus*, *Daphne laureola*, *Prunus californica*, *Ribes sanguinea*, and *Berberis aquifolium*, have never to my memory been so fine. The bloom of Plums, Cherries, and Pears are also a splendid sight at this time, and the promise is certainly very bright. On one occasion we had 12° of frost in March, but everything being so dry nothing seemed to suffer. All that seems wanting at present are showers to make a fine fruitful season. We had but very little rain during the month of March, and so far we have not had an April shower."

— **TORQUAY DISTRICT GARDENERS' ASSOCIATION.**—The first annual meeting of this Association was held on March 28th. The Secretary reported a membership of 120, several new names being promised for the ensuing session. The financial statement shows a balance of over £10 in hand. Several new features are contemplated, including the formation of a library, prizes for essays, &c. The summer outing will probably be to Taunton Flower Show on August 10th. W. Lavers, Esq., is President, and Mr. F. C. Smale Hon. Sec.

— **DEVON AND EXETER GARDENERS' ASSOCIATION.**—Members of the Devon and Exeter Gardeners' Association held a meeting at the Guildhall on the 5th inst., when Mr. Stoneman, Teacher of Botany at the Exeter Science Schools, read a paper, "The Coniferæ of Dropmore," on behalf of Mr. Cecil Bartlett of Dropmore. As illustrative of the paper read, a large number of branches were exhibited to show the characteristics of the trees referred to in the essay. A cordial vote of thanks was passed to Mr. Cecil Bartlett for the paper, to Mr. Stoneman for reading it, as also to Mr. Powell for presiding.

— **THE YOUNG GARDENERS OF FALKIRK.**—"A. G." writes:—"It may be interesting to some of your readers to know that the young gardeners of Falkirk and district formed themselves into an association for the purpose of petitioning their employers for a half-holiday on the Saturday afternoon. Most of the gentlemen conceded the holiday, but some have not as yet sent any reply to the circular that was sent to them on the subject. It is now proposed to form a Gardeners' Mutual Improvement Society in the district." [A head gardener to whom we mentioned the action and proposals above referred to replied:—"I think it is time an improvement society was established at Falkirk, and I hope my assistants have more respect for me than to run off enjoying themselves and leave me to do the necessary Saturday afternoon's work."]

— **THE WEATHER AT SWANMORE.**—The heat during the day has gradually increased through the present week. On the 7th inst. 76° were registered in the shade, or 7° in excess of last year, and 24° in excess of the temperature on the same day in 1891. The wealth of fruit blossom is as yet apparently unharmed; the petals from the Plum trees are whitening the ground. Pears and Cherries are fully expanded. The first Apple—Irish Peach—has opened its blossoms, followed by Lord Grosvenor. As yet we have not experienced frost, nor has any rain fallen since March 3rd. In strong land farming operations are much hindered owing to the want of moisture, and unless rain comes soon the hay crop will be light. Last year we had only 0.03 inch of rain from March 15th to April 13th, a long spell of drought.—E. M.

— **FRUIT FROM AUSTRALIA.**—A consignment of fruit from Victoria was opened on Tuesday morning in the Potato Market, Covent Garden, and was found to consist of Plums, Grapes, Pears, Tomatoes, and Apples. The Apples, magnificent in size, form, and colour, had travelled splendidly, and found a ready sale at a good price. The softer fruits had not fared so well, many of the Pears having lost their firmness, while few of the Plums had retained their freshness. Some of the Grapes were fresh with the bloom on them, but some of the contents of the boxes were quite soft and discoloured. The Tomatoes were pronounced to be first-rate in quality by a well-known authority in Covent Garden Market, and of these about a third were sound and fresh. The fruit left Melbourne on the 25th of February, having been stored in the cooling chambers of the ss. "Britannia" on the previous day.

— **THE WEATHER LAST MONTH.**—March was remarkable for the small quantity of rain during the month, the last fourteen days being quite dry; also for the large amount of sunshine, the seven consecutive days (19th to 25th) being quite clear, and not a cloud seen during the whole time. We had a little snow on 16th and 17th. The wind was in a westerly direction twenty-two days, but was only rough on one day, the 1st. The total rainfall was 0.24 inch, which fell on seven days, and is 1.21 inch below the average for the month, the greatest daily fall being 0.08 inch on the 1st. The barometer was highest (30.48) at 9 A.M. on 25th, lowest (29.42) at noon on 1st. Temperature varied much; highest in the shade was 67° on 30th, lowest 20° on 19th; lowest on grass, 13° on 19th and 29th; mean daily maximum, 57.96°; mean daily minimum, 30.19°; mean temperature of the month, 45.19°. Mean relative humidity (saturation = 100) taken at 9 A.M. was 76.29. The garden spring ran 24 gallons per minute on the 31st. The frost has been very severe at times, but the fruit blossom in the open here is not enough advanced to be damaged, and the prospects for all kinds are very good.—W. H. DIVERS, *Ketton Hall Gardens, Stamford.*

— A CONTEST IN FLORAL ARRANGEMENTS AT CHICAGO.—One of Mr. Thorpe's latest plans for the horticultural department of the World's Fair is for a contest in floral arrangement during the month of August. Of course the difficulties in making the contest truly national in character will be numerous, but he believes they can all be overcome. The month of August has been selected mainly because at that time so many florists will be sure to visit the Fair, and can take part without making a special trip for the purpose. Mr. Thorpe believes that many of the eastern florists will be sufficiently interested to have their material sent on from the east for the purpose, but all can enter and use material obtained in Chicago or within easy reach. Certainly such an important department of the trade as the arrangement of flowers should not be entirely omitted from a display intended to represent the progress of floriculture, and such contests always prove great attractions to the people. Mr. Thorpe believes that the rules to govern such a contest should be largely devised by those who will probably take part.—(*American Florist*.)

— LATE QUEEN BROCCOLI.—This fine variety is certainly worthy of extended cultivation, for according to my experience it is one of the hardest of Broccoli; and, moreover, is ready for use at a time when small white heads are particularly acceptable—viz., from the middle of April till June. It is the only variety which has wintered well with us this season. During severe winters thousands of midseason Broccoli are killed, and under the circumstances it is well to consider if it is desirable to plant midseason varieties so largely as heretofore, seeing how very precarious a crop they have been during the last few years. No mistake can, however, be made by having good breadths of Late Queen, for should the following winter prove mild this variety will be invaluable when the bulk of others are over. If, on the other hand, a severe winter is experienced, Late Queen comes to the rescue again by reason of its thorough hardiness. This is well worth bearing in mind now that the time has arrived for sowing the main batches of vegetables for winter and spring supply. I find the last week in April is early enough to sow this variety. The plants resulting therefrom are then ready to plant between rows of Potatoes at a convenient time—viz., after the haulm have completed their growth.—H. DUNKIN.

— SEED POTATOES.—I have often had occasion to remark as to the exceeding baldness of sorts of Potatoes for seed purposes offered in some provincial districts. Still further, how much residents in such localities owe to those more enterprising traders who distribute their Potato lists broadcast, as it is only through such energy that many varieties of Potatoes would get heard of at all. I have been looking through the lists of seed Potatoes that are issued in a considerable outlying town, and also taken stock of what is offered in seed shops or other ways, and have been surprised at the very meagre fare. One Ashleaf does duty for Myatt's, and Veitch's Early Rose does also for Early Vermont. Then there is Beauty of Hebron and its late ally, White Elephant, also Magnum Bonum, Schoolmaster, Imperator, and sometimes The Bruce. This is a fair representation of the sorts of Potatoes open to the grower whether rich or poor to select from. It is all very well to aver, as some critics who are wondrously wise will, that we have far too many sorts of Potatoes; but who complains of too many? In such a case as this, where is the enterprise of the local trader who thus drones on from year to year and makes little or no addition to such a poor stock? What wonder if the local trade is in a muddled and meagre condition. But whilst having no sympathy with such traders one may reasonably have some with that portion of the public who may not purchase of sorts new varied and good they would desire to do, but under ordinary local conditions can only of sorts they do not want. Even when they meet, as sometimes they do, with a list of sorts that affords ample selection, their wants are so moderate that they hesitate to order, and hesitating are lost. Did but a few combine to order, or would but one local trader resolve to invest in the purchase of some of the finer varieties for sale, great good to the Potato seed trade might be effected.—A. D.

## REVIEWS OF BOOKS.

*The Garden Manual.* E. H. May, 171, Fleet Street.

WE can, with the utmost propriety, allude to the re-issue of this work, as it embodies the teaching of practical men who have contributed to the pages of this Journal and its predecessor, the *Cottage Gardener*. Some of the writers whose work is cherished have been called away, while others happily remain. The teaching in the Manual is the outcome of ripe experience, and covers a wide field of practice in the various departments of gardening. It may be said that practically all kinds

of fruits, flowers, vegetables, and herbs are included, and their cultivation described. This applies to those which are grown both under glass or in the open air; in fact, we may say the *Garden Manual* provides information for everybody who needs it on the management of gardens and the cultivation of crops, and it also tells the readers in advertisements where they may obtain what they require. The work consists of 256 pages of closely printed matter, and though nearly 50,000 copies have been sold Mr. May says he wishes to sell more because it is such a useful handbook for amateurs, and contains more information for 1s. 6d. (1s. 9d. post free) than is to be found in any work that has been issued from the gardening press.

*The Wild Rabbit.* By J. SIMPSON. William Blackwood & Sons, Edinburgh and London.

WE direct attention to this new book, not because it has any connection with gardening, but because it is written by a gardener whose duties, however, extend far beyond the garden walls. Mr. Simpson is a believer in rabbit warrens, and is convinced that with good management they may be made to pay. They used to pay very well in England, and it may be presumed that rabbit rearing pays elsewhere, or hundreds of tons of them would not be imported. The author points out why in one important respect rabbit warrens have failed—starved land—and his remarks on the value of gas lime and salt for pastures are worthy of attention.

The late Professor Lindley, the eminent plant physiologist, wrote that many years ago "the pastures of Cheshire, exhausted by continual removal of grass by the animals that grazed upon them, recover their fertility when dressed with bones." Now this exhaustion is exactly what takes place in rabbit warrens from which large numbers of rabbits are removed annually and no bones or other manure ever put back in return. The Cheshire dairymen were quite right in concluding, in their common-sense way, that in putting bones on their pastures they would be putting back what their cattle took out of them; but, as Dr. Lindley showed, it was the combination of phosphoric acid and lime in the bones, otherwise phosphate of lime, of which the bones of animals are mainly formed, that restored the fertility of the pastures. "Hence arose the manufacture of superphosphate of lime by Mr. Lawes, now so indispensable to cultivators."

What the rabbit-warren farmer needs to realise is that the flesh, bones, and blood of a rabbit consist of from 55 to 60 per cent. of phosphate of lime; that the pasture on which it feeds consists in large part of the same elements; that the rabbit gets its nourishment out of the grass that it eats; that the grass gets the phosphates out of the soil; and that when the soil becomes exhausted of these, both pasture and rabbits must of course perish. This is the secret of the whole matter.

Of course, it is not needful to supply bones direct to rabbit warrens in all circumstances. In very many cases warrens are laid out on old pasture, where the food exists if only it were unlocked. We have applied no bones or phosphates yet, but only gas lime and salt; but we had a thickly matted old pasture full of fibre, humus, rabbit droppings, &c., to begin with, and which will take a good deal of decomposing and converting into plant food. Much of the pasture near the wood, where most rabbits were, was also what would be called tainted or rabbit-sick. This of course indicated lime, and as gas lime is just as good for grass as fresh lime, if not better, it was used pretty freely on the worst spots—put on in November, the right time—followed by a sprinkling of salt in spring. The lime acts upon the droppings and humus of the turf, converting both into the food of plants, aided by the salt, and both are energetic purifiers of the ground even on a limestone soil, which ours is not. The effect was at once apparent, by the improvement in the pasture and the eagerness with which the dressed parts were attacked by the rabbits. Salt, as is well known, has a marked influence on the health of animals, and promotes fertility. So noticeable was this, that a large quantity of gas lime and salt was also applied to the old deer park with the same results, the deer patronising the dressed land the whole summer.

The prejudice against gas lime—a prejudice entertained even by some noted and professedly scientific agriculturists—arises from ignorance. Dr. Voelcker, chemist to the Royal Agricultural Society, has pronounced emphatically in its favour, and especially recommends it for permanent pasture deficient in lime. But more is to be said about it than this. Gas lime is supposed to be obnoxious to animals on account of its smell; but that is not the case with cattle, horses, or rabbits. Gas tar will stink rabbits out of their holes, and is used for that purpose; but gas lime they will burrow in, and will live and breed in a fresh heap of it, as they have done here. They simply revel in it, and are on to it as soon as it is spread. Horses I have seen rubbing their noses in it with apparent pleasure, and cattle have no objections whatever to its presence. It should be well pulverised with a mallet or spade, and spread evenly on the pasture, but should never be applied after the tender grass begins to grow in spring, as it burns it off. Salt should be given freely to almost all pastures, especially when far from the sea. "The effects of salt," says Dr. Lindley, "are not to force plants and give them a dark colour like ammonia, but to consolidate their tissues and render them crisp as well as succulent," and no doubt more nourishing.

A thing happened here during the past summer worth mentioning in connection with this subject. As in most places, the young pheasants here have suffered more or less from cramp, that disease never being quite absent at any time till this year, when the coops were put down in the warren on a spot recently limed and salted. Last year on the same ground, close by, where no salt or lime had ever been put, cramp was bad; this year it was wholly absent, and similar dressings will be given where the pheasants are to be in future. I merely offer this hint to those whom it may concern.

The above remarks are suggestive and generally useful in their tendency, while the main subject of the work is practically treated in detail by the author. The volume will sustain the fame of the publishers by its excellence in production.

## DEATH OF PROFESSOR DE CANDOLLE.

WE regret to have to announce the death of Professor De Candolle, which took place on Tuesday, the 4th inst., at Geneva.

Alphonse Louis Pierre Pyramus De Candolle was the son of the celebrated botanist, Augustin Pyramus De Candolle, originally Professor of Botany at Montpellier and subsequently at Geneva. His son, the

1866 he was President, and delivered an inaugural address, the subject of which he divided into—I. The Utility of Horticulture to Botany; II. The Utility of Botany to Horticulture; and III. The Beneficial Effects of the Close Relations of Botany and Horticulture. He was a member of the Royal Society, also a member and gold medalist of the Linnean Society of London, and a recipient of the honorary doctor's degree from the Universities of Oxford and Cambridge.

FIG. 57.—ALPHONSE DE CANDOLLE, D.C.L., F.M.R.S.

subject of the present sketch (fig. 57), and who succeeded him in the Botany Chair in the University of Geneva, was born at Paris, October 27th, 1806. After going through a course of study in science and literature he directed his attention to the law, of which faculty he was admitted a doctor in 1829. Eventually he devoted his attention exclusively to botany, and became assistant to his father and afterwards his successor. For eighteen years he was director of the Botanic Garden. He was elected a correspondent of the Institute of France in 1851, and the following year was decorated with the Legion of Honour. At the great Horticultural and Botanical Congress held in London in

In June, 1874, De Candolle was elected a Foreign Member of the Institute, taking the place of Agassiz at his death. Besides completing the "Prodromus," which his father left unfinished in 1841, he was the author of several separate works, of which the chief are "Introduction à l'Étude de la Botanique," in two vols.; "Géographie Botanique Raisonnée," two vols.; "Lois de la Nomenclature Botanique;" "Origine des Plantes Cultivées," and "Constitution dans le Règne Végétal de Groupes Physiologique, Applicable à la Géographie Botanique Ancienne et Moderne." He also edited the Memoires of his father, and in the course of his industrious life published, in addition to the works already

mentioned, a "Monograph on Campanula," "Further Remarks upon Nomenclature," "History of Sciences and Scientists during two Centuries," which has passed through more than one edition, and "Photography; or, the Art of Delineating Vegetable Forms Considered from Various Aspects;" besides contributing largely to the Transactions and Journals of learned societies. He was ably assisted by his son Casimir, and thus three generations have been engaged upon similar studies in systematic botany and the properties and natural affinities of plants.

#### THE VITALITY OF THE N.C.S.

"THE N.C.S. has enough vitality in it to weather the storm, but there must be a good man at the helm." If the writer of the above sentence could be named in this reference, even Mr. Richard Dean might admit his authority—that is, if he admits any authority in the Chrysanthemum world. We believe fully in the vitality of the N.C.S., but all the world knows that the Society has not been increasing in dignity of late, and a loss of dignity, if permitted on the part of any national society, means a loss of strength. Of that there can be no doubt whatever. A flash and dash policy never lasts long, and not until small parochial methods are departed from can any society become truly great and command universal respect. A meeting will have been held before these lines are made public that will, it is hoped, place the National Chrysanthemum Society on a strong basis, and enhance its influence and prosperity.

#### NEW AMERICAN CHRYSANTHEMUMS.

MR. T. H. SPAULDING of transatlantic Chrysanthemum repute has recently published a somewhat lengthy list of novelties, comprising nearly all the new seedlings distributed by the leading American raisers, besides some introduced into that country direct from Japan. Last year's English and French varieties are also included, but omitting these we find a total of 142 new Chrysanthemums offered for the first time as new American sorts. The prices vary from 2s. to 6s. apiece for single plants, and we may well exclaim Verily our American cousins have caught the "Mum" fever!—P.

#### EARLY FLOWERING CHRYSANTHEMUMS.

Two years ago M. Simon Delaux announced the distribution of a large collection of dwarf early-flowered varieties, numbering in all 125 sorts, mainly of the Japanese section. Last year a further addition was made by him, but they do not appear to have justified the eulogiums which were pronounced upon them. This year M. Delaux promises to send us a fresh instalment, comprising fifty varieties, and another of his fellow countrymen has also entered the field with a list of twelve. The lovers of outdoor Chrysanthemums will have ample opportunities for the weeding-out process so long necessary with the older November flowering kinds from the other side of the Channel.—P.

#### UGLY CHRYSANTHEMUM NAMES.

THERE will, as usual, be a very large number of new Chrysanthemums sent out this spring by foreign growers, but the total imported into England will probably be less than in the past, for our introducers are beginning to get weary of the task, now that such a large proportion of sterling novelties reach us from America and from our own growers. Illustrative of my heading I select the following from the French catalogues:—Duminy Haré d'Olphove, Messidorine Vauvel, Billecart Charles, Sr. de Jules Pourbaix, René Deutz, Krug Paul, Paul Valade, Le Vidame de Moirax, Léon Faulguier, Vaucanson, Altair, Bailly de Sufren, Fuset Aublet, Chanoine Eysséris, M. Hovyn de Tranchère. The list might be lengthened, but the instances quoted are sufficient for the purpose of showing how easily Chrysanthemum nomenclature may become confused.—C. H. P.

#### HAIRY CHRYSANTHEMUMS.

ADVERTING to a short article which appeared in the *Journal of Horticulture* a few weeks ago, it may be of interest to record that the new American and Continental lists of seedling Chrysanthemums for 1893 contain between sixty and seventy varieties of distinctly hairy character, without counting those which possess this peculiarity in a slight degree. Among the French raisers the names of M. de Reydeliet, M. Simon Delaux, M. Crozy, M. Louis Lacroix, and M. Sautel are chiefly conspicuous for offering novelties in this section, while the varieties sent out by American houses are contributed mainly by Mr. Spaulding, Messrs. Pitcher & Manda, and Messrs. Nathan Smith and Son.

A new departure in the hairy section is about to be made, for I learn that one grower on the Continent promises us several, which, instead of merely having short, glandular, hairy growths on the backs of the petals, are noteworthy as having hairy petals the whole length, similar,

perhaps, to what we once knew as thread-petalled varieties, but much finer. Mrs. Alpheus Hardy and Louis Boehmer seem to have played an important part in the operations of the raisers, although introductions direct from Japan are announced. We may, therefore, look forward to the next Chrysanthemum season with considerable interest, and those who favour the most modern section of the popular autumn flower will, no doubt, keep a keen look-out for the most promising varieties of these new but doubtful beauties.

English nurserymen have at present but two terms to describe them—viz., hairy varieties or hirsute varieties; but our French friends seem not to be limited in their vocabulary. I find in the French catalogues the following expressions plentifully used, which seem worthy of repetition for the benefit of those desirous of extending their knowledge of that language, Chrysanthèmes à barbe, à plume d'autruche, à poils, barbus, ciliés, duveteux, velus, chevelus, plumeux, and poilus.—C. H. P.

#### JUDGING CUT BLOOMS.

I AGREE with Mr. Lambert (page 278) that an exhibitor gains points when he can stage difficult varieties like Mrs. A. Hardy, Golden Dragon, and many others, but this phase has nothing to do with the principle of judging that I object to, it is quite outside of it. Surely it should make no difference to a judge whether a stand is placed near another or not in determining the merits of any particular collection, or even individual blooms. If a judge knows the quality of any individual variety it matters little to him where it is placed. A practical man does not require other blooms to guide his mind. Surely a judge can discriminate between a 4-point flower and another 4½ points without fetching the former for comparison; if he cannot he is not competent to award prizes.

Has Mr. Lambert ever awarded the premier prize to a bloom of Refulgens where Lord Alcester in prime condition was competing? If he has his experience differs from that of others. If Refulgens cannot beat the variety quoted in the contest for the premier bloom why should it be placed ahead of it in a collection simply because it happens to be of another colour?

Dealing with the matter of 6-point blooms, Mr. Lambert (page 278) does not put the matter quite fair regarding what he previously said on page 240 when speaking of the premier bloom selection. He there infers that many blooms in a show had gained six points, whereas in his last communication he shifts this inference by saying only one in five, which renders the selection of the premier bloom an easy matter on my method of judging.—SADOC.

#### ROYAL HORTICULTURAL SOCIETY.

APRIL 11TH.

THERE was a very attractive display in the Drill Hall on the present occasion, and the exhibits were thoroughly well varied in character—hardy flowers, indoor plants, and Orchids all contributing their quota, while fruit and vegetables were also represented.

FRUIT COMMITTEE.—Present: Philip Crowley, Esq. (in the chair), with Dr. Hogg, Messrs. G. Bunyard, J. Cheal, G. Forbes, G. Woodward, J. Smith, H. Balderson, G. Wythes, W. Bates, G. Sage, F. Q. Lane, A. J. Laing, A. Dean, Harrison Weir, and J. Wright.

Several varieties of Apples were placed on the table by Mr. Barron. They were grown in pots under glass last year at Chiswick, and exhibited to show that the fruits have kept better than those of the same varieties grown in the open. The specimens were very good indeed, pale, with a wax-like transparency, much resembling Tasmanian fruits.

Mr. G. Woodward, Barham Court, Maidstone, sent a dish of Apples named Roy d'Angleterre; good-sized symmetrical fruits, green, with a russet apex, firm, and of fair quality, but probably past their best condition; and the variety would be better represented earlier in the season.

A month ago the beautiful orange-yellow Apple *Jacquin* was exhibited by Mr. Rivers, and the fruits were preserved to test their keeping properties. They were again examined by the Committee, and were quite sound. This is one of the most distinct Apples that has been seen for a long time. The fruits are medium-sized, conical, clear uniform orange-yellow, and the flesh tender, juicy, and agreeably flavoured. The specimens were grown in the open air. A first-class certificate was unanimously awarded, and *Jacquin* will probably become a favourite Apple for dessert purposes.

Mr. F. Q. Lane sent a dish of Lane's Prince Albert Apples, splendid fruits, as firm as when gathered, and a vote of thanks was accorded.

Royal Sovereign Strawberry plants in pots were exhibited by Mr. T. Laxton, Bedford. This variety was certificated last year; the fruits were very large, and of excellent quality (cultural commendation).

Mr. Wythes, Syon House Gardens, sent a box of Strawberries, a seedling from Keens' Seedling, excellent fruits of good colour; good Black Hamburgh Grapes, and St. John's Figs, also a collection of vegetables including Sharpe's Victor Potatoes, Dwarf Kidney Beans, Asparagus, Seakale, and other kinds in season. A silver Banksian medal was unanimously recommended.

The first Vegetable Marrows of the season were sent by Mr. W. C. Leach from Albury Park. The name given was Sutton's Vegetable Marrow, but there were two varieties on the dish. The fruits were 6 inches long, and of good table quality, but no award was made.

Very fine samples of *Veitch's Golden Queen Cabbage Lettuce* were exhibited by Mr. T. W. Bond, gardener to C. Ingram, Esq., Elstead House, Godalming. They were of full size, firm, tender, and pleasing in colour. The opinion was general that no Lettuces, from France or elsewhere, sold in Covent Garden at the present time equalled these specimens, and a first-class certificate was awarded for Golden Queen as a forcing variety. The seeds were sown on January 2nd, and the plants were admirably grown by Mr. Bond.

Fifteen dishes of Apples were sent for the last meeting by Mr. W. Divers, The Gardens, Wierton House, Maidstone, but did not arrive in time, and had suffered by the delay (vote of thanks).

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair), Messrs. H. B. May, H. Herbst, R. Dean, G. Stevens, F. Bause, J. Jennings, R. B. Lowe, W. C. Leach, C. Jeffries, W. Bain, G. Gordon, C. E. Shea, H. H. D'Ombraim, J. D. Pawle, C. Noble, T. Baines, J. Fraser, H. Turner, E. Mawley, G. Paul, and C. E. Pearson.

J. C. Tasker, Esq., Brentwood (gardener, Mr. Perry), sent a group of Azaleas, Spiræas, and Roses, the latter including the charming Teas Princess of Wales, The Bride, and Innocente Pirola, in admirable condition (silver Flora medal). Messrs. H. Lane & Sons, Berkhamsted, contributed baskets of the Polyantha Roses Gloire des Polyanthas, Perle d'Or, and Anna Maria de Montravel, also of the magnificent hardy Azalea Anthony Koster, with its huge trusses of yellow, orange suffused flowers (silver Banksian medal). Messrs. E. D. Shuttleworth & Co. sent a group of miscellaneous plants, chiefly Cycads, all healthy and clean, also a bright collection of hardy flowers (bronze Banksian medal). Messrs. J. Laing & Sons contributed a mixed group of flowering and foliage plants, in which tree Pæonies, Clivias, Azaleas, and Lilacs showed up prominently. The group was very tastefully arranged (silver-gilt Banksian medal). Mr. T. S. Ware had a somewhat extensive and well varied collection of Daffodils, also a few Irises, including the charming Saari nazarensis and Helenæ (silver-gilt Banksian medal). Messrs. B. S. Williams & Son had a group of flowering plants which comprised Clivias, Amaryllis, and a fine plant of Rhododendron McNabbiana, which last year was at its best at the end of May (silver Flora medal). Messrs. Hugh Low & Co. sent a large and diversified collection of stove and greenhouse plants, chiefly hardwooded, all healthy and beautifully bloomed. Their exhibits of this class are so strikingly attractive that the plants can hardly fail to be popularised (silver-gilt Flora medal). Messrs. Veitch & Sons were represented by a small collection of seedling Daffodils, and also by several baskets of shrubs. Cydonia Maulei, C. japonica rosca, C. j. atropurpurea, C. j. alba, C. j. Moerlezi, Andromeda speciosa cassinefolia, Cerasus Watereri (very beautiful), and Olearia Gunni (silver Banksian medal).

The Rev. G. H. Engleheart, Andover, sent several seedling Daffodils, such as a cross between Horsefieldi and poeticus, this having resulted merely in the shortening of the crown. The first prize for six varieties of these flowers went to the Rev. G. P. Haydon, Doncaster, and the second to J. W. Melles, Esq., Chingford. The Rev. S. Eugene Bourne was first with nine, and A. Kingsmill, Esq., second. Mr. Bourne also won with a collection of Daffodils, Mr. Kingsmill second, Mr. Haydon third, and Mr. Miller fourth. Mr. J. W. Wilson exhibited a small collection of Daffodils, as did the Rev. N. J. Miller. Two beautiful boxes of Roses were sent by Mr. Frank Cant, and they constituted a really remarkable exhibit for the time of year, the blooms being delightfully fresh and well coloured. Mrs. John Laing, The Bride, Vicomtesse Folkestone, Ethel Brownlow (superb), and Suzanne Marie Rodocanachi were exceptionally good (silver Flora medal). Three beautiful baskets of alpine and other plants came from the Guildford Hardy Plant Nursery. Amongst them were the rare and troublesome Eritrichium nanum, Myosotis Rechsteineri, Draba Dedeana, Saxifraga Stanfieldi, S. tenella, and Antennaria dioica (silver Flora medal).

Messrs. Cannell & Sons sent some rich and fragrant masses of Wall-flowers, such as Cannell's Tall Yellow, Blood Red, Harbinger, Graham's Yellow, Double German, and Cannell's Dark Maroon; also a basket of Primrose Harbinger (vote of thanks). Messrs. Cutbush & Son had a miscellaneous group of indoor plants, in which well flowered Ericas, Callas, Clanthus, and Pæonies were prominent (silver Flora medal). Messrs. J. Peed & Son had a mixed group of flowering and foliage plants, composed as usual of healthy and well grown material (bronze Banksian medal). Martin R. Smith, Esq. (gardener, Mr. Blek), sent several seedling Malmaison Carnations, such as Sir Evelyn Wood, Lord Wolseley, and Princess May. The latter is referred to below. Mr. Edward Morse sent Convallaria majalis grandiflora, Fortin's variety (vote of thanks); and Miss Mellish, Hodsock Priory, some fine seedling Daffodils. Mr. W. C. Leach sent Philadelphus grandiflorus and Salvia gesneræflora. G. F. Wilson, Esq., sent several varieties of Gentiana acuta, marking many divergencies of colour. J. T. Bennett-Poë, Esq., received a vote of thanks for Richardia aurata—Deleuil (R. albo-maculata × R. hastata) with pale primrose flowers and marbled foliage.

Messrs. P. Barr & Son were represented by one of their characteristic collections of Daffodils, comprising an enormous amount of material, and many interesting forms (silver-gilt Banksian medal). Messrs. Paul and Son, Cheshunt, had a charming group of hardy flowers and shrubs, in which Cytisus præcox and C. scoparia Andreana were conspicuous as weeping standards (silver Flora medal). Mr. G. May, Teldington, had a large group of a fine new tree Carnation named Uriah Pike, flowers with full rich Clove fragrance (silver Banksian medal).

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair); Messrs. J. O'Brien, De B. Crawshaw, H. M. Pollett, E. Hill, Hugh Low,

Jas. Douglas, R. B. White, C. J. Lucas, J. T. Gabriel, H. Williams, E. Handley, S. Courtauld, H. Ballantine, and Dr. Masters.

The labours of the Orchid Committee were not so heavy as usual. Messrs. Hugh Low & Co. sent a very bright little group containing no novelties but brilliant with bloom (silver Banksian medal). Messrs. Veitch & Son sent Dendrobium Niobe (see below), Cymbidium × eburneo Lowianum, and Cypripedium × Clymene. The Duke of Northumberland (gardener, Mr. Wythes) sent a plant of Miltonia stellata and Cyrtopodium punctatum splendens (see below). The Rev. E. Handley sent Odontoglossum Andersonianum and Cattleya Laurenciana Omala. Messrs. Sander & Co. contributed a small but interesting group of Orchids, amongst which were Dendrobium Schröleræ, Odontoglossum Kranzlini, Cattleya Schröleræ, and a fine variety of Odontoglossum Pescatorei. The Right Hon. J. Chamberlain (grower, Mr. Burberry) sent Cattleya guatemalensis (see awards), Dendrobium Nestor, and Cattleya Trianae pallida. Messrs. B. S. Williams & Son had a large and brilliant group full of bloom (silver Flora medal). Messrs. W. L. Lewis & Co. also had a charming group not containing any special forms, but very attractive for all that (silver Banksian medal).

#### CERTIFICATES AND AWARDS.

*Carnation Princess May* (Martin R. Smith, Esq.).—A fine seedling Malmaison variety with "Warocqué" blood. It is dwarf, with very large flowers of a rich crimson, and very sweet (award of merit).

*Eucharis Lowi* (Hugh Low & Co.).—A beautiful variety, pure white, with greenish-yellow stamens, the segments somewhat incurved, giving it a distinct appearance (award of merit).

*Bougainvillea spectabilis* (Captain Oldfield).—Remarkable for the rich colouring of the bracts, which were exceptionally bright, and would have looked still finer under sunlight. They were of a brilliant magenta (first-class certificate).

*Carnation Uriah Pike* (G. May).—A tree variety with the true Clove perfume, colour rich purplish crimson. The plant is of good habit, and the bloom does not split its calyx (award of merit).

*Pyrus cardinalia* (A. Waterer).—Apparently a large and fine variety of japonica. The blooms are 2½ to 3 inches across, rich scarlet and densely clothe the stem (award of merit).

*Azalea Anthony Koster* (H. Lane & Son).—A magnificent variety of the hardy section with huge trusses of bloom. The individual flowers are large and the plants smothered in flowers. Colour clear yellow suffused with orange (first-class certificate).

*Iris Saari nazarensis* (T. S. Ware).—A beautiful variety growing about 9 inches high, the standards transparent white, the falls white dotted thickly with brown, and with a large purplish patch in the centre (award of merit).

*Sarracenia Mandaiana* (Pitcher & Manda).—A natural hybrid between flava rubra and Drummondii with magnificent green pitchers (first-class certificate).

*Canna Progression* (Paul & Son, Cheshunt).—A beautiful variety with large yellow flowers, thickly dotted with brownish red (award of merit).

*Dendrobium Niobe* (J. Veitch & Sons).—A cross between D. nobile (pollen parent) and D. tortile. It is of vigorous growth and free blooming. The flowers are much larger than those of nobile, lip creamy white tipped with magenta, throat purplish magenta, sepals and petals brilliant rosy mauve (award of merit).

*Cyrtopodium punctatum splendens* (the Duke of Northumberland).—Three splendid pieces, all profusely flowered. The colour is a combination of brown and yellow, the lip being yellow with brown blotches, the upturned wings brown, the petals clear yellow, and the sepals greenish yellow blotched with brown (award of merit).

*Cattleya guatemalensis* (Right Hon. J. Chamberlain).—A small flowered sort of peculiar colouring, the sepals being buff with a tinge of rose, the petals suffused with rose, and the narrow lip rich rosy cerise. It is an old plant (award of merit).

*Odontoglossum hybrid (?) Crawshaw's variety* (De B. Crawshaw, Esq.).—The nomenclature of this was not decided. It has marked crispum characters, and is white, heavily blotched with brown; a beautiful form (award of merit).

#### THE LECTURE.

It was announced in the programme that a lecture on "Orchid Life in New Guiana," by Mr. Everard F. im Thurn would be delivered at the afternoon meeting held under the auspices of the Royal Horticultural Society; but a letter was read by the Rev. W. Wilks indicating that Mr. im Thurn was on his way to Barbadoes, and had not been able to prepare the essay previous to embarking. He promised, however, that the paper should be forthcoming, but at the time of the meeting it had not come to hand. As a substitute a paper on the "Antiquity of the Citron in Egypt," by Dr. Bonavia, was read by the Secretary, and this proved of an interesting character.

Dr. Bonavia, on the authority of other authors, in his communication stated that the Citron was cultivated in Upper Egypt in the fourth century A.D., and further remarked that two centuries before that date ancient writers referred to the fruit being sold to poor people. He thought, too, that the Citron was known long before that period, inasmuch as it was figured on a tomb in the temple at Karnak fifteen centuries B.C. As further evidence of its antiquity he had seen a copy of a drawing in which the "finer Citron" is figured. As to the probable source from which the Citron originated, Dr. Bonavia said it had probably been brought by traders into Egypt, but he had come to the conclusion that all varieties originated in Southern China. Ancient Greek, Roman, and Arab writers had, he said, referred to the medicinal

properties of the Citron, and in one instance he could corroborate the views set forth in this respect.

Phillip Crowley, Esq., who occupied the chair, and whom the Rev. W. Wilks described as the best Citron grower in England, briefly alluded to his method of culture, and remarked that he had grown Citrons successfully for several years. The fruit made excellent preserves, far superior to the ordinary marmalade, and he thought that the Citron should be more extensively grown under glass in this country.

Sir John Llewelyn, Bart., alluded historically to the trees in the Margam orangery, in Glamorganshire, and made a suggestion to the effect that although ancient figures of the Citron were found in Egypt it did not necessarily follow that the trees were cultivated at those periods in that country. Fruits, he said, may have been brought into the country from other lands and drawings made of them.

### PRIMULA CALYCINA.

THIS *Primula* (fig 58) has long been known in gardens, where it is often confounded with *P. Wulfeniana*, a totally different plant, and from which it is easily distinguished, even without the aid of flowers, by its longer and very irregularly margined leaves. It grows readily enough on the rockery in almost any position, but unless in exposed situations is rather a shy flowerer, and some can only manage to flower it by giving it a good roasting during the summer months, meanwhile supplying water very sparingly. It seems to prefer being wedged between hard pieces of granite in a rich stiffish soil.

It forms rosettes of long ovate-lanceolate leaves, of a half-weathered green colour, perfectly glabrous and shining, with a curiously wavy margin. The flowers are large, of a beautiful clear lilac, generally three or four together on short stalks, at the base of which are long linear bracts. Calyx about an inch long, with narrow bluntish sepals. It is a native of the southern Alps, and flowers generally in May and June.

## SPRING FLOWER SHOWS.

### BIRMINGHAM.—APRIL 5TH AND 6TH.

THE thirteenth annual Exhibition was held in the Town Hall on the 5th and 6th inst., and the Judges, exhibitors, and visitors pronounced it to be the best spring Show yet held at Birmingham. It was generally thought, owing to the hot weather experienced for several days, that there would be but a moderate display of Hyacinths and Tulips, but all fears on this score were groundless, and each of the seven classes for these plants were well filled.

In the class for eighteen Hyacinths Mr. J. Palmer, gardener to Wm. Bown, Esq., was first, and among these were fine examples of King of the Blues, Czar Peter, and Lord Macaulay. Mr. W. H. Dyer, gardener to Mrs. Marigold, was second, showing very fine specimens of King of the Blues and Koh-i-noor. There were five entries in this class. For twelve Hyacinths there were six competitors. First, Mr. John Priest, gardener to A. W. Hulse, Esq., with Von Schiller, Blondin, King of the Blues, Grande Maître, Mont Blanc, and Koh-i-noor. Second, Mr. T. Beasley, gardener to N. Thwaites, Esq. For six Hyacinths Mr. Hulse was again first and Mrs. Marigold second; there were six exhibitors in this class.

The Tulips throughout were well grown. For six pots of single Tulips, five roots in a pot, Mrs. Marigold was first, the White Joost Van Vondel, Ophir d'Or, Proserpine, Vermillion Brilliant, Joost Van Vondel, and Keizers Kroon, all being very fine. Second, N. Thwaites, Esq.

Lily of the Valley in moderate sized pots were plentiful and good, and there were large handsome specimens of *Dielytras*, *Spiræas*, *Deutzias*, and *Azalea mollis*. The specimens of *Azalea indica* were unusually fine and formed a marked feature. For six specimens Mr. P. McGregor, gardener to Mrs. Grice, Harborne, was first; W. Bown, Esq., second; and Mr. Cryer, gardener to J. A. Kenrick, Esq., Berrow Court, third. For three specimen Azaleas Mr. L. Fewkes, gardener to T. Clayton, Esq., Castle Bromwich, was first; Mr. Brasiere, gardener to Sir Thomas Martineau, second; and W. Bown, Esq., third. For six stove and greenhouse plants in flower, Sir Thomas Martineau was first with some fine specimens, including *Pimelea spectabilis* and a grand *Hydrangea Thomas Hogg* nearly 3 feet in diameter. Some remarkably fine pyramidal specimens of *Genista fragrans* were shown, ranging from 4 to 6 feet in height, and well flowered; J. B. Manley, Esq., took the first prize.

Prizes were offered for a group of Orchids, arranged with Ferns or foliage plants, in a space not exceeding 40 square feet, and two fine collections were staged. Mr. Burberry, Orchid grower to the Right Hon. Joseph Chamberlain, M.P., Highbury, staged a very fine group, which obtained the first prize. An artificial tree was erected, and the Orchids so arranged as to show the manner in which some of the species grow in other countries. Amongst the Orchids in this group were a very fine plant of *Lælia anceps grandiflora* (Highbury variety); *L. anceps Williamsi*, *Lycaste Skinneri alba*, *Cattleya Mendeli*, *C. Schrederi*, *C. Trianae* (Archduchess variety), and *C. Trianae pallida*; *Dendrobium luteolum*, *D. nobile Cooksoni*, and *D. nobile giganteum*; *D. suavisimum*, very rich in colour; and *D. lituiflorum*, a lovely species; *Angraecum Sanderianum*, the curious *Restrepia antennifera*, *Chysis*

*bractescens*, and the lovely *Lælia flava*. Second, W. Bown, Esq., with a very pretty group, and in it were some choice kinds.

For six Orchids, *bonâ fide* specimens, Mr. Bown secured first prize, showing fine plants of *Cypripedium villosum aureum*, with forty open blooms; a grand variety of *Cymbidium Lowianum*, with eighty open flowers; *Lycaste Skinneri*, *Dendrobium Wardianum*, *Cattleya Lawrenceana*, very rich in colour, and *Dendrobium Ainsworthi*, profusely flowered. The Right Hon. Joseph Chamberlain was second. For three Orchids the Right Hon. Joseph Chamberlain was first with a very large pan of *Cœlogyne cristata*, *Dendrobium thyrsoflorum* in a small pot and with nine large racemes, and *Dendrobium Falconeri*. For a single specimen Orchid Mr. W. Bown was first with a superb plant of *Cymbidium eburneum*, with forty spikes of flowers. Second, the Right Hon. J. Chamberlain with a large *Sobralia macrantha*. Third, J. H. Kenneth, Esq., with a very fine *Dendrobium nobile*.

Some pretty groups of plants were staged in competition, J. N. Kenrick, Esq., being first, Mrs. Marigold second, and Sir Thomas Martineau third; and two extra prizes were also awarded. Messrs. Pope & Sons, nurserymen, &c., were first for a ballroom bouquet in the open class. Messrs. Thomson & Co., nursery and seedsmen, gave liberal special prizes for eighteen Hyacinths, and there were nine competitors. Mr. John Priest, gardener to A. W. Hulse, Esq., was first; N. Thwaites, Esq., second; Mrs. Marigold third, and Sir Thomas Martineau fourth. Messrs. Thomson & Co. also offered special prizes for twelve pots of Tulips, and the exhibits were of a very satisfactory character. First, Mrs. Marigold; second, N. Thwaites, Esq.; third, A. W. Hulse, Esq. Messrs. Thomson & Co. and Messrs. Sutton & Sons also gave special prizes for their strains of Cinerarias, and the latter firm for their superb strain of Cyclamen. Messrs. R. Smith & Co., Worcester, offered special prizes for twelve *Lilium Harrisii*; Messrs. Webb & Sons for Cinerarias; Messrs. Pope & Sons for specimens of *Hydrangea Thomas Hogg*; and Mr. R. Sydenham, Tenby Street, for twelve pots of Narcissus, Mr. A. W. Hulse being first, Mr. N. Thwaites second, and Mr. G. H. Kenrick third.

The honorary exhibits were numerous, sufficient to make a pretty exhibition by themselves. Messrs. Cutbush & Son, Highgate Nurseries, London, contributed a large group of new double Ghent Azaleas, *Azalea mollis*, new *Imantophyllums*, *Ericas*, and other greenhouse plants. Messrs. Ryder & Co., The Nurseries, Sale, Manchester, sent a large collection of *Primula Sieboldi*. Messrs. Peter Barr & Son, nursery and seedsmen, London, sent a good collection of leading Narcissi, amongst them J. B. M. Camm, Lady Grosvenor, Marchioness of Lorne, M. J. Berkeley, deep golden yellow and very fine; Queen of Spain, Barri conspicua, C. J. Backhouse, Mr. H. J. Elwes, and Minnie Hume, a sweet scented variety. Messrs. Dicksons (Limited), Chester, contributed a group of Narcissi of leading varieties and cut blooms of many interesting plants, such as *Epigæa repens*, *Anemone pulsatilla*, *Muscari botryoides pallida* and *alba*, *Fritillaria meleagris angustifolia*, &c. Messrs. R. Smith & Co., Worcester, staged a large group of Clematis, hardy Azaleas, *Rhododendrons*, Japanese Maples, and other plants.

Messrs. Hewitt & Co., The Nurseries, Solihull, had a tastefully arranged group of plants, including Narcissi, *Ericas*, *Azalea mollis*, the handsome hybrid Ghent Azalea *Daviesiana*, a pure white *Caladium*, and other plants, also some Narcissi and Mignonette in pots. Messrs. Thomson & Co., nurserymen and seedsmen, had a large and admirably arranged group, with a centre of Japanese Maples and *Lilium Harrisii*, and a pretty display of *Azalea mollis*, Lily of the Valley, Narcissi, Palms and various other plants. This firm also exhibited a large and very beautiful floral design, an Irish harp. Messrs. Pope & Sons, nurserymen and seedsmen, contributed eight arrangements of Narcissi, Ferns, and foliage as shower bouquets, one variety in each, and these were very handsome, and were in the centre of a group of plants.

Mr. Robert Sydenham, Tenby Street, staged some fine Hyacinths. There were new varieties amongst them, such as King of Yellows, a handsome variety; Etna, a deep rose, large handsome bells and fine spike, a fine semi-double variety; King of Blues, extra fine; Morena, similar in colour to Norma, but with a much finer spike, and is a great acquisition, but has a tendency to lose its brightness of colour somewhat early; Peter Barr, a lovely purple with white centre; Princess of Wales, a new rich rose-coloured variety and a fine spike. Koh-i-noor was shown very fine indeed, some with spikes nearly a foot in depth; Princess Amelia, resembling Grandeur à Merveille, and when seen fine is a decided acquisition; Duchess of Edinburgh, a pale pink, a very charming variety with a grand spike and well finished top; Cardinal Wiseman, another new variety, like *Fabiola* in colour, but with a bold fine spike, and is fine for exhibition. Pink Perfection is quite a distinct shade of colour, white with a rich lavender shaded pink base. Some fine pots of Tulips were staged with the Hyacinths, including some newer kinds; also some Narcissi, including Queen of Spain, a lovely variety.

### ROYAL CALEDONIAN.—APRIL 5TH AND 6TH.

NEVER since the time the leading Scottish Horticultural Society left the dingy Music Hall in George Street for the spacious, well lighted Waverley Market, has there been brighter weather for a spring Show than there was last week on the above occasion. One naturally expected that so fine a season would have brought out an Exhibition correspondingly exceptional. But there have been better shows held in worse seasons. To the nurserymen of the city who contributed freely much of the success of the Show was due.

Nothing in the building could compare with the charming group of

plants arranged by Messrs. T. Methven & Sons, Prince's Street, Edinburgh. The material was composed of ordinary spring decorative plants, with a few charming light blue Clematis, some *Acer Negundo* variegata and Japanese Maples intermixed. Messrs. Dicksons & Co., Waterloo Place, also contributed a table of fine-foliaged and flowering plants, as likewise did Messrs. Cunningham, Fraser, & Co., Queensferry Street. A bright group composed entirely of *Clivias* was contributed by Messrs. R. B. Laird & Sons, Frederick Street. Messrs. Sander, St. Albans, filled a large table with Orchids, these mostly of *Dendrobium Dalhousianum*, *Oncidium ampliatum majus*, and *Odontoglossums*. Mr. Thomson, Frederick Street, showed Ghent Azaleas; and Messrs. Laing & Mather, Kelso, blooms of *Souvenir de la Malmaison* and *Germania* Carnations.

The chief prizewinner was Mr. McIntyre, The Glen, Innerleithen, to whom several of the prizes for plants was awarded. Of these the premier honour for a table of plants, 20 feet by 5 feet, was the chief item. Some good Orchids, *Amaryllis*, and *Crotons* were included in this group. The second prize went to Mr. A. Crichton, Liberton; and the third to Mr. G. Wood, Oswald House, Edinburgh. Mr. McIntyre was also first for six Orchids, showing good examples of *Cymbidium Lowianum*, *C. eburneum*, a large mass of *Cœlogyne cristata*, a good *Cypripedium villosum*, *Dendrobium Wardianum*, and *Vanda suavis*. Mr. W. Sharp, Freeland, Perth, was a good second; and Mr. R. Grossart, Broughty Ferry, Dundee, third. For three Orchids, Mr. Curror, Eskbank, was first with good plants of *Dendrobium fimbriatum*, *Cœlogyne cristata*, and *Cymbidium Lowianum*. The prizes for one Orchid were awarded to Messrs. Chaolin, A. Patterson, and D. Wilson.

Azaleas were well represented. The best four Azaleas were staged by Mr. J. Bald, Canaan House, Edinburgh. Of foliage plants Mr. Plenderleith was first for four distinct species, a good *Croton* and a large *Asparagus plumosus* being noteworthy. In the class for four exotic Ferns Mr. Napier, gardener to P. Niel Fraser, Esq., Murrayfield, staged a quartet of fresh good-sized plants. Mr. J. Harvey, gardener to Colonel Trotter, Morton Hall, Liberton, was second. Mr. Napier also secured first places for Filmy Ferns and for three *Adiantums*. *Cyclamens* were good, though all the plants were small. Mr. T. Lunt, Dunblane, was the first for twelve; and Mr. A. Kirk for six plants.

Dutch bulbous plants were not so numerous as in some years, nor were they on the whole so good. For twelve Hyacinths Mr. H. Miller, Bothwell, was first with fairly good spikes, *Von Schiller*, *Moreens*, *Koh-i-Noor*, and *La Grandesse* being the best. Mr. D. McBean, Craigeads, Renfrew, was a good second. For eight varieties Mr. C. Carnegie, Gartshore, Kirkintilloch, occupied first place, Mr. J. Pearson, Beechwood, Corstorphine, being second. Tulips were bright but small in bloom. Mr. Pearson showed the best six 9-inch potfuls. Of *Narcissus* nothing special was shown. *Cinerarias* were exhibited in numbers, as likewise were *Deutzias*, *Spiræas*, *Mignonette*, and other seasonable plants.

Of cut flowers the most interesting were those made up into bouquets, buttonholes, and sprays for ladies' personal decoration. Mr. Johnston, Morningside, secured the first prize for a hand bouquet; Mr. J. Fraser, Canaan Park, a like award for a bride's bouquet. Mr. J. Napier, Musselburgh, for six buttonholes, was first; and for a "spray" Mr. Kinmont, Pitlochry, was first. Mr. McIntyre, The Glen, was first for twelve Orchid trusses, Mr. Grossart second, and Mr. Sharp third. Cut stove and greenhouse flowers were also attractive. Mr. Grossart staged the winning twelve, Mr. McIntyre being second, and Mr. Sharp third. Roses were not numerous, and many of the blooms were small. By far the best were those in the stand with which Mr. Parlane, Rosslyn, took first prize for twenty-four blooms. The twelve first prize buds of *Maréchal Niel* staged by Mr. T. Fender, Coltoquy, Crieff, were good. Mr. Pearson, Beechwood, was a close second.

Fruit was represented by a few dishes of Strawberries, four clusters of Lady Downe's Grape, and some Apples. However, the *Vicomtesse Héricart de Thury* Strawberries with which Mr. Smith, Oxenford, easily secured first prize, were of great excellence. Mr. Smith was also first for Grapes, Mr. Kidd, Carberry Tower, being second. Very few vegetables were shown.

Classes devoted to the trade were not largely filled. Messrs. R. B. Laird, the only exhibitors of Hyacinths, were first for twenty-four spikes, also for Tulips and for *Narcissus*. For four *Azalea indica* Messrs. Dicksons & Co. were first, and Messrs. Laird second, the same firms being the only exhibitors in several classes, and dividing the first and second prizes between them. Mr. J. Bryson, Heliosburgh, was the only exhibitor of cut Roses; and Messrs. Laird, in like manner, the only firm that staged cut *Camellias*.

#### BRIGHTON.—APRIL 11TH AND 12TH.

THE second annual Exhibition of spring foliage and flowering plants was held in the Corn Exchange on Tuesday and Wednesday, April 11th and 12th. The entries in the majority of the classes were numerous, and the competition keen. The exhibits, as compared with last year, showed an appreciable improvement both in the quality of the plants and in number of entries. The arrangements of the Show were excellent, and reflected much credit on the Committee and its able and energetic Secretary, Mr. Mark Longhurst. Messrs. Glen and Hudson were the Judges.

Class 1. for twelve Hyacinths in pots, not less than six varieties, brought five competitors. Mr. G. Hart, gardener to H. Head, Esq., Buckingham, Shoreham, was first with well-grown examples of *King of the Blues*, *Lord Derby*, *Von Schiller*, *Seraphine*, *Czar Peter*, *La Grandesse*, and *Lord Byron*. Mr. J. Hill, gardener to M. Wallis, Esq., Springfield,

Withdeane, was second; and Mr. W. Jupp, gardener to G. Boulton, Esq., Torfield, Eastbourne, third. The first prize for six varieties of Hyacinths was awarded to Mr. G. Sims, gardener to C. J. Inwood, Esq., The Retreat, Dyke Road, Brighton, who staged fine examples of *La Citronière*, *Lord Macauley*, *Paix de l'Europe*, *Von Schiller*, and *Grand Vainqueur*; Mr. Anderson, gardener to B. J. Rogers Tillstone, Esq., Mousie Coombe, Lewes Road, Brighton, and Messrs. J. Peed & Son, Roupell Park Nurseries, Norwood Road, S.E., being second and third respectively. Mr. Murrell, gardener to Mrs. Macdonald, Manor House, Preston Park, Brighton, was adjudged the first prize for twelve pots of Tulips. In this exhibit splendidly flowered examples of *Chrysolora*, *Joost Van Vondel*, *Cottage Maid*, *Keizers Kroon*, *Artus*, and *La Reine* were staged. The second and third prizes went to Mr. Fry, gardener to C. W. Catt, Esq. (President of the Society), 52, Middle Street, Brighton, and Mr. Hill in the order named.

For six pots of Tulips Mr. Hart was first, showing *Thos. Moore*, *Proserpine*, *Duc de Berlin*, *Tournesol*, and *Ophir d'Or*. Mr. Rupert Miller, Southdown Nursery, Shoreham, was first with twelve pots of *Narcissi* in flower, Mr. Hart being second; both exhibits were very good.

FIG. 58.—PRIMULA CALYCINA. (See page 300.)

There were four competitors in the class for six pots of Freesias, and the competition was keen, Mr. Hart being first with some grand pots. Mr. Jupp was second, and Mr. Fry third. For twelve pots of *Lily of the Valley* the prizes were again closely contested, Mr. J. Gore, florist, Polegate, being accorded the first, Mr. R. Miller second, and Messrs. W. Miles & Co., West Brighton Nursery, Hove, third. In the class for six pots *Lily of the Valley* Mr. Jupp was first, and Mr. E. Meachen, gardener to Mrs. Armstrong, Woodslee, Withdeane, second. *Scillas* were shown by Mr. Hart only, who was awarded the first prize. For six pots of *Lachenalias* Mr. Meachen was first, Mr. Fry second, and Mr. A. E. Coleman, 51, Shaftesbury Road, Brighton, third. Each of these exhibits were excellent, the plants being very finely grown. Mr. G. House, gardener to F. Mowett, Esq., C.B., Withdeane Hall, Patcham, was first for six *Amaryllises*, showing amongst others *Flora*, *Queen Elizabeth*, and *Delbata*. Mr. Hart was second.

*Gloxinias* were magnificent, Messrs. J. Peed & Son being first, Mr. G. House and Mr. Anderson second and third respectively. Messrs. J. Peed & Son were again first for *Cyclamens*, and Mr. Meachen second. Mr. Murrell was awarded first prize for six *Cyclamens*, his exhibit being in every way an excellent one; Mr. G. Miles, Victoria Nurseries, Dyke Road, Brighton, was second. For a pan of *Anemones* Mr. Hill was first, Mr. Meachen second, and Mr. J. Lewis, 37, Preston Road, Brighton third. These pans were very fine indeed in every case. Messrs. W. Miles & Co. were an easy first for six pots of *Delyra spectabilis* the second and third prizes going to Messrs. Jupp and Hill in the order named. For twelve pots of *Spiræa japonica* the competition was very keen, Mr. House being eventually awarded the first prize, Messrs. J. Peed & Son the second, and Mr. R. Miller the third. Mr. G. Hart was first for six *Spiræas*, Mr. Murrell second, and Mr. Fry third. There was only one entry in the class for a pot of standard *Mignonette*, for

which Mr. Baker, gardener to F. H. Brady, Esq., Wykeham, Burgess Hill, was awarded second prize. Pots of Mignonette were grandly represented by Messrs. J. Peed & Son, who very easily won the first prize; Mr. A. Golding, gardener to Horace St. Geo. Voules, Esq., Uplands, Dyke Road, Brighton, being second; and Mr. Hill third.

For twelve Cinerarias, Mr. Murrell was first with some grand specimens, Mr. House being second, and Messrs. W. Miles & Co. third. Mr. G. Miles was first for six Cinerarias, and Mr. Meachen second. There were only two entries in the class for twelve double Primulas, Messrs. W. Miles & Co. being first, and Mr. Murrell second. For six double Primulas, Mr. House was first. Mr. Hill was first with twelve single Primulas, very fine plants. Mr. Jupp was awarded the first prize for six single Primulas. There were two competitors in the class for six pots of double Stocks, Mr. H. V. Smythe, Centurion Road Nurseries, Brighton, being first, and Mr. Hill third. For six Show Auriculas, Mr. S. Tilley, 13, Clermont Road, Preston Park, was first. Mr. Anderson was first with six Alpine Auriculas, showing excellent plants. In the class for twelve Polyanthus, Mr. Baker was first; Mr. Wickham, gardener to J. K. Nye, Esq., Highlands, Keymer, second; and Mr. Anderson third.

The competition was very keen in the class for twelve greenhouse Azaleas, Mr. Murrell being awarded first prize for some magnificently flowered specimens; Mr. Jupp second, and Mr. Golding third. For six Azaleas Mr. Meachen was first, Mr. Sims second, and Messrs. Peed and Son third. In the class for six Ghent or Mollis Azaleas there was but one entry, that of Messrs. W. Miles & Co., who were adjudged first prize for their charming stand. For six Genistas Mr. Wickham was first with very fine specimens, Messrs. W. Miles & Co. second, and Messrs. Peed and Son third. There were seven entries in the class for six Deutzias, Mr. Meachen taking first prize, Mr. G. House second, and Mr. Wickham third.

For six Roses in pots Mr. Meachen was first with magnificently grown plants, Messrs. Peed & Son second, and Mr. Fry third. Show Pelargoniums were excellently shown by Messrs. Peed & Son, who were awarded first prize. Mr. G. Miles being second. Mr. Murrell was first for six double Pelargoniums, showing fine plants. For six Zonal Pelargoniums Mr. Meachen was first, Messrs. Peed & Son second, and Mr. Fry third. Arum Lilies were finely shown by Mr. Murrell, who gained the first prize, Mr. Meachen being second, and Messrs. Peed & Son third. For six pots of Strawberries bearing fruit Mr. Golding was first, and Mr. A. G. Davey, Oakwood Road, Burgess Hill, second.

For groups of miscellaneous plants Mr. J. Turner, gardener to Sir G. Smyth, Wickham Hall, Furze Hill, Hove, was first with a grand exhibit; Mr. Miles second, and Mr. Meachen third. Mr. R. Miller was first for twelve bunches of Narcissi; Mr. Savage, 33, Western Road, Brighton, being second; and Mr. G. Hart third. For boxes of cut flowers, Mr. J. Gore was first, Mr. Meachen second, and Mr. Wickham third. For tables of plants Mr. Jupp was first, Mr. J. Turner second, and Mr. G. Miles third. In the class for six Hydrangeas Mr. H. V. Smythe was first with magnificent examples, Mr. Hill and Messrs. Peed and Son being second and third respectively.

For a brace of Cucumbers Mr. H. C. Prinsep, Buxted Park, Uckfield, was first with Sutton's Matchless, Mr. Golding second, and Mr. G. Helman, gardener to the Right Hon. Viscount Gage, Firle Park, Lewes, third. For a dish of Strawberries Mr. Ball, fruit grower, Shoreham, was first, Mr. G. Helman second, and Mr. Golding third. Mr. Thos. Fairs, gardener to R. Clowes, Esq., Clayton Wickham, Hassocks, was first for two bunches of Grapes; Mr. Kemp, gardener to C. R. Scrasse-Dickens, Coolhurst, Horsham, being second. Lady Downe's Seedling was staged by each competitor.

Mr. H. C. Prinsep sent a fine table of plants, not for competition. Messrs. Balchin & Son, nurserymen, Brighton, staged a magnificent group of foliage and flowering plants; and Messrs. J. Cheal & Son, Lowfield Nursery, Crawley, a fine table of Apples, neither of which exhibits was for competition.

The amateurs' division was excellently represented, the entries being numerous and the competition very keen.

prevent the soil cracking. Keep a sharp look out for red spider, and if any appear on the leaves sponge the affected parts carefully with a softsoap solution, 2 ozs. to the gallon of water; this, though a tedious process, is an excellent remedy, and taken in time effectually prevents the spread of the pest. Painting the hot-water pipes with sulphur brought to the consistency of cream with skim milk is an old remedy for red spider, and very effectual against mildew, but care must be taken not to give a powerful dose, as the fumes are very injurious to the tender skins of Frontignan and Muscat Grapes. Ventilate night and day when the berries begin colouring, and increase it as they approach ripeness, maintaining, however, a circulation of warm, rather dry air until the Grapes are thoroughly finished, when the temperature should be gradually reduced.

*Vines in Flower.*—Muscats and other shy-setting Grapes require a rather high temperature to set freely, the points of the bunches being kept well up to the light, and a free circulation of air with a fair supply of atmospheric moisture to prevent the young foliage suffering under the influence of bright sun. The temperature may be maintained at 70° by night, but with the Vines in good condition free setting is effected with 65°, or even 60° at night, a little air being admitted constantly, and 70° to 75° by day, with 10° to 15° rise from sun heat. When the bunches are in flower they should be lightly tapped on the stem each day after the house has been ventilated an hour or two, or they may be brushed over lightly with the hand, which rids the flowers of their caps, sets the stamens free, and disperses the pollen on the stigmas. If there be no pollen visible as a yellowish dust when the bunches are brushed over with the hand it should be taken from varieties that supply it abundantly, as Alicante and Black Hamburgh, and a large flat camel's hair brush be filled with it and the bunches brushed over after the hand has been drawn over them, refilling the brush with pollen as occasion requires, it being collected on a sheet of white paper turned up at the edges. Alnwick Seedling, Mrs. Pince, Lady Downe's, and other varieties liable to produce small seedless berries should be carefully fertilised on fine days, when the caps part readily from the flowers.

*Late Houses.*—Accelerate the growth of late Vines by making the most of solar heat, as all long-keeping Grapes cannot be over-ripened for keeping sound for some months after they are removed from the Vines, Lady Downe's ripened by early September being quite fresh in May and June. Ventilate early on fine mornings, as soon as the sun acts on the house, and allow the heat to rise to 80° with increased ventilation and plenty of moisture, closing in time for it to rise to 85° or 90° from sun heat on fine afternoons. A temperature of 60° at night will be sufficient until the Grapes flower, when 5° more will be necessary to increase the length of the bunches and produce conditions favourable to the setting of the fruit. Gros Colman, Gros Guillaume, and Alicante set freely; but most other kinds of late Grapes require careful artificial impregnation, they being attended to as before advised.

*Planting Vines.*—When the Vines commence growing is a good time to plant them, they having been cut back in early winter and been kept in a cool house, the growths will be 1 to 3 inches long. Turn them out of the pots, remove all the soil, preferably washing it away, and preserve the fibres. Spread the roots out straight and flat, the soil of the border being brought to the required height, covering the roots to a depth of 3 or 4 inches, working the soil well amongst them with the hand, and giving a good watering at a temperature of 90°, and mulch a foot farther than the roots extend with an inch thickness of lumpy manure. If the Vines have not been shortened do not cut them back now, but remove the buds from the upper portion of the cane down to where fresh growth is desired to issue, and shorten the canes when the Vines are in full leaf. Sprinkle the Vines twice a day, but avoid forcing them into growth until they have formed new roots, as will be indicated by their starting freely, then afford a temperature of 55° to 60° at night, 60° to 65° by day, advancing 10° to 15° from sun heat, closing early in the afternoon with plenty of atmospheric moisture.

*Making Borders.*—Four to 6 feet width of border will be sufficient to commence with, confining the roots to the inside border (if planted inside) until that is fully occupied with roots, when they may be admitted to a prepared width of outside border. For general purposes the borders are preferably partly inside and outside; for early forcing and tender varieties, as Frontignans and Muscats, inside borders only are best, whilst for greenhouses or midseason Grapes the borders may be wholly outside, taking care to protect the stems with haybands. In well-drained soils the Vines will produce excellent Grapes by merely trenching or stirring the ground 2 feet deep, as for other fruit trees, and feeding at the surface. Where the soil is unsuitable and the subsoil wet and cold it will be necessary to concrete the bottom of the border, but it is quite unnecessary to do where the sub-stratum consists of gravel or other porous substance. Place in 1 foot thickness of rubble, proper drains being provided to carry off the superfluous moisture. A thin layer of turves over the drainage will make it secure against the soil choking it, but we prefer a 3-inch layer of old mortar rubbish freed of pieces of wood. Two feet depth of suitable soil is ample. It may consist of the top 3 inches of a pasture where the soil is a good yellow loam, containing a fair per-centage of small stones, as very heavy close soil is not desirable, and this mixed with a tenth of old mortar rubbish, a similar proportion of broken oyster shells, and a like quantity of charcoal will grow fine Grapes, phosphatic and potassic manures being supplied by the surface, with nitrogenic elements after the Vines require aid to growth.

As turf is rich in nitrogen, but deficient of phosphoric and potassic elements, as well as of soda and lime, 10 lbs. of kainit and 17 lbs. of

#### FRUIT FORCING.

*Vines.*—*Early Houses.*—Where the Vines were started early in December the Grapes will be taking their last swelling, and if any of the bunches are too crowded remove a few of the least promising berries with a pair of finely pointed scissors, taking care not to stab any of those left. The inside borders should be well supplied with water or liquid manure, and they must not be allowed to become dry after the Grapes are ripe, as moisture at the roots is necessary for the perfecting of the growth. Choose a bright fine morning for watering, and admit air rather freely, so that all superfluous moisture will disappear before ventilation is reduced for the day. A little short, sweetened lumpy manure may be spread on the surface, to stimulate the roots and

Thomas's phosphate powder may be mixed with each square yard of border 2 feet deep (18 cubic feet), mixing well, and these substances will not only afford mineral matter over a long period, but render others available, and prove useful against predatory larvæ. Basic slag, however, is not desirable for soils other than those containing much humus, as the rich soil of gardens, or considerable vegetable matter, as turf. As a rule it would be much better to rely on the ordinary soil of gardens, over efficient drainage, than to bring in fresh loam, often at great expense, for the production of Grapes.

**Young Vines.**—Those planted last spring will now be breaking naturally, and when the buds have pushed growths about half an inch long a little fire heat will prove beneficial, especially on cold days. Remove all buds except one at each break, retain the strongest and crop lightly, but supernumeraries may be allowed to carry as many Grapes as they are calculated to colour well. Leave the shoots on the permanent Vines about 18 inches apart on both sides of the rods, and pinch the laterals on the extension canes at the first leaf, and sub-laterals may be similarly treated, removing all tendrils, and stopping the main canes at 6 to 9 feet, so as to secure those extents with well developed buds and thoroughly ripened wood.

#### THE KITCHEN GARDEN.

**Globe Artichokes.**—Unprotected clumps are dead in many instances, and all of those that were heavily banked up with either straw litter or ashes were also badly crippled by frosts. The strongest growths, or those which if they escape destruction by frosts are the first to produce flower heads, have quite disappeared, and in their place are numerous weakly growths. Unless the latter are early and freely thinned out they will greatly weaken each other, and the crops be very poor accordingly. The first proceeding should be to well bare the clumps and also the surface roots to a distance of 18 inches, and after the suckers have been reduced to about three, or at the most four to each stool, to cover the roots with a layer of solid manure, returning the soil previously thrown back on to this. It should be remembered that these Artichokes cannot well be grown too strongly, hence the necessity for good dressings of manure, followed later on, if the season promises to be a dry one, with occasional heavy waterings.

**Forming Fresh Beds.**—Old beds soon become incapable of producing extra fine succulent flower heads, and are also the first to collapse in hot dry weather. Young plants, according to the requirements of the establishment, ought, therefore, to be put out every spring and an equal number of old ones destroyed, none being retained on a site for, say, longer than five years. These Artichokes should have a deep and very freely manured root run prepared for them, no vegetable grown standing in greater need of this, or better repaying for the extra trouble incidental to high culture. Ground naturally of a strong retentive character best suits them, and in order to have this in a finely divided state the trenching ought to have been done soon enough for frosts, winds, sunshine and rain to properly pulverise it. If the planting must be carried out on lumpy ground surround the roots with a little fine added soil. When the old stools are bared for the purpose of thinning out the shoots or manuring, that is the time for detaching good side shoots with a few healthy roots attached. These should be planted with a trowel in groups of three each, the groups to be 3 feet apart each way and the plants about 8 inches asunder. None of the stem should be out of the ground, but the heart ought to be kept clear of the soil. If the ground is all dry give the young plants a watering and mulch with straw litter. The majority ought to produce serviceable flower heads in the autumn and abundance of extra strong ones early next year.

**Seedling Globe Artichokes.**—Seedlings are very easily raised, and can be had large enough to produce freely the same season. If the stock of old plants was destroyed last winter or an early supply of seedling Artichokes is wanted for any other reason, the seeds may be sown at once, three or four in every 4-inch pot, and placed in heat. They will germinate quickly, and the seedlings should early be reduced to one in each pot. Before they become badly root-bound, harden off and plant out either as advised in the case of divisions or 18 inches apart in rows 3 feet apart. Given a little attention at the outset, they will grow strongly, and throw up their flower stems early, when the worthless forms should be cut out as fast as they are detected. A late supply may be had by sowing seed now, either in rows or patches, at the distances recommended for the pot plants, thinning out of the seedlings being early resorted to. The Green Globe are the most reliable.

**Asparagus.**—Open-air beds have furnished a surprise, cutting having commenced a month earlier than usually happens. Instead of having to forward it, something has had to be done to retard or to protect the young shoots. The latter when first peeping through the ground are most susceptible of injury from frosts, and during April, if not later, ought to have the benefit of protection. All that is needed is a fairly thick covering of straw litter, this being placed on the beds and lightened up after heavy rains. Such coverings, in addition to protecting the young shoots, also serve to conserve the moisture in the beds during the summer and to keep down weeds. All the shoots that show through the litter ought to be cut in the evening whenever frosts are imminent.

**Planting Asparagus.**—While bright weather is prevalent planting might usually with advantage be deferred, but now that growth is so far advanced the first favourable opportunity that offers for transplanting Asparagus should not be missed. Dull warm showery weather is the best time for doing this important work. Planting on the level answers well in the case of warm light soils, but where the opposite prevails raised beds are to be preferred. In the former instance the

plants may be put out from 18 inches to 2 feet apart in rows 3 feet apart, no pathways or alleys being needed. Raised beds 5 feet wide will hold three rows of plants, the outside ones being 12 inches from the edges, and for an early supply beds 3 feet wide to hold two rows of plants answer well. In either case dispose the plants not less than 15 inches apart. More than ordinary pains should be taken in planting. Either open wide drills or single holes, making the bottoms slightly rounded, set the plants on this, and spread out the roots evenly, covering with good fine soil, the crowns being eventually disposed 2 inches below the level. It is a mistake for salt or any other strong artificial manure to come into contact with the newly disturbed Asparagus roots, but a liberal sprinkling of fish bone manure would prove most beneficial. There must be no cutting from Asparagus before the plants have been in their present quarters at least two clear seasons, a little self-denial in that direction well repaying in the end.

**Sowing Asparagus Seed.**—It is not yet too late to sow Asparagus seed, and it may be done either in shallow drills not less than 15 inches apart, with a view to have abundance of plants for forming fresh beds a year or two hence, or the seeds may be sown where the plants are to remain permanently, the rows being arranged the same distances apart as advised in the case of putting out plants. If the drills are dry when opened give a gentle watering prior to sowing, and the seed will then germinate quickly and strongly.

**Potato Planting.**—The weather has been very favourable for this work, and all may now be completed. Only the short-topped quickly maturing varieties are suitable for planting with a view to cropping between with Brussels Sprouts, early Broccoli, autumn Cauliflower, and Borecoles. Arrange the rows of Potatoes not less than 3 feet apart.

#### PLANT HOUSES.

**Allamandas.**—Those that it is intended to train under the roof should not be allowed to start away with too many shoots, or else they will before the season is over become a crowded mass and overshadow plants growing beneath them. Not only should the shoots be well thinned, but attention is needed in this matter every time they show flower and start again into growth. Those that are growing freely must have liberal supplies of water, and all that have not yet commenced flowering should be well syringed in order to keep the plants free of yellow thrip.

**Stephanotis floribunda.**—Plants that are growing freely should not be kept too hot and moist, or else the growing ends will turn yellow and die. Employ less fire heat and give air freely during fine days to induce firm sturdy growth, which is then certain to flower profusely. Plants that have their pots full of roots and are growing and flowering should have weak stimulants every time water is needed. Syringe freely in order to keep the plants free from mealy bug. If any make their appearance syringe with the petroleum and water solution, but shade the plants until the oil has evaporated.

**Clerodendron Balfouriana.**—Specimens that have flowered should be encouraged to grow by placing them in moist heat. Grow the plants fully exposed to the sun, and if possible train the growing shoots beneath the roof. They ripen better and flower more profusely by this method than when the growths are trained closely to trellises of various shapes. Young plants raised from cuttings should be potted, as they need more root room; train these under the roof to a thin cord, so that they can be thoroughly ripened. Plants in 7-inch pots are most useful for the decoration of the conservatory, and well repay the trouble involved in growing a batch from cuttings annually.

**Poinsettias.**—Old plants that were cut back will have started into growth sufficiently to have the soil shaken from their roots and be repotted. Directly these are started give them an intermediate temperature. Young plants raised from eyes and placed thickly together in pans will be rooted; these should be potted singly, or a good number of their roots will be destroyed in dividing them.

**Nepenthes.**—Do not allow bright sun to reach these plants, or their foliage will quickly be browned. Syringe freely to keep the foliage free from thrips, and never allow the plants to approach dryness at their roots. Pinch all shoots that have made more than four or five leaves, or they soon fail to produce pitchers. When healthy all shoots that are pinched soon break again into growth. It is only by pinching them freely that large bushy plants that will continue to pitcher can be produced.

**Justicia flavicomma.**—The earliest cuttings will be well rooted, and should be transferred into 4-inch pots. Start them again in brisk heat, and then place them in an intermediate temperature. Insert another good batch of cuttings singly in thumb pots, and place them under handlights where they can be shaded from the sun until they are rooted.

**Tydas.**—Cuttings of evergreen kinds such as Madame Heine and others should now be rooted in thumb pots. They root so freely that when the necessary stock of cuttings have been obtained the old plants may be thrown away. When the cuttings are rooted and have grown a few inches in length the points may be re-rooted, when those from which the tops have been taken will branch freely and make large bushes.

**Gardenias.**—Plants that have flowered may be pruned back and started again into growth in brisk heat. If they can be given gentle bottom heat all the better until they have begun to grow, when they may be repotted if they need it. When cut back, if infested with scale or mealy bug, syringe them freely with petroleum and water, using 2 ozs. of oil to each gallon of water.

# THE BEE-KEEPER.

## APIARIAN NOTES.

### THE WEATHER AND BEES.

WE have had another week of cloudless sky, with a day temperature ranging from 56° to 68°, and the night temperature from 27° to 30°. The days are hazy, which hinders the bees from being so active as they would with a clear atmosphere. In fact, they are not nearly so active as they were during the two last weeks in March, although the Gooseberry blossoms are well out now. No doubt the seeming inactivity of the bees is due to the electrical state of the atmosphere. On the evening of the 6th the flashes of lightning were frequent, and the day was sultry. Not more than twice during the past half century has there been so much fine weather at this same time of year, or so many high temperatures.

### THE CONDITION OF HIVES.

Everywhere, if casualties through carelessness and bad management are exempted, bees are generally speaking in a forward state. From the Midlands I hear of supers being added, and in many places in Scotland hives are ready for them or swarming. In an apiary only half a mile distant from me, but out of the smoke, the hives are sweating greatly, and increasing in weight. They are all of Tunisian blood. A gamekeeper who lived in Africa, although not a bee-keeper, recognised the bees in another good apiary as Tunisians, not "Punics," as the owner called them. I will endeavour to have an interview with him for the purpose of acquiring information.

### PUNICS AND BRITISH BEES.

I am certain that the first cross Punics are the most industrious bees imported into this country, and they are much milder in temper than the original British bee, which, however, is probably extinct in this country, notwithstanding assertions to the contrary. I appeal to all who have pure Punics to report their doings and behaviour from now onwards until the end of the season, so that notes may be compared, and the facts made known. It is a foregone conclusion that the crosses are superior, but it is desirable we should know more about the pure bees in a good season.

### QUEEN CELLS.

These are raised by the Punics in great numbers. In order to overcome the difficulties which arise through that, and avoid the unnecessary delay caused by it, the bee-keeper should examine stocks on the ninth day after swarming and destroy all surplus queen cells. This advice applies to other varieties as well.

### HONEY—A CAUTION.

Some bee-keepers are apt to be deceived with the quantity of honey gathered during a spell of fine weather such as we are enjoying. They should not trust too much to appearances, but make sure of the amount gathered and stored. Bees are increasing rapidly at present, which adds weight to hives, but at the same time food consumers, the stores being consequently reduced much quicker than some may imagine, and if inclement weather sets in the hive, unless fed, may be doomed to destruction. Hives are earlier than is usually the case, and it would be a mistake to delay too long the feeding if it be required. When the fruit blossoms are available to the bees the latter seldom require after assistance, but it is prudent to make sure on the point.

### EXTRA APPLIANCES.

With an extra fine summer it is astonishing the space bees fill with combs and honey. Larger and extra hives and supers should be provided, so that no difficulty may arise nor disappointment be experienced as the season advances when hopes run high.—A LANARKSHIRE BEE-KEEPER.

### RE-QUEENING—ARTIFICIAL SWARMING.

I SHOULD like to ask "A Lanarkshire Bee-keeper" whether I ought to re-queen my two hives of English bees. They were bought twelve months ago as stocks headed by two young queens. We had no swarms last year, and I may say that I never had bees with the same amount of brood on the 1st of April. What I wish to know is whether or not I should introduce new ones, and when. Could I rear my own, or purchase one? A few hints on artificial swarming would be appreciated.—H. RICHARDSON.

[It is not necessary to requeen hives that have queens of 1892 until the end of June or beginning of July, pre-uming they are taken to the moors. In the case mentioned we should let them swarm, then on the ninth day afterwards form nuclei by dividing combs, bees, and brood into as many as are strong enough. If successful with the nuclei it will be the better plan to depose the old queens, and introduce queens of the nuclei when laying; this

gives youthful blood, and the best results follow. The proper time to rear queens is at the natural swarming time, when the hives are crowded with bees and the combs full of brood or honey.

Artificial swarming should be performed when the bees and hive are in a fit state for it, and then only, otherwise the hopes of profit disappear. Straw hives should be inverted upon some platform or other contrivance. An empty hive is at first placed over the mouth of the stock, and a few raps on it will cause the bees to fill themselves and ascend into the empty hive; when they begin to do this draw it to one side and rap with the other, or with a hinge made for the purpose the two hives may be fastened together, and the empty one held at the proper angle, allowing a full view of both hives, and freedom with both hands. In all artificial swarming there is a great tendency for the bees to search out the old stock and go back to it. It is therefore advisable to be sure that plenty of bees are left to tend the brood, and remove it a considerable distance from the old site, which the swarm should occupy. Repeatedly I have had swarmed stocks removed within doors, yet the bees found them out.

With frame hives the task is more simple. Remove the frame with the queen on it, place it in a new hive on the site of old stock, then brush gently, or shake from the other frames the proper number of bees on to the swarm, and remove the stock as with the straw hive. Put a frame filled with foundation in the vacancy, and form the nuclei as advised above.—A. L. B. K.]

## TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough.—*Softwooded Stove and Greenhouse Plants.*

W. Paul & Son, Waltham Cross.—*New Roses and Florists' Flowers.*

John Laing & Sons, Forest Hill, S.E.—*New and Rare Clivias.*

••All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Compost for Tea Roses (F. D.).**—Turfy loam of medium texture, a sixth part each of crumbled manure and leaf soil, with a little crushed lime rubbish and wood ashes for ensuring porosity, will grow Tea Roses in pots well if the plants are kept quite free from insects and good judgment is exercised in watering. In the absence of either of those essential conditions, the best of soil will not produce healthy growth and good blooms. A pound of crushed bones mixed with half a bushel of the compost would improve it considerably, but excellent results are obtained without such addition, any extra support needed by the plants being afforded by top-dressings or liquid manure.

**Layering Chrysanthemums (An Amateur).**—The process is perfectly easy, and with ordinary attention you need have no fear of failure occurring. Plant a few old plants out of doors in a row; let them grow as wild as they choose till the month of July; then take as many pots as plants are required, and plunge them, filled with some rich soil, into the ground, at such a distance from the plants growing in the ground as will allow the tops only, when bent down, to reach the pots; bring them carefully down, and peg each branch firmly into the soil. Leave about 2 inches of the top out of the soil. If the shoot is branched it is well, but if not it must not be topped, because there is some danger that the layer may continue to grow and not flower if topped so late in the season. The aim of this mode of propagation is to make them flower when very dwarf; and, therefore, the layer should have buds upon it just visible at the time when the layering is performed. Keep the soil in the pots moderately moist till roots are formed, and after that water more freely. When it is certain the layers have made plenty of roots cut them off from the parent plant, and remove them into a frame or pit deep enough to receive them. Should they flag during the day, give a sprinkling of water, and shade for a day or two till they recover; then give air and water freely. They will then be good plants, about a foot high, with, perhaps, six or ten flowers on each.

## MAKING BORDERS AND PLANTING VINES.

A COMPOST of five cartloads of sound turfy loam, one cart-load of lime rubble, one of wood ashes, one of horse droppings, and an ordinary sized barrowful of fresh soot will suit the requirements of the Vine admirably. The whole should be well mixed before being formed into a border. In this mixture Vines will grow freely and yield satisfactory crops of fruit for several years, other things being duly attended to; but should the cultivator be disposed to add 2 cwt. of half-inch bones to the above ingredients it will be all the better for the Vines. Where indifferent loam has to be used in the formation of Vine borders two bags of Thomson's Vine manure should be added to every eight loads of the compost described, turning the whole over two or three times before use.

In making a Vine border the first point to be determined is the width and depth it shall be, also ascertaining the highest water level of the place, so as to keep the bottom of the border well above that point. According to my experience the majority of Vine borders in England, Ireland, and Scotland are made much too wide and also too deep. Who, I ask, has ever found a Vine border 12 or 15 feet wide, 3½ feet deep at back, and a little less than 3 feet deep in front, full of roots at any time? I never have. Consequently I have, in recent years, considerably reduced the width and depth of some of the Vine borders here with advantage. A border 7 feet wide, 2 feet 9 inches deep at the back, and about 6 inches less in the front from the concrete bottom will afford ample space for the roots of the most vigorous-growing Vines.

The bottom of the border should have a fall of 6 inches from the back to the front, at which point a series of deep gutter bricks should be set in cement on a level with the bottom of border and connected with a drain for carrying off superfluous water. Unless the subsoil consists of stone or chalk it will be necessary to place 6 inches thick of concrete, composed of five parts of gravel to one of stone lime, well mixed on the bottom. A like thickness of chalk pounded well together will answer the same purpose. Six inches thick of brickbats, broken somewhat fine on the top, should be laid on the hard bottom for drainage, covering this with turves from 1 to 2 inches thick, grass side down, thereby completing a quick and sound drainage. In forming the border make it in sections 3½ feet wide from the front wall of the vinery, keeping the soil in position with a side wall built of turves, and making allowance for the loosely thrown together soil subsiding 6 or 7 inches within a few weeks from the time of making the border. If the border is an inside one the soil should be in the house say a week before planting is done, to allow of its becoming slightly warm before being brought in contact with the roots of the young Vines when turned out of the pots.

Although Vines may be successfully planted any time during the interval from February to the end of September, according to circumstances, the present is, in my opinion, the best month in the year for doing such important work, as the Vines are then less liable to experience any check in the process of being transplanted. The external and internal conditions admit of an equable and genial temperature in the soil and house being maintained with but little assistance from the hot-water apparatus, and thereby favouring a sturdy growth being made, other points being attended to

in the way of ventilation and the distribution of moisture at the roots and in the house during the heat of the day.

Before planting the Vines make a series of holes 2 feet apart, beginning at 2 feet from the end, between the front wall and the hot-water pipes, the entire length of the border. If the border is an outside one make the holes close up to the wall opposite the spaces cut therein for the Vines to be taken into the house. Then provide a sufficient amount of rather fine soil of about the same temperature as that in which the Vines are growing in the pots for placing around them when being planted. Assuming the Vines are of this year's raising from eyes, or if "cut-backs" that they had been shaken out early, root-pruned, and repotted, there will be no necessity for disturbing the roots in planting, but, on the contrary, turn them carefully out and plant them 1 inch deeper than they were in the pots; the permanent Vines midway between the rafters, and those for yielding a crop of fruit next year between them, making the soil firm. Put a stick to each Vine for support and secure the rods loosely to the trellis, but leave them sufficiently long to subside 6 or 7 inches with the soil. Give sufficient tepid water through to settle the soil about the roots, and then a surface dressing of horse droppings or other short manure to the thickness of 2 or 3 inches.

In the event of the cultivator having to plant one-year Vines obtained from the nursery, or home-grown which had not been shaken out and treated as described above earlier in the year, it will be necessary to disentangle and shorten back the roots, then spread them out in every direction with a slight inclination downwards, cover with 6 inches of soil, and give water as recommended above; also afford shade from sunshine with mats or other heavy material during the heat of the day until the roots commence working, maintaining a close moist atmosphere and syringing the Vines slightly three or four times a day to keep the foliage fresh and encourage new growth in root and branch.

After the Vines have taken well to the new soil the shading should be discontinued, and plenty of fresh air admitted to the house during the heat of the day, closing early in the afternoon, say from 3.30 to 4.30, during the next four months, with plenty of water distributed in the house, and thoroughly syringe the Vines at the same time. Admit a little air in the morning when the thermometer has registered 75°, afterwards increasing and decreasing the amount according to the rise and fall of the temperature. Also give tepid water at the roots in proportion to the daily increasing requirements of the individual Vines and the lengthening hours of light and increasing power of the sun's rays.

During the months of September and October air should be more liberally admitted to the houses, leaving the top and bottom ventilators open a little at night, and maintaining altogether a drier atmosphere in the house until the Vines have shed the leaves, with the object of thoroughly maturing the wood. Let the stopping and pinching of the young growth be proceeded with on the lines laid down at page 281, under the heading of "Pruning Vines—an Object Lesson."—H. W. WARD, *Longford Castle Gardens*.

## THE SPRING IN A SCOTTISH MANSE GARDEN.

SPRING is the most interesting season of the year. Autumn is, indeed, more impressively beautiful, with its gorgeous woods and ethereal sunsets; but its loveliness is everywhere touched and saddened by the presence of decay. Spring, on the other hand, is essentially a period of hope; it tells of bloom and beauty yet to come.

Since I wrote my last article to the *Journal of Horticulture* (page 251) on this fascinating subject the weather has been exquisite, at least by day; though (perhaps on the principle that every gift has its penalty) it has been for purposes of growth and development too prevailingly dry. The influence of the heavy

dews which fell during the evenings has invariably been towards early morning almost neutralised by frost. In my garden, which has the great advantage of absolute protection from north and east winds, some plants have been almost absolutely stationary; while others, like the gigantic Lily of the Himalayas (*Lilium giganteum cordifolium*), are developing with great rapidity. Of all my floral possessions the above is the most interesting. It has taken three years in accordance with its unique yet invariable custom to build up its present immense flowering bulb, and now it is beginning to throw out successively its magnificent heart-shaped leaves. My other Lilies, such as *auratum*, *speciosum*, *longiflorum*, *umbellatum*, *Martagon*, and *Krameri*, are of somewhat slower growth but considering the excessive dryness of the season they are doing tolerably well.

"Longsleeps," says Tennyson in his immortal "In Memoriam," "the summer in the seed." But this assertion is hardly expressive of the rapidly germinating *Convolvulus minor*, which, sown less than a week ago, is above the ground to-day. The exceedingly graceful Shirley Poppy, which is just the wild flower of that name introduced into our gardens and improved by cultivation, seems also to be a notable exception to the general rule.

Should April showers come soon—falling like mercy, as depicted by Shakespeare, "upon the place beneath"—Roses will be exceptionally early this year. With me Duke of Edinburgh, Sir Garnet Wolseley, Belle Lyonnaise, Marguerite Dickson, Reynolds Hole, and many others have long been in leaf; and several buds are already very prominent on that earliest of all Roses, Gloire de Dijon.

In a recent letter, abounding in characteristic flashes of humour, the Dean of Rochester (whom I am to have the pleasure of visiting next month) gave me the parentage of Reynolds Hole, one of the most exquisite dark Roses in cultivation, which bears his honoured name. "It comes," he says, "from Cheshunt, and is closely affiliated to the Duke of Edinburgh. It is, like many other beauties, uncertain, coy, and hard to please, yet exquisitely lovely when in a good humour."

One of the latest additions to my miniature rosarium is the Salamander Rose, described in several horticultural journals as a "gorgeous crimson" from Waltham Cross in Hertfordshire. It is like its distinguished predecessors, Mrs. John Laing, Marguerite Dickson, and Mrs. Paul, which it resembles not in colour though it has many of their finest attributes—a gold medallist of the National Rose Society.

Another valuable recent acquisition is a bed of modern Pansies and Violas, received from the great Rothesay cultivators of those flowers, of which my special favourites are the Duchess of Sutherland, the Countess of Hopetoun, the Countess of Kintore, Crimson King, Ardwell Gem, and Duchess of Fife. The last mentioned is an especially charming variety, a beautiful shade of primrose, distinctly edged with blue. The Viola blooms incessantly from March to November, and amply repays the most assiduous attention. It is a modest contemporary of the vernal Daffodil, and blooms with equanimity upon the grave of the latest autumnal Rose.—DAVID R. WILLIAMSON.

## INSECTS OF THE FLOWER GARDEN.

(Concluded from page 108.)

SOME years ago, before London had assumed its present huge proportions, and when it was belted around with many acres of suburban market gardens, those that had houses near these frequently complained of the host of flies that infested their rooms. This was to be accounted for by the large quantities of natural manure used, in which the flies found a breeding place, especially the common house fly and the yellow dung fly. Artificial manures have diminished the multiplication of flies in gardens; but they are always favourite resorts of the Muscidae, or what we call the flies proper, insects very diverse in size and form, yet marked by a family likeness. Various are the causes that bring them into our flower gardens. Many are seekers of honey, others come in pursuit of smaller insects, and a few appear in the capacity of bloodsuckers if they have the chance of attacking anyone. A large number amongst the tiny species are, while larvæ, producers of galls, or leaf-miners; but they are only disfigurers, and do not really weaken or kill plants.

It is likely there are flies which help to fertilise flowers, but their agency is not so marked as is that of the bee tribe. Some plants of the Composite order, allied to the Chrysanthemum, and the peculiar aroma of which has a repellant influence on bees, are much visited by some of the larger flies. But flies have their fancies, and the house or domestic fly is found to have a dislike to the smell of most Pelargoniums, so that if a row of these plants is placed outside a window, even if the sash be raised, very few

flies will cross them to enter a room. Frequently this fly is accused of "biting" people indoor or out; but in fact all it does is to settle upon the skin should it happen to be moist, and take up a drop or two with its fleshy sucker. But a fly that does frequently "bite" or puncture people when sitting in gardens is the stable fly, or *Stomoxys calcitrans*, a fly bred from manure and exceedingly like the common fly, but rather more hairy. This fly has a slender and sharp proboscis, by which it wounds men and animals; but it does not seem to inject a poison, as does the gnat and the flea.

Allied to the house and bluebottle flies are the species in the genus *Tachina*, of which we have more than a hundred, varying in size from the eighth of an inch to half an inch, some of metallic lustre, but the majority of dull colours, powerful-looking insects, which probably are of carnivorous habit as flies, and in their larval state certainly parasitic in habit. Their proceedings resemble those of the four-winged ichneumon flies; they deposit eggs on the bodies of other insects, and the grubs burrow in, gradually killing the victim. Fifty or more of them have been extracted from the body of one caterpillar, and they effect the destruction every year of part of those caterpillars that are common in flower gardens. What is more remarkable, there are some species that select as their special objects of attack individuals of the beetle race, even choosing hardish species of the weevil kind. In a way which is not explained yet, one species of *Tachina* manages to deposit eggs upon spiders, and thus revenges, to some degree, the injuries which flies suffer from these foes. *T. ferox* is a great hunter of caterpillars; it is a fly with a grey head, a brown thorax, and a yellow abdomen that appears as if polished. Another we sometimes notice is *T. grossa*, which we might take for a small black humble bee; it is adorned with some reddish hairs. We may regard the *Tachina* group of flies favourably, whether they appear amidst the flower beds or in the kitchen garden. The winter season is generally passed by them in the pupal condition under the earth, and these, with some other useful insects, are unavoidably killed occasionally by the methods adopted for the removal of hurtful insects from garden soil.

Flies of the genus *Anthomyia* are called flower-lovers, for they resort to flowers during the summer season, very often in little swarms, but they are not predatory, and regale themselves upon the nectar. Most of them are small, greyish brown, black or dull red, some being stout-bodied, some rather slender. In habit the larvæ vary, many of them live in decaying animal or vegetable matter, and occasionally attack bulbs or roots which are not decayed. Other species mine the leaves of garden plants, such as the Columbine and Honeysuckle, and some again produce galls upon the leaves or stems of plants, chiefly of the Composite order. There is a well-known pest to farmers, named *A. Betæ*, which mines the leaves of the Mangold; to this genus also belong the Cabbage, Onion, and Lettuce flies, and they resort to the flower garden, though not breeding there. Some of the larvæ of *Diplosis* have a curious habit—they live upon aphides, and so move about upon the surface of leaves amongst their prey. They have no jaws, but somehow draw in the juices of aphides by suction, and they travel in a succession of jumps, made by means of bristles along the body. In some species the larvæ are viviparous, like the aphides, during a part of the summer. False eggs occur within the larva, which increase gradually till the entire body of the parent is distended so that it bursts, and young larvæ issue forth to finish their growth by aphid food. This would seem to be a wise provision of Nature to multiply the numbers of an aphid killer just when they are most prolific.

Some of the flies of the genus *Tephritis*, though they are rather small, attract our notice when they settle upon flowers by the lustre of their eyes and the markings upon their wings, which, if examined with a magnifier, are seen to be curiously spotted or banded in different colours. They are rather objectionable visitors, as the larvæ burrow into the leaves of some herbaceous plants and produce blisters or galls, so that they fall off if not removed. When full grown they descend to the earth, and there become pupæ. It is, therefore, desirable to check the increase of these and other larvæ of flies that disfigure or damage leaves by picking and burning those we have discovered to be infected, before the insects in them have had time to emerge. The garden Pea is one of the plants resorted to by these flies, and the species of *Lobelia* and *Silene*. We have a tolerably good means of knowing those flies that are predatory in habit. As a rule they do not hover above flowers, but go from one to another by leaps, half flying, half walking, or else they run actively over leaves and flowers too with wings raised perpendicularly, like the pretty little shining species *Sepsis cynipsea*, which is so frequent in gardens about June, and destroys lesser insects.

Before leaving the fly order I may mention an insect which is sometimes called a fly, though it is really akin to aphid and coccus,

and a true bug though winged. It was not referred to in connection with that tribe because I was not then aware the insect occurred in flower gardens, but I have now been informed it has been found infesting Carnations and other flowers. This is the *Aleyrodes*, of which we have two British species, a tiny creature that has the wings covered with white dust, and holds them horizontally. It is well known also as a pest to the Tomato, and, like the little thrips, by its activity and its numbers it can do much mischief in weakening plants.—ENTOMOLOGIST.

## PRACTICAL HINTS ON MELON CULTURE.

(Continued from page 291.)

To secure the proper fertilisation of individual blooms is a matter by no means difficult to perform, and yet a full even crop of Melons is the exception rather than the rule. This is fully accounted for by the fact that if some of the flowers are fertilised a few hours before others on the same plant, the fruits from the latter will drop after swelling slightly. This is not in consequence of fertilisation being improperly performed, because if the leading fruits are removed the later ones will swell satisfactorily. It is, however, a peculiarity of Melons that if a few fruits take the lead and are not speedily checked by bending the shoots as previously advised, no others will swell until these early fruits have reached the first stage of their development. This will show how important it is to have the requisite number of flowers fully expanded at the same time before artificial fertilisation is attempted.

When the flowering stage is reached the house should be kept rather dry, a moderate circulation of air being given, so as to have the pollen dry by midday. The staminate flower should then be picked from the plant, have the corolla removed, and be placed upon the stigma of the pistillate flower. Before doing so, however, I always like to touch the anthers on the back of the hand, to make quite sure the pollen is dry; if it is not the flower should be rejected and another tried. This simple test will often prevent much disappointment. Some cultivators keep the atmosphere of a Melon house excessively dry during the flowering period, and are rewarded for their pains by a colony of insects shortly after. The plan I have practised very successfully for several years is on bright mornings to damp the floors early and then withhold moisture till an hour after the flowers have been fertilised; the ventilation is then reduced, leaving a crack at the top of the house, the floors are damped lightly, and the plants sprayed with the syringe whenever this can be accomplished without wetting the pistillate flowers. Should the weather prove dull a good amount of heat is kept in the hot-water pipes, and the floors of the house and leaves of the plants in the driest positions only are syringed.

As soon as a good set is obtained the plants may be thoroughly syringed twice daily in bright weather and once during dull days. When the fruits are beginning to swell freely early closing, with abundance of moisture, should be practised, as it not only hastens the growth of them, but also does much toward securing large handsome specimens. It is perfectly safe to close a Melon house at 2 P.M. during the hottest day in summer, provided abundance of moisture is used both on the floors and plants. Should evaporation speedily take place another syringing ought to be given an hour after on very bright days.

I have tried many methods of supporting the fruits, but consider none better than accomplishing it by means of three pieces of string or thick raffia grass tied to the wires and twisted together under the centre of the fruit; as the latter swells the strings can be slightly lengthened. I like to thoroughly examine the supports to every fruit, when colouring begins, to see that each is perfectly upright and secure; when this is not the case fine fruits sometimes have a provoking way of breaking away at the stem. To make them secure against this it is a good plan to fasten a piece of raffia grass around each fruit about half way up, twisting it round each of the vertical strings, and drawing it tight enough to fit close to the outline of the fruit; it is then perfectly safe from falling or breaking away at the stem.

Watering is without doubt one of the most important operations connected with Melon culture. No matter how well all other details are attended to, if the watering is improperly performed mediocre if not disastrous results will follow. During the early stages of growth before roots have become plentiful great care should be exercised in applying it, as it is better to err on the side of dryness than in the opposite direction; but when the fruits are about half grown roots become extremely active. Then if water is withheld for only a few hours after it should have been given a stunted tough-skinned fruit is the result, and frequently the plants show signs of distress for a long time after, and can only be prevented collapsing altogether by careful shading.

Perhaps the stage at which healthy Melon plants require the most water is when the fruit is netting, for by that time the soil has become thoroughly permeated with roots, and the slightest check caused through drought will then spoil the natural character of the netting. Instead of being small in the mesh and evenly marked all over the fruit, large cracks are produced here and there, through which a gummy exudation may be perceived shortly after water is given. The evil often does not end here, for many of the small roots having been destroyed the plant becomes unable to support a heavy crop of fruit without showing signs of flagging and with fewer roots; these being also lessened in activity, much less moisture is extracted from the soil, except on the surface, where evaporation is rapid. This often misleads an anxious cultivator, and induces him to apply water before it ought to be given, in the hope that flagging may be prevented; the soil then becomes thoroughly sodden and the plant succumbs. In nine cases out of ten this is attributed solely to overwatering, whereas that is only the secondary cause, the root of the evil being neglecting to water soon enough.

Withholding water while the fruits are ripening is, without doubt, very much overdone. If the plants are kept in good health, and a little growth allowed to extend, no lessening of the supply need take place till the fruits are evenly coloured, and then it should be only slightly reduced. When they give out a rich aroma I prefer to cut the fruits and place upon a dry shelf for twenty-four hours before sending to table. A good deal of discretion must be exercised as to the exact time when the fruits of each variety should be cut, for they differ considerably in that respect, according to the thickness of their skins. Hero of Lockinge requires to hang longer than any variety with which I am acquainted.—LABOR OMNIA VINCIT.

(To be continued.)

## CUCUMBERS FOR MARKET.

IN modern horticulture the tendency to simplify treatment without limiting production is very marked. Elaborate cultivation, once the rule, is now fast becoming the exception, and good returns can be secured without the extensive and complicated process formerly regarded as indispensable. The improvement I have indicated is easily seen in the rapid development of the Cucumber as an article of commerce.

The growing demand for Cucumbers, if it has not created a new industry, may safely be asserted to have made immense advances on an old one. Probably Cucumbers enter the markets now by the hundred where a few years back they did not amount to dozens, and their production increases largely yearly. On the other hand, I see no reason to doubt that the demand keeps pace with the supply. One point in the Cucumber grower's favour is the low price at which the fruit is sold, while the per-centage of profit remains high. The average market price during the summer season may be fixed at 2s. per dozen, and they are extremely unlikely to decline below that figure, which I am inclined to think is the minimum.

Cucumbers are not much in request until April, at which time prices range high. The usual practice is to sow the seed in the first week of the new year. The plants are ready to put out about the middle of February, and come into bearing towards the end of March, and continue till June, when they are cut out and a second batch planted. By these means a continual supply of fruit is furnished until late in November. No bottom heat is used, the Cucumbers being planted on the ground in small hillocks, with hot-water pipes around but not under them, the heating power of which is sufficient to maintain a temperature of 68° in severe weather.

It would seem impossible to bring Cucumber plants into bearing before March without more elaborate treatment, bearing in mind how susceptible they are to checks. But a grower near Enfield has this year taken the lead by fruiting Cucumbers quite a month earlier than usual. No bottom heat was used, the plants being grown in the manner described above. Certainly the man is unrivalled in this particular branch of horticulture, having for some years been foreman in one of the large establishments owned by the Messrs. Rochford. The variety used was the Cucumber which bears the name of those noted fruit growers. The plants do not appear to have been at all weakened for future cropping by the ordeal through which they have passed.

Rochford's Cucumber is in universal request for market purposes in the north of London, and in many places has superseded Telegraph, which at one time was considered the best variety. In the neighbourhood of Enfield we have three of the Rochford Brothers' mammoth establishments and a host of smaller nurseries, in which Cucumber growing holds a prominent place. To judge by the constant additions made to their number of structures the trade is evidently in a flourishing state. I wish I could say the same of the plant nurseries. But I am sorry to add that little or no improvement is going on, and I have come to the conclusion that the supply of plants for market exceeds the demand. The expenses of a plant nursery are much heavier than the establishment devoted to Cucumbers, Tomatoes, or Grapes. The item for flower pots alone must amount to a considerable sum yearly, and for this there is no return, as when a plant is sold the pot is given in with it.—ENFIELDIAN.

## STRAY NOTES.

THOSE who have only taken to Rose-growing within the last six or eight years may probably never have had to prune their plants when in full leaf, as is the case this year in many places, and may be alarmed at the "bleeding" which naturally follows severe cutting down to ripened wood when the sap is so forward. There was some correspondence in the *Journal* on the subject in the last early spring we had (a long time ago!); and the general idea, with which I am quite in accord, was that there was little serious damage done, as the wounds soon heal. It is certainly a dismal sight to see the poor plants next day literally bathed in their own blood, and keeping the soil quite damp round them for several inches. I avoid it by the simple process of not going near them for a week or so, by which time they will have dried up, and then soon commence to break. I remember one year, when my Teas before pruning were a mass of foliage, with great shoots 6 or 8 inches long, that I rubbed off most of these two or three days before applying the knife with a view of checking the sap, but I do not remember that it had much effect in staying the bleeding.

I have noted one advantage of such an early spring in the comparative absence of grubs and caterpillars later on. I have always supposed that when the top buds break early the parent insects lay their eggs in these, which are happily cut away and consigned to the rubbish heap. We shall see if it is so on this occasion.

On April 7th I dug up or rather carefully uncovered and reinstated my Maréchal Niels and standard Teas which had been pegged down, buried and clamped last autumn, and at present I like the look of them. There is not a shoot injured by frost or damp, and they are very backward, having made no sign of growth; they, at least, can be pruned without any fear of bleeding. My Tea buds, which have wintered beneath the straw nightcaps, show a better percentage than usual, with an exception—those on old stocks. When many Tea buds fail in the winter I am sure rosarians of an economical turn of mind, like myself, are loth to throw away strong standard stocks, and so retain them for budding again; but it does not answer as a rule, at least for Teas. Why, when these old stocks make plenty of strong and healthy growth they should fail to take or lose their buds in the winter if they do take is one of the many things I cannot understand, but I have generally found it is so. This spring I have hardly a bud alive on the old stocks, whereas I have quite a fair percentage on those collected the winter before budding.

"Suburban" (page 280) will find that Roses on a south wall are not infrequently in bloom in April in favoured localities. I have had Maréchal Niel fine on the 26th, quite unprotected; but that was a long time ago.

Mr. D. R. Williamson (page 280) is quite in error in supposing that most of the English rosarians, with the exception of Mr. B. R. Cant, grow their Teas and Noisettes under glass. Most would have some in houses; but even Messrs. Harkness, in Yorkshire, grow almost all of theirs out of doors, and I think it may be said that all the principal English rosarians grow the large majority of their Teas entirely in the open air. Even those Teas exhibited at the Westminster National Rose Society's Show in June are almost invariably cut from plants in the open.

I think, too, that it is hardly correct, to be strictly accurate, to speak of the original of a sport as a "parent" Rose. Sports not infrequently revert, even after they have become what are called "fixed" sports. The best Baroness Rothschild that I cut last season came from a Merveille de Lyon plant, which had one or two pure white blooms on it at the same time. And as to Mrs. Paul, Mr. Williamson seems more "mixed" than ever. In the first place, this is not a sport but a seedling from Madame Isaac Pereire (who cannot very well be called "Isaac himself"); and also it seems rather hard on Mrs. Paul that its claim to be a pure Bourbon should be denied because Mr. Williamson has seen its seed parent wrongfully described as H.P. or H.B.—W. R. RAILLEM.

## MISS ORMEROD AND HER WORK.

A DAILY contemporary alludes as follows to Miss Ormerod and her work:—"Miss Eleanor A. Ormerod, who has just issued her sixteenth Report of Observations of Injurious Insects and Common Farm Pests, with Methods of Prevention and Remedy, is one of the most remarkable women of her time. She was born at Chepstow Park, near Sudbury, and from her childhood was excessively fond of observing both plant and animal life, for which the position of her father's property (her father, by the way, being a well-known Cheshire historian, Geo. Ormerod, D.C.L. and F.R.S.) with a mixture of cliffs and shore, woodland and cultivated land, afforded admirable opportunities. Successive illnesses, bringing with them the necessity of quiet occupation, gave also the opportunity, fully utilised, of much reading, enabling her to lay a foundation of

knowledge of botany, entomology, and agricultural chemistry, also of Latin and several Continental languages, and especially a facility in the use of the pencil and brush, all of which have proved of great service to her in her subsequent labours. In 1872 Miss Ormerod was chosen to represent British Natural History modelling from life at the International Polytechnic Exhibition, Moscow, but it was not till five years later that she commenced the series of annual reports that alone have made her name a 'household word' in the agricultural world. At present she carries on what is almost a Government department at her own expense. It is a pleasure to her to reply to any inquiries received from British agriculturists, and a sense of the fact that she has aided them in their struggles is all the reward for which she cares."

The sixteenth Report of Observations of Injurious Insects\* fully sustains the author's reputation as an ardent worker in collecting facts relating to the infections of field, forest, and garden crops, and diffusing information respecting them. It opens with a full page illustration of Turnip affected by the disease known as ambury, finger-and-toe, or club, caused by slime fungus (*Plasmodiophora brassicæ*), from a photograph, and a figure is given on page 148 of a "spindly and much-divided growth to which formerly the name of Finger-and-toe was sometimes given. This is in no way a diseased growth, rather the reverse." No one, therefore, can make a mistake by a comparison of the two illustrations between the diseased and healthy condition of the roots. Photographic illustrations (two) are also given of club or ambury in Cabbage roots, with representations of the spores and embryos of the fungus causing the mischief. We are told that gas-lime is a good preventive of this disease; also that "a mixture of superphosphate and kainit, and an extended system of cropping, will in general prove effective." The latter—change of crop—is (in our experience) the safest and (next to a large dose of gas-lime) the most effectual cure for this disease. Superphosphate is well known as the best manure for Turnips, and kainit by supplying salt (mainly) must strengthen the plant, and potash prove advantageous, particularly on light soils. Salt alone we have found practically useless, and quicklime, though useful against the slime fungus, liberates the fixed nitrogen-forming ammonia—the most volatile of elements. It is stated, however, by Miss Ormerod that "lime and soot have been found to answer for checking club presence," and an instance is given by Mr. Eyden as follows:—"When I first came here I had whole breadths spoilt of Broccoli and Cauliflowers, which have been more subject to attack here than any other green. The first year I was here I found I had got a bed of plants attacked; I pulled all up and burnt them. I simply sowed some lime on the ground and replanted it, dipping the roots of each plant in sooty water before planting it, and when taken up not one root was in the least affected. Since then [Mr. Eyden's experience extends over twenty-two years] I have always treated them in the same way, and have had very few clubs." This is simply the old fashioned gardener's preventive of club root in Brassicas during the past two centuries, and it is doubtful if the ambury or club root was caused by slime fungus, though the lime might be useful against its germs, and the soot acting as a preventive only of the club root caused by Turnip and Cabbage root-gall weevil (*Centorhynchus sulcicola*, Gyll.). These are different infections, as also is that caused by Turnip and Cabbage-root flies (*Anthomyia radicum*, Linn.). Our talented author has got a little "mixed" in her "Turnip and Cabbage-root attacks," and we suggest that they form three definite headings in future reports. The three forms are, however, treated in the sixteenth report in an able manner, but they would carry more weight were each put separately in the scales. These subjects form the first (a frontispiece) and the last in the report, except an appendix treating of Mangolds. The Mangold leaf-blister maggot, the larvæ of *Anthomyia* (*Chortophila*) betæ, Curtis, being fully treated with illustrations (the maggot being shown on part of what appears a Celery leaf) on page 83 of the Report, infestations being more prevalent in the south than in the north of England.

The attack of the larvæ of the Alder or white-barred clearwing moth is noticed as affecting Alder trees in Wales and ruining them, as we have also noticed in Flintshire over twenty years ago. Garden chafer, May bug, or Rose beetle is recorded as destructive to the foliage of Apple trees in 1892; also the larvæ of the Apple sawfly, which, though a common infestation, cause the young Apples to fall in shoals, the same thing occurring to Crabs. Asparagus beetle receives a generous share of attention; Cabbage aphid, Onion fly, Pea weevils, and root-knot eelworm in Tomato roots are liberally treated. The latter is stated to cause knots or galls on the roots of Tomato, Cucumber, Potato, Parsnip, Peach, Vine, Lettuce, and many other plants, which may be more or less correct, but the galls are in many cases perfectly innocent of eelworms. Nevertheless, root-knot eelworm (*Heterodera radicola*, Greef.) has proved destructive to the gardener's crops of Cucumbers, Melons, Vegetable Marrows, and Tomatoes, whilst the plantman often finds it destroys his Gardenias at the collar or neck by an abnormal gouty excrescence. Miss Ormerod mentions a Tomato grower that has suffered losses to the extent of tons of fruit. An excellent illustration is given of Tomato roots galled by attack of *Heterodera radicola* (two renderings of the specific name being given, the latter being Müller's). It is also called *Anguillula radicola*.

Mention is made of Lettuce as a trap for eelworms, it being sown as early in spring as possible, so that Tomato growers may sow the Tomato beds or borders with Lettuce in advance of planting the Tomato plants, and clear the Lettuce away with the eelworms, of course, and thus save the Tomato plants, otherwise no cure is known but "starving out" the

pests. How that is to be done, if they live on so many different hosts, is not made so clear as is desirable. The only safeguard we know is to expose the soil in which the plants are to be grown to a heat of not less than  $212^{\circ}$  so as to destroy the eelworms. In using trap plants care must be to remove all the roots on which the little knobs appear, and that means removing the uninfected as well as the attacked, for nodules are natural to some plants and never absent from them, in fact it is doubtful if they could exist without them. Growers, therefore, must learn the history of the microscopic objects so as to be able to distinguish infested soil from that free from parasitic germs, for the remedies are worse than the disease, as guidance by galled roots would mean the destruction of healthy as well as unhealthy plants. Trapping, also, is more likely to spread than limit the disease by supplying food upon which the enemy thrives, for who can pull up a Lettuce plant and not leave the major part of the little knobs on the roots behind? Gas lime is the best cure for eelworm, but it can only be applied to bare soil, and some time must elapse before the ground can be sown or planted again. Still it is an excellent disinfectant of soil from which plants have been removed that were infested with eelworm. So, also, is sulphate of iron, indeed all sulphates, but there is nothing so effective as a change of soil and crop. Tomato growers should not use the same soil year after year, but bring in fresh, free from eelworm infection, and this is what many of them do.

Black Currant gall mite appears to have found its master in Paris green, but how this can reach the insects in the galls is unexplained. Facts, however, are preferable to theory; yet it would be interesting to know for certain when the mites are likely to be killed by caustic lime—that is, when the mites are on the ground, and what they do there. These being seen in such hosts as we sometimes have represented as being present at the base of the bushes and on the scales of the buds passes our understanding, for though microscopic objects may be visible to the naked eye in the aggregate or in heaps as mildew appears like white dust or meal, it requires a straining of the imagination to see them individually with the best of pocket lens. Of course, the arsenic or the copper of Paris green may be absorbed by the plants in such quantity that their juices may kill the mites (which is doubtful), for it is certain it cannot otherwise affect them through the gall.

The bearing of these reports is not only to collate facts respecting the diseases of crops, but to interest all cultivators in matters essential to the most profitable cultures, leading them from the uncertainties and disadvantages of foul land to the known and substantial beneficence of clean crops. No less than thirty-six attacks of injurious insects, eelworms, and fungi are treated historically and scientifically, in a popular and exhaustive manner, with illustrations of infestations and the insects in the perfect or larval state causing them, besides the four beautiful full page photogravures of the slime fungus infesting Turnips and Cabbages, and Tomato plant attacked by eelworm, the whole embodying a record of diseases prevalent throughout this country in 1892, with methods for their prevention and remedy. It may be said that the sixteenth report surpasses in excellence of elucidation and information previous reports, which is saying a great deal, but not too much, for they get larger and better each year, and place all cultivators of farms, forests, and gardens under great obligations to the gifted author. We cordially recommend the sixteenth report as deserving of the careful perusal of all interested (and who is not?) in the cultivation of crops.—G. ABBEY.

### THE WAKEFIELD PAXTON SOCIETY.

THE annual dinner of the members of this Association was held in the Society's large room on the 12th inst., and was in all respects highly successful. The room was crowded, and the adjoining library had to be utilised as a means of affording food for the body as well as the mind. The esteemed President of the Society, Major Taylor, J.P., presided, and was supported by the Mayor of the city (C. J. S. Booth, Esq.), Mr. Alderman Milnes, and other public officials. The repast provided by Mr. Oakes of the Saw Hotel was an excellent one, the speeches delivered were much appreciated, and the beautiful singing of members of the choral union was greatly enjoyed.

The Wakefield Paxton Society has been established sixteen years, and consists of amateurs and gardeners, the former predominating. It is admirably managed, and its position as an active and useful educational organisation is generally recognised. If it continues increasing it will soon have 300 members. Forty-six meetings were held during the past year, all of an educational character, and the whole expenses were met by an outlay of a little over £30. An excellent library has been formed, and includes, as all such libraries should, valuable works of reference on gardening, national history, and scientific subjects. This is better than frittering money away on cheap manuals that members of such institutions can obtain for themselves. An extract from the annual report will indicate the character of the excellent Society and its work.

The Committee, in presenting this the sixteenth annual report, are pleased at being able to congratulate the members on the highly satisfactory position of the Society at the present time. The work of the past year has been of a distinctly progressive and beneficial character.

Taking in order of importance the weekly meetings, these have been well attended, the average attendance at each meeting being forty-one. The subjects treated of have been of a varied character, gardening and horticultural topics taking the lead, lectures on various scientific subjects, travels and other questions of general knowledge agreeably relieving the

programme of essays issued from time to time. Forty-six meetings have been held during the past year, and at forty of these a lecture or essay has been delivered.

We are pleased to note that an arrangement was made at the commencement of the winter session for the delivery of a series of lectures on "The Elementary Principles of Botany," by some of the members, who take a deep interest in the pursuit of this science. We are glad to report that these lectures have been highly appreciated by both classes of members—amateurs and professional gardeners—being recognised by them as a means of conveying and explaining the most important facts relating to the structure and functions of plants, which knowledge enables anyone to better perform and understand the practical operations of gardening. The discussions at all the meetings have invariably been of a highly interesting and intelligent character, and have been the medium for eliciting valuable information. The Committee desire to express their best thanks to members of societies in other towns for their assistance in the delivery of essays.

The main object of the Society being the promotion and diffusion of knowledge on horticultural and cognate subjects, the Committee feel that their efforts in this direction have been amply rewarded by the results named, and so long as this most important branch of the Society's work is carried on in the same vigorous manner which has been the case during the past year, the members need not fear for the stability and welfare of the Society, which has been built up on this basis being maintained.

The members' roll now stands at 286, being a net increase for the year of eighteen; twenty-nine new members have been made and eleven struck off the list, seven by reason of death and four by removal from the city.

In last year's report the offer of the *Journal of Horticulture* was referred to, and it was then announced that the competition for an essay on "Education on Gardening," would be open to all the Yorkshire societies. This has taken place and we are pleased to note that a silver medal was awarded to Mr. Thomas Garnett for his essay on the subject named. A second medal was also awarded to Mr. Smith of Sheffield, both essays being considered by the judges as excellent. We congratulate both gentlemen on their success, and trust the essays, which have been published, have proved a benefit to the gardening profession.

The medals referred to were presented in appropriate terms by the President, and the recipients in acknowledging them were much applauded. Mr. J. Wright proposed the toast of the Paxton Society. The chief speakers during the evening were the President, the Mayor, and Messrs. J. Haigh (Sheffield), C. D. Watson, G. W. Fallas (Hon. Sec.), Herbert Chapman and Alderman Milnes. The proceedings were most enjoyable throughout, and the Paxtonians are looking hopefully forward to the future.

### THE CONIFERS AT DROPMORE.

[A paper by Mr. A. CECIL BARTLETT, Foreman at Dropmore Gardens, read before the Devon and Exeter Gardeners' Mutual Improvement Association on April 5th.]

THE planting of the Conifers at Dropmore was commenced early in the present century by Lord Grenville, but the first Conifer planted by him was a *Cedrus Libani* in 1792, and is now a splendid specimen 104 feet high, with a girth of 12 feet 9 inches at 3 feet from the ground. Contrary to general expectation the soil in which the trees are planted is not very good. It is chiefly light and gravelly, the substratum gravel and sand, into which the trees root freely. And unlike many pinetums where the trees are grouped mostly in a confined area, here they are scattered about, some having the protection of forest trees, and planted without any formality or design. Some of the best trees have been periodically assisted by top-dressings of clayey loam, old potting soil, and any refuse likely to decay.

*Araucaria imbricata* (the Chili Pine) has been planted largely. The finest specimen is over 70 feet in height—a noble tree, with branches sweeping the ground on all sides; it has a spread of branches 38 feet in diameter, and in shape is a perfect cone. It is a male tree, producing numbers of pollen-bearing catkins every year. This tree has an ideal position—sheltered, yet not crowded, planted on a knoll about 60 feet from the edge of a lake. The spot on which the tree is planted was once a gravel pit, which was filled up when the lake close by was made; therefore it has the benefit of a good depth of soil and perfect drainage. The tree was bought at a sale in the Chiswick Gardens in 1829 and planted in 1830. Amongst the *Araucarias* planted at Dropmore the majority of those bearing pollen catkins grow more vigorously than those producing fertile cones. In a group planted 1842 the largest is a male tree over 50 feet in height, fully 12 feet taller than the female trees, one of which bore thirty fertile cones in 1891.

Noteworthy at Dropmore is the Cedar avenue, composed of 140 trees of *Cedrus Libani*, planted some eighty years ago, and now averaging over 85 feet in height and  $7\frac{1}{2}$  feet in girth, and, although planted 50 feet apart, and 40 feet in the lines, the effect would have been greater now if the trees had been allowed 20 feet more room each way. Viewed from the carriage drive from the Taplow entrance the effect is grand and imposing. *Cedrus deodara*, the Himalayan Cedar, thrives wonderfully well. In fifty-three years one specimen has attained a height of 72 feet, with a girth of 9 feet 9 inches. The largest *C. deodara* was destroyed by lightning in 1881, and was then considered the finest specimen of its kind in the kingdom. The trunk near the ground measured 12 feet 3 inches in circumference, and good boards 38 inches in width were cut from it. *Cedrus Libani argentea* makes a beautiful tree; when the sun is shining upon it it bears a strong resemblance to *C. atlantica*, so much so that it is difficult to distinguish any great difference between the two species, except that the points of the branches of *C. L. argentea* are not so erect as those of *C. atlantica*.

The finest tree of *C. atlantica* was planted in 1843, and is 64 feet high and 5 feet 10 inches in girth, well clothed, and of splendid shape. *C. Libani argentea* measures 84 feet in height, with a girth of 10 feet.

The genus *Abies*, almost without exception, thrives remarkably well, and the majority of them are branched to the ground. The finest of this class is a tree of *Abies Douglassi*, the Douglas Fir, which was planted in 1830, and is now over 120 feet in height, and has a girth of 11 feet 9 inches, and branches sweep the ground at a diameter of 64 feet. The seed from which this tree was raised was sent to Lord Grenville by the Royal Horticultural Society in 1827, and although snowstorms in the winter of 1880-81 had broken several of the upper branches, the specimen is fast outgrowing the damage it sustained. It is the parent of several trees planted in different parts of the estate; and one, which was planted 1843 is 78 feet high, and has a girth of 8 feet 2 inches, and a spread of 39 feet; a perfectly formed specimen.

Before going further I may state that the "girths" of all trees mentioned in this paper have been taken at 3 feet from the ground. *Abies Albertiana*, Prince Albert's Fir, planted in 1861, is now over 60 feet in height, girth 5 feet 3 inches; a beautiful specimen, its branches touch the ground, and it has a spread of 40 feet in diameter. *A. amabilis*, planted in 1847; height 48 feet 6 inches, girth 6 feet 9 inches. *A. Brunoniana*, the Indian Hemlock Fir, planted in 1847; height 42 feet, circumference of branches at base 134 feet. *A. cephalonica*, the Greek Silver Fir, planted in 1843; height 71 feet, girth 8 feet 7 inches, a very fine tree. *A. concolor*, planted in 1857; height 51 feet, girth 5 feet 9 inches; a very good specimen; was bought at Chelsea when 3 inches high for 3 guineas. *Abies grandis*, the tall Silver Fir, planted in 1861; height 64 feet, girth 6 feet 6 inches, spread of branches 55 feet. A very handsome tree, has leaves of a rich green, the branches touch the ground on all sides. *A. Menziesi*, Menzies' Fir, planted in 1841; height 73 feet, girth 7 feet 3 inches of clean growth; very symmetrical. *A. nobilis*, the Noble Fir, planted in 1835; height 71 feet, girth 7 feet 9 inches. A beautiful, well clothed, branched to the ground. *A. pectinata*, the common Silver Fir; height 94 feet, girth 8 feet 6 inches. *A. pindrow*, the Indian Silver Fir; rarely attains any height in this country, it begins to grow early in the spring, and is usually nipped by the frosts later in the season. *A. pinsapo*, the Spanish Silver Fir, planted in 1843; height 65 feet, girth 6 feet 10 inches. *A. Smithiana*, the Indian Spruce, planted in 1843; height 61 feet, girth 7 feet, spread of branches 38 feet in diameter. A splendid tree, branches hanging on the ground. *A. taxifolia*, planted in 1841; a well grown tree about 60 feet in height.

According to the "Genus Pinus," a work by Lambert, published in 1832, the Dropmore collection of Pines was then the finest and most complete in the kingdom. The majority of that collection have gone the way of all trees, but there are a few old veterans left, and they look grand and noble in their old age, more especially on a bright day in early spring, when the sun brightens up the red tints of the bark, which is relieved by the green of the leaves above.

Amongst the Pinuses are *Pinus Benthamiana*, a variety of *P. ponderosa*, planted in 1843; height 56 feet, girth 6 feet 3 inches, one of the most strikingly handsome trees of the genus, its long leaves are of a most beautiful green. *P. excelsa*, the Himalayan Pine, planted in 1845; a fine tree, well clothed, growing healthily and bearing numbers of cones annually. *P. insignis*, the "Remarkable" Pine, planted in 1839, height 90 feet, girth 11 feet 2 inches, usually considered very tender and delicate, but here it grows robustly and is rarely injured by frosts. *P. Jeffreyi*, Jeffrey's Pine, height 47 feet, girth 4 feet 6 inches. *P. escarene*, a variety of *P. pinaster*, planted in 1841, raised from seed produced here from a tree presented to Lord Grenville by Lord Aberdeen. *P. Laricio*, the Corsican Pine, planted in 1829, height 96 feet, girth 9 feet 9 inches, a grand tree, a giant amongst Pines. *P. Lambertiana*, the Sugar Pine, planted in 1843, height 71 feet, girth 8 feet 9 inches, a splendid specimen. *P. ponderosa*, the western Pitch Pine, planted in 1829, height 85 feet, girth 8 feet 9 inches, a good timber tree with a clean straight bole. *P. Pallasiana*, the Crimean Pine, height 96 feet, girth 11 feet. *P. Pyrenaica*, the Pyrenean Pine, height 86 feet, girth 9 feet. *P. Strobis*, the Weymouth Pine, a very large tree. *P. Strobis alba*, a variety of *P. Strobis*, but with more silvery leaves, very brittle branches.

Another noteworthy specimen is *Cryptomeria Lobbi*, planted in 1843, which has attained a height 53 feet, and perfectly straight. Of *Cryptomeria japonica*, the Japanese Cedar, there are also some fine specimens of good shape and with branches to the ground. *Cunninghamia sinensis*, no date, height 39 feet, girth 4 feet 10 inches, branches within 5 feet of the ground, growing well, but some of the lower branches die annually. *Thuja gigantea*, Lobb's Arbor Vitæ, height 62 feet, girth 6 feet 6 inches, a very fine specimen. *Sequoia sempervirens*, the Californian Redwood Tree, planted in 1845, has made a very fine tree, fully 80 feet in height and branches hanging on the ground. *Taxodium distichum*, the Distichous Cypress, grows freely near the water's edge. *Wellingtonia gigantea*, the Mammoth Tree, planted in 1857, height 67 feet, girth 11 feet 3 inches, and another specimen planted in 1862, 62 feet in height, girth 12 feet; taking age into consideration these are two very fine trees, the branches touch the ground and the trees are growing robustly.

The collection also includes good sized healthy trees of *Abies canadensis* (the Hemlock Spruce), *A. nigra* (the Black Spruce), *A. carpatica*, *A. J-zensis* (the Jesso Fir), and *A. Nordmanniana* (Nordmann's Fir). Some specimens of *Cupressus Goveniana* (Gowen's Cypress), are strikingly beautiful now, covered with numerous yellow male catkins,

bearing immense quantities of pollen, which gives the trees a distinctly decorative appearance.

*Cupressus Lawsoniana* (Lawson's Cypress), *C. thurifera*, *C. funebris* (the Funereal Cypress), *C. macrocarpa* (the Large-fruited Cypress), *Cephalotaxus Fortunei*, *Glyptostrobus heterophylla* (the Chinese Water Pine), *Pinus monticola*, *P. montana* (the Mountain Pine), *P. Inops* (the Scrub Pine), *P. pungens* (the Table Mountain Pine), *P. pinaster* (the Cluster Pine), *P. ncoza*; *Retinospora pisifera* (the Pea-fruited *Retinospora*), a very good specimen; *Taxus fastigiata* (the Irish Yew), *T. Dovastonei* (the Westfelton Yew), and many other trees too numerous to mention are also well represented.

Young trees have been planted from time to time, and the majority are growing strongly, notably some specimens of *Thuia dolabrata*, *T. dolabrata variegata*, *Retinospora squarrosa*, *Thuia gigantea*, *Juniperus japonica alba*, *Pinus pinea*, all planted in 1872. Planted at a more recent date are *Abies amabilis*, *A. bracteata*, *A. Hookeriana*, *A. orientalis*, *A. polita*, *A. Veitchi*; *Cryptomeria elegans*, *Juniperus drupacea*, *J. virginiana Schottii*; *Retinospora obtusa aurea*, *R. obtusa gracilis*, *R. pisifera aurea*, *R. plumosa aurea*, *R. filifera*; *Thuia occidentalis*, *T. aurea*, *T. filiformis*, *T. Standishi*, and *Sciadopitys verticillata* (the Umbrella Pine).

In concluding this short account of the Dropmore collection of trees I may mention that the largest *Araucaria* is supposed to be the finest in the northern hemisphere, and this opinion is corroborated by Professor Sargent and many other tree enthusiasts that frequently visit the estate, which is always open to visitors on week days.

Tree planting in days gone by was a much more expensive hobby than it is now, as witness the recorded price paid for many here, of which I may instance the following history of one of the *Araucarias* supposed to have been raised from a cutting taken from the original tree in Kew Gardens, and by some means passed into the nursery of the late Mr. Knight, King's Road, Chelsea, now Messrs. J. Veitch & Sons:—"Lord Grenville knowing this sent his gardener to purchase it at any price, and he gave ten guineas for it—a small branch with a few roots." How many employers now would purchase trees at such fancy prices? Gardening has taken another turn, Orchid fanciers being now in power as far as fancy prices are concerned. Let us hope that at no distant date ornamental tree planting will again come to the front, and all the newer introductions find a congenial home in every Devonshire estate and others throughout the country.

## ARUMS.

FOR various forms of church and home decoration in early spring these plants, with their glossy leaves, and broad white spathes, are indispensable, and fortunately they are easily produced. The only point upon which cultivators appear to differ is that of planting out the roots in summer, or keeping them in pots. I favour the former plan, as a decided gain is effected in labour. When the plants are kept in pots they need much water during the hot days of summer, even when partly rested, as is the practice of many persons. Our plants opened their first spathes in December, and have continued to give a supply ever since, culminating in a goodly number at Easter, and we have promise of more for three weeks to come.

Our method of growth is briefly this. Plants now in 10-inch pots are divided mainly into single crowns. Those in 8-inch pots we plant entire; these were the single crowns of last year's planting, and they make the largest specimens for the next season. We thus have plants of various sizes. A border having a western aspect is chosen for the summer quarters, and as the soil is retentive watering is reduced to a minimum. A small quantity of manure is added when digging the ground deeply in the autumn. The plants grow freely, and ample space is provided to prevent the growth becoming weakened by overcrowding.

When potting, towards the end of September, a mixture of strong turfy loam and horse manure is employed, two parts of the former to one of the latter. Shade is provided for a few days after potting, as the roots are reduced to enable us to get them into the desired pots. The plants are stood on the north side of a high wall, and well syringed several times daily. When the roots have fairly taken hold of the new soil stimulants are liberally supplied. Nothing is better than liquid made from cow manure and soot. Such a gross feeder is this *Calla* that it is difficult to give the plants too much water when the drainage is perfect.—E. MOLYNEUX.

## AIDS AND HINDRANCES IN FRUIT CULTURE.

MUCH has been said and written respecting fruit culture and the fruit supply, and a vast amount of useful information has been disseminated through the Press and by Mr. Wright's gold medal prize essay, which should be bought and read by all who desire to make fruit culture profitable. I have found mixed plantations of fruit trees the most satisfactory—viz., Apples, Pears, and Plums, with Gooseberries for picking green, planted in rows at 4 feet apart between the trees, to be cut out or replanted at a greater distance when too thick. The value of mixed plantations was well shown last year in some parts of the country, where Pears and Plums were failures, whilst Apples were a splendid crop, while in other parts where Apples were a poor crop Plums and Pears were plentiful. Gooseberries can almost always be

depended upon for a crop, which fetch a good price picked green if only very early sorts are grown.

Maiden fruit trees are the best to plant where time and money are not expected to yield immediate results, and where it is intended to crop between the trees for a few years. On the other hand, splendidly rooted, strong, healthy bearing trees can be had from nurserymen, either as standards or dwarf bushes, at from 2s. 6d. to 3s. 6l. each, which will return an immediate per cent. on the outlay; but fruit growing, like everything else, is made profitable or otherwise according to the amount of care and practical intelligence which is bestowed upon the trees. The greatest difficulty I have found with the cottagers and farmers in planting fruit trees has been the first cost in purchasing trees. Bush trees are best for cottagers, and now that small holdings and allotments are being multiplied it is to be hoped that nurserymen will encourage amateurs and cottagers to buy well tried sorts of fruits by making the price per dozen of Strawberries, especially the newer varieties, as reasonable as they can. Of late I have often been applied to as to the price per dozen of new varieties of Strawberries in various catalogues, but when they have seen the difference in the price per 100 and per dozen they have exclaimed that nurserymen do not encourage the small grower to purchase new sorts.—JOHN CHINNEY.

## ROYAL HORTICULTURAL SOCIETY.

APRIL 11TH.

SCIENTIFIC COMMITTEE—Present: Dr. M. T. Masters (in the chair); Mr. Blandford, Professor Oliver, Mr. Michael, Mr. Wilson, Dr. Bonavia, Sir J. T. D. Llewelyn, Rev. W. Wilks, Rev. G. Henslow, Hon. Sec.

*Californian Oranges*.—Dr. Bonavia showed samples of this newly imported fruit. They are peculiar in having the rind open above, with a small Orange protruding from the apex. It appears to be an established variety of "carpellary multiplication," though incapable of propagation by seed, as these Oranges are seedless. It is of common occurrence in the variety called "Mellarose"—("Teratology," by Dr. M. T. Masters, p. 134).

*Gentiana acaulis*.—Mr. Wilson exhibited about a dozen flowers of this plant, showing variations in the colours, from lavender to the deepest blue. Mr. Michael remarked that he had noticed very many about 2000 feet above Innsbruck of the pale blue variety, the pink coloured variety being rare. Mr. Wilson's were specimens cultivated at Weybridge and Wisley.

*Oxlip, var.*—Dr. Masters exhibited an umbel of the true Bardfield yellow Oxlip, *P. elatior*, which is rare in Britain; and a red-flowered variety, from a clump originally introduced into his garden together with the former, which has hitherto borne only yellow flowers.

*Grammatophyllum with Spinescent Roots*.—He also showed a specimen of the roots of this Orchid, remarkable for their much-branching character, the longer roots being covered with short spinescent branches half an inch in length. The thicker roots penetrated into decayed vegetable matter, developing absorbent root hairs, confirming the suggestion of Professor Oliver that the peculiar development was an adaptation to a saprophytism. The Secretary suggests that the short spiny lateral roots may be arrested conditions, in consequence of their not having been buried in any nourishing material.

*Acacia Galls*.—Remarkable specimens were received from Baron von Müller from Australia. They were referred to Mr. Blandford for examination.

*Richardia, Monstrous*.—Mr. Sheppard of The Toddington Orchard Company sent a specimen, one leaf of which was white like a true spathe. In another case there was a small supplementary spathe and spadix springing from the axil of a second spathe. Dr. Masters observed that if this could be perpetuated there might be a succession of bloom from the same stalk.

### A VALUABLE ORCHID.

By some it is thought that the days for "fancy" prices for Orchids are numbered amongst the things of the past, but such is not the case. At the Quorn House sale recently a plant of a very fine variety of *Cattleya Mendeli*, with thirty-two pseudo-bulbs, eight of these with sheaths, was sold by Messrs. Protheroe and Morris for the sum of 220 guineas, the purchasers being Messrs. Hugh Low & Co. of Clapton.

### CŒLOGYNE SANDERÆ.

THIS is a charming Orchid, and is quite distinct from the other species of *Cœlogyne*. As will be seen by referring to the illustration (fig. 59), the flowers are small, and are borne on an erect spike. The petals and sepals are creamy white, with a faint tinge

of lemon yellow. The lip is white, with a beautifully fringed margin, orange yellow centre, surrounded with longitudinal ridges of brown hair-like filaments. It is an exceedingly pretty species, and justly merits the first-class certificate awarded it by the Orchid

FIG. 59.—CŒLOGYNE SANDERÆ.

Committee of the Royal Horticultural Society on Tuesday, March 14th, when it was exhibited by Messrs. F. Sander & Co., St. Albans.

### PHALÆNOPSIS SCHILLERIANA VESTALIS.

ALBINO forms of the beautiful *Phalænopsis Schilleriana*, says "The Orchid Review," are excessively rare. The one above named was described by Reichenbach upwards of ten years ago from the collection of Messrs. Hugh Low & Co. of Clapton. A plant was exhibited by them at the meeting of the Royal Horticultural Society held on February 14th last, and was deservedly awarded a first-class certificate. It is said to be the only plant known in England. The flowers are snow white, with the exception of some light brown spots on the inner halves of the lateral sepals, a few yellow-brown ones near the base of the side lobes of the lip, and a yellow crest. It is a chaste and very beautiful form.

The variety *immaculata* differs in having no spots anywhere, the crest alone being pure yellow. There is, however, a faint flush of pale rose sometimes present in the flower. It was described by Reichenbach as long ago as 1875 from the collection of J. T. Barber, Esq., of Spondon, near Derby, having been obtained from an importation made by Messrs. Hugh Low & Co. Another plant flowered in February, 1891, from an importation made by the same firm. They contrast effectively with flowers of the ordinary rosy form.

**EVENTS OF THE WEEK.**—Next week will be a busy one with horticulturists. The Committees of the Royal Horticultural Society meet at the Drill Hall on Tuesday, April 25th, particulars of which are given elsewhere. On the same day, and at the same place, the Exhibition of the National Auricula and Primula Society will take place, whilst the Show of the Manchester Royal Botanic Society opens on that day at Manchester. The second spring Exhibition of the Royal Botanic Society will be held in the Gardens, Regent's Park, on Wednesday, 26th; and the annual dinner of the Royal Gardeners' Orphan Fund takes place in the evening of that day. The Royal National Tulip Society will hold a meeting on Saturday, 22nd, at Manchester, as notified in a paragraph below.

— **THE WEATHER IN LONDON.**—With the exception of a very slight fall of rain on Sunday evening we have again to record another dry week. Monday proved cold and dull however, but Tuesday opened bright and mild, similar weather continuing on Wednesday, and at the time of going to press. Rain is needed in the south.

— **WEATHER IN THE NORTH.**—On the night of the 11th we had 4° of frost, the two succeeding days were bright and cold. The unusual drought gave way on Saturday afternoon, and since then a great deal of rain has fallen. This changed to snow for some time on the forenoon of Sunday, and this morning (18th) is very dull, raw, and cold, with wind in N.E. The effect of the rain on pastures is already apparent.—B. D., *S. Perthshire*.

— **THE ROYAL NATIONAL TULIP SOCIETY.**—The next meeting will be held on Saturday, April 22nd, at the Bull's Head Inn, off Market Place, Manchester, at 3 o'clock in the afternoon, to fix the day of Exhibition, to appoint judges, to revise the schedule if necessary, and to transact any other business. Members who cannot attend are desired to write, stating the date they prefer for the Exhibition, and any further suggestions they make will be fairly considered. Mr. James W. Bentley, Stakehill, Castleton, near Manchester, is the Honorary Secretary.

— **ROYAL HORTICULTURAL SOCIETY.**—We are requested to state that the next meeting of the Royal Horticultural Society on April 25th at the Drill Hall, James Street, Victoria Street, Westminster, promises to be of exceptional interest in every way. Besides Daffodils, Orchids, hardy plants, fruits, &c., the members of the National Auricula and Primula Society will bring their choicest plants, which will be sure to attract universal attention. At 3 P.M. the visitors will have an opportunity of hearing a lecture on "Alpine Plants" by Mons. Henri Correvon of the Jardin d'Acclimatation, Geneva. The lecture on "Chemical Questions Concerning the Soil," by Professor Cheshire, has been postponed until May 9th.

— **THE DODWELL TESTIMONIAL FUND.**—We are glad to learn that the funds for the above testimonial will permit of a handsome sterling silver tea and coffee service being presented to Mr. and Mrs. Dodwell on the occasion of their golden wedding; but as the limits of Mr. Dodwell's house are too small to permit of a large gathering, and Mrs. Dodwell's health not being such as to allow her to venture on having a garden party so early in the season, it has been proposed to send the service to Mr. and Mrs. Dodwell for the 20th, the anniversary of their wedding day, and that the formal presentation, with a salver or any other piece of plate purchased from the balance of funds, shall be made at the annual gathering of the Carnation and Picotee Union in Mr. Dodwell's garden on August 1st. This the Committee hope will enable as many of his friends as possible to take part, and all are invited to be present on that occasion.

— **DULWICH PARK.**—Residents in the district immediately surrounding this beautiful park must recognise the pleasures and benefits it has for them. At the present time many trees are in full bloom, and during the past two or three weeks the beds have been gay with Hyacinths and other spring-blooming plants. The robust health and cleanliness of the whole show how thoroughly fitted is Mr. Moorman for the position which he fills.—F. W. W.

— **HARLESTON HORTICULTURAL SHOW.**—We are requested to say that the Harleston Horticultural Show will be held on Tuesday, July 11th, and not as previously fixed.

— **SUPERINTENDENT OF EPPING FOREST.**—We are informed that Mr. Frank M'Kenzie, third son of the late Major M'Kenzie, has been appointed to succeed his father as the Superintendent of Epping Forest.

— **GARDENING APPOINTMENT.**—After ten and half years' service as gardener to the Rev. W. Elmhirst, of Elmhirst, near Barnsley, Mr Sidney Ballinger has been appointed gardener to T. Fox, Esq., Harbro Hill House, Barnsley.

— **THE WEATHER IN WEST YORKSHIRE.**—Rain fell here (Bingley) on the 15th and 16th inst. Yesterday (17th), and to-day have been mild and warm. Outdoor fruits promise a plentiful return, especially Pears and Cherries.—T. H. B.

— **DEATH OF MR. JOB COLE.**—We regret to hear of the recent death of Mr. Job Cole, of Sutton Coldfield, formerly of the Perry Bar Nurseries. Mr. Cole was at one time an assistant at the Birmingham Botanic Gardens, when Mr. Donald Cameron was the Curator.

— **EARLIER OPENING OF KEW GARDENS.**—An attempt is being made to induce the First Commissioner to reconsider his decision in regard to the earlier opening of Kew Gardens. The Kingston Town Council has appointed a deputation to wait upon Mr. Shaw Lefevre, and other authorities are taking the matter in hand.

— **MR. ALEXANDER RITCHIE,** Kelvin House, South Lambeth Road, and of Steven Bros. & Co., Manufacturers of Hot Water Apparatus, Upper Thames Street, has been appointed by the Lord Chancellor, on the recommendation of the Lord Lieutenant, the Duke of Westminster, a Justice of the Peace for the County of London.

— **FRUIT TREES AT EARL'S COURT.**—Messrs. J. Cheal & Sons, Crawley, are preparing an interesting exhibit at the Gardening and Forestry Exhibition at Earl's Court. This consists of various phases of fruit culture. They will show an orchard, market plantations, and kitchen gardens and walls, and the various methods of planting, pruning, and training of fruit trees.

— **THE NARCISSUS FLY AND AMARYLLIS BULBS.**—Perhaps some of your readers can recommend some means of protecting Amaryllis bulbs from destruction by the Narcissus fly (*Merodon*), which destroys so many Daffodils and Narcissus. I have lost three-fourths of my Amaryllis bulbs this year through it. Although most of them had been soaked in a tub of soot water for hours last autumn the grubs did not seem to suffer.—E. D'OLIER.

— **NEWCASTLE AND DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY.**—The monthly meeting of the members of the above Society was held on Wednesday last in the Wood Memorial Hall, Mr. A. Heslop in the chair. Mr. Geo. Walker of The Cedars, Low Fell, read a very interesting and thoroughly practical paper on Tomatoes, after which was a lengthy discussion. The benevolent scheme was allowed to stand over for further consideration until next meeting. Votes of thanks then terminated the meeting.

— **CARDIFF HORTICULTURAL SOCIETY.**—The fifth annual Exhibition of this Society will be held in the Sophia Gardens, Cardiff, by the permission of the Marquis of Bute, K.T., on August 15th and 16th. A liberal schedule of prize has been prepared, there being no less than 168 classes in all divisions. For twelve stove and greenhouse plants in bloom, distinct varieties, prizes to the value of £12 first, £8 second, and £4 third are offered, and these should bring forth a good competition. Mr. H. Gillet, 66, Woodville Road, Cardiff, is the Secretary.

— **WIDCOMBE INSTITUTE HORTICULTURAL CLUB.**—Last week the members of the Widcombe Institute Horticultural Club held a bulb show and social meeting at the Church Room, when a numerous company accepted invitations. The exhibits were staged in the centre of the hall, and many of the contributions were of exceptional merit. The group of miscellaneous plants lent by Messrs. Cooling & Sons, Bath, was one of the most noteworthy features of the Exhibition, and came in for general admiration. The following certificates were also presented:—For two groups of plants, Mr. T. J. Tate; four Crown Imperials, Mr. H. J. Troutt; five Auriculas, Mr. H. J. Troutt; box of Roses and Pansies, Mr. F. Hooper; and another to Messrs. Cooling & Sons for their collection of flowering plants.

— FROSTS IN WILTS.—On Thursday night, the 13th inst., the thermometer registered 7° of frost, the 14th 9° also, and being followed by early bright sunshine damaged the Plum, Cherry, and Apple blossoms, which are expanded.—G. F., *Trafalgar, Salisbury*.

— A FLOWER SHOW AT THE PEOPLE'S PALACE.—It is reported that preparations are being made to hold a Flower Show at the People's Palace in the East of London on July 13th, 14th, and 15th next. A Committee is being formed to carry out the project, prominent workers including the Marquis of Lorne and Sir Charles Fremantle. A novel attraction will be a representation of a battle of flowers.

— LAVENDER IN AUSTRALIA.—It is stated that Lavender is now extensively cultivated in South Australia for economic purposes. The plant at one time was regarded as a nuisance by the settlers, as their cattle would not eat it. Acting on the advice of Mr. Molineux, Secretary to the Agricultural Bureau of South Australia, a settler has planted a considerable area, and intends to distil the scent from the flowers.

— A GRAFTED PELARGONIUM.—Mr. H. L. Jones records, in the "Botanical Gazette," an example of a graft-hybrid between two different varieties of Pelargoniums, a red and a white. In several successive years the flowers partook of the characters of both parents; some were pure red, and others pure white; others had some of the petals white, others red; while in others again the petals were red mottled with white, or white mottled with red.

— CHIONODOXA TMOLUSI.—Through an error this appears as C. Smolusi on page 290, and in correcting this I may also remark that there appear to be two varieties doing duty under this name. The form in my garden is of finer colour than C. Lucilæ, but it would appear that there is another form of inferior colour to C. Lucilæ, and consequently the merits of C. Tmolusi are not appreciated by some. My opinion of C. Tmolusi is corroborated in a letter I had the other day from one of the keenest growers of bulbous flowers in England. He speaks highly of this variety.—S. ARNOTT.

— ST. BRIDGET ANEMONES.—Mr. James Harris, Blackpill, Swansea, writes:—"In July last year Mr. Pettigrew sent you an account of the St. Bridget Anemones here. This evening (April 13th) I have forwarded you a few blooms and foliage that you may see what they are. The Anemones are charming now, and have been for the last month, and I expect them to keep flowering for another two months. I am still selecting them, and I hope to have them perfect in a season or two, as I have much seed in hand, and now I consider the right time to sow for next year's display." [The Anemones were the best of the kind we have seen. The flowers were magnificent, fresh, varied, and brilliantly coloured.]

— DECIDUOUS MAGNOLIAS.—Although varieties of this section may be much safer as regards protection of their blossoms from frost when growing against a wall, I think there is no comparison between a tree managed in this way and one allowed to grow away at will in a favoured spot in the shrubbery or even isolated on the lawn. Owing to their blossoms expanding before the leaves they are by this means shorn of some of their attractive quality when on a wall. Growing against a wall no plant that flowers before its foliage is developed has the same attraction as an evergreen in bloom, the dull red of the bricks make a hard contrast to the flowers. I agree with Mr. Dunkin (page 276) that the plants when growing in the open are very often destroyed by frost when even in the bud state, but this year they so far have escaped. A tree of the variety *purpurea*, nearly 18 feet high and 15 feet across, growing in an open spot in the shrubbery, is clothed from top to bottom with extremely large blossoms, not one of them touched by adverse weather so far. Although *M. conspicua* is a favoured species I prefer the purple form known as *obovata discolor* or *purpurea*. The deep flush of purple at the outside base of each flower, extending upwards and fading entirely away before the tips are reached, is more attractive, and being rather later in development than *conspicua* it more often escapes the frost than the white blooms. *Soulangeana* is another showy variety, a hybrid between *conspicua* and *obovata*, having the deep purple shade of the latter, but rather more intensified, and having the full rounded flowers of the former. *Soulangeana* is fully a week later in opening its flowers than *purpurea*, and for that reason useful both as giving a longer succession of blossoms and escaping frost as well. In perfume this is perhaps the most pleasing of all.—E. M.

— THE ROYAL GARDENERS' ORPHAN FUND.—At the monthly meeting of the Committee held recently, the Hon. Secretary announced that H.R.H. the Duchess of Albany had permitted her name to be announced as a supporter of the Fund; also that H.R.H. the Duke of York, K.G., had sent a donation of £5. Several other subscriptions were also announced. The annual dinner of the supporters of the Fund takes place at St. James' Hall, Regent Street, on Wednesday, April 26th, when Baron Ferdinand de Rothschild, M.P., will preside.

— THE "BURNING TREE" OF INDIA.—At a recent meeting of the Royal Botanic Society of London, among the Orchids and other plants in flower shown was a specimen of *Laportea gigas*, the "Burning Tree" of India. Both leaves and stems of this plant are covered with stinging hairs after the manner of the common Nettle, but of a far more virulent nature. It is stated that when touched the sensation felt is as of being burnt with red-hot iron, the pain extending over other parts of the body, and lasting for a fortnight. Little or no mark is to be seen on the skin, but, for some time after, should cold water touch the part, the pain returns with all its original intensity.

— WEATHER AT SWANMORE.—We have had forty-three continuous days now without a drop of rain, a fact unprecedented within the memory of the oldest inhabitant at this season of the year. This spell was broken on Sunday (16th) by a light shower, which registered 0.04 inch. On Tuesday (11th) at 6.30 A.M. the thermometer dropped to 27°; on each of the two successive mornings to 29°. With the exception of the earliest expanded Strawberry blossoms, which are blackened, I do not think much harm has been done to the fruit crops, of which there is an abundant promise of all kinds, in this neighbourhood.—E. M.

— THE WEATHER REPORTS.—Mr. J. Easter, Nostell Priory Gardens, Wakefield, writes:—"The monthly reports of the weather by Mr. W. H. Divers of Ketton Hall Gardens, greatly interest me, as they nearly always tally with the register kept here. Perhaps you will allow me to ask Mr. Divers, through the *Journal*, the height his thermometers are from the ground; also if the mean daily minimum is taken from the thermometer hanging the same height as the maximum, and not from the gross minimum? The mean for the month of March here was 45°, that is, taking the maximum and minimum thermometers hanging beside each other. We measured 0.22 of rain only for the month of March."

— AN OLD APRICOT TREE.—In the garden connected with the ruins of the Abbey at Bishop's Waltham is an Apricot tree said to be over 200 years old. The tree is growing against a south-east wall about 9 feet high, and covers a space 40 feet long, and is at the present time carrying a good crop of fruit. The stem near the ground is nearly 18 inches in diameter, while many of the branches are 10 inches, and all of them very rugged in the bark. The tree is rather short of young wood, but on the whole looks healthy. It is presumed the roots are in close touch with a pond not far away. Altogether it is a remarkable specimen, and I am not yet able to determine what the variety is.—E. MOLYNEUX.

— COUNTY COUNCIL HORTICULTURE.—An interesting trial of several old and new sorts of Potatoes is this year being conducted at Bookham, Surrey, through the kind liberality of Mrs. Chrystie, a local resident, who having rented some land for the purpose of forming a garden school for boys of advanced age, also allotted a considerable space for a public Potato trial. This has been placed under the control of the Surrey County Council Technical Education Committee's horticultural instructors, and by them the seed Potatoes were purchased for Mrs. Chrystie and planted on the 13th inst. under the superintendence of Mr. Alexander Dean. Thirty of the best varieties in cultivation were selected from the lists of such popular growers as Messrs. Sutton and Sons, Reading; Jas. Carter & Co., High Holborn; R. Dean, Bedford; and C. Fidler, Reading. The moderate growers are in rows 30 inches apart and all the others 36 inches apart, so that ample space has been allowed. The land is situated in a very open breezy aspect, has hitherto carried field crops, especially corn; it was recently trenched 18 inches in depth, and has been dressed with moss litter manure from London, carefully forked in. Every sort has been labelled, and all are open for inspection by anyone interested in Potatoes. Apart from the interest which will presently attach to such a trial of Potatoes in the county it is hoped, should the disease be in evidence in the summer, to experiment with the now famous anti-fungus mixture, *bouillie bordelaise*, and thus submit in a public way its capacity to check the Potato disease.

— INSTRUCTION IN ORNITHOLOGY.—A daily contemporary observes:—A Government entomologist in one of the colonies suggests a scheme for the instruction of the farmer in ornithology and its relation to agriculture. He proposes farmers should be assisted to form collections of insectivorous birds, labelled with specimens of their nests and eggs, so that they might distinguish between the birds which do service to the agriculturist and those which do harm. The sooner such a system as this is introduced into this country the better; for farmers and those who have the care of orchards and gardens sadly need guidance in the use of the gun. Many friends of farmer and gardener are destroyed on mistaken suspicion.

— PRIMULA ROSEA.—Mr. W. H. Divers, Ketton Hall Gardens, Stamford, observes:—"Although this is undoubtedly hardy as far as the plant itself is concerned, the recent severe frosts have injured the flowers very much here, and they have presented a miserable appearance, quite different to what I anticipated. The abnormal amount of sunshine and dry weather we have had lately have possibly had a little connection with this failure, as none of the Primula family have succeeded so well this spring as usual. If we could only accommodate them with a cool house during the flowering season we might induce the trusses to develop to the utmost perfection."

— HORTICULTURAL CLUB.—The usual monthly dinner and conversation took place at their rooms, in the Hotel Windsor, on Tuesday evening, April 11th. The chair was occupied by Sir J. D. T. Llewellyn, Bart., the Chairman of the Club. There was a good attendance of members, including the Rev. W. Wilks, Rev. T. Handley, Messrs. Geo. Bunyard, E. Cockett, G. Paul, Harrison Weir, H. Selge Leonard, and Dr. Soper. The discussion was upon "Hunting for Alpine Plants," and was opened with a very interesting paper by Mr. H. Selge Leonard, in which, after describing the necessary outfit for anyone engaged in this pursuit, he gave a graphic description of his wanderings in the Dolomite region of the Southern Tyrol and in the Engadine, which he regarded as two of the richest fields of the Alpine flora in Europe, presenting, as they did, that of the granitic and calcareous formation. He showed how in the Dolomite region, especially where the two formations ran side by side, how completely distinct were the plants found on each. With regard to cultivation, he explained some of the difficulties attending it, owing not only to the various requirements of the plants, but also to the varying character of our winters, warm and sunny days being often succeeded by severe frosts and snow, while in the alpine districts the plants were covered with snow throughout the winter, which kept them warm and dry until the frost broke up in the spring. An interesting discussion took place, in which most of the members joined. A cordial vote of thanks was awarded to Mr. Leonard, on the proposition of the Chairman. The Secretary announced that a special dinner would take place on the 25th inst., to do honour to M. Henri Correvon, of Geneva.

— SPRAYING FRUIT TREES.—On Saturday, the 15th inst., the Stott Co. were invited to give an exhibition of their appliances for the prevention and destruction of insect and other pests by some members of the Evesham Fruit Growers' Association. The time fixed was 10 A.M., in the orchard of Joseph Martin, Esq., ex-Mayor of Evesham. Numerous fruit growers were present from Toddington, Evesham, and Pershore, including Messrs. Martin, Wise, Chichester, Field, Hooper, Brodie, Bullough, Gregory, Pollard, King, Clarke, and Gunnal. All the varied appliances and insecticides of the Company were experimented with. Mr. Stott, for the first time, brought out a 30-gallon engine. This engine is filled with a patent quadruple acting wing pump. Two patent insecticide distributors were fixed on the handles of the pump, and from each distributor a length of hose pipe being attached, and the new adjustable spray being used. The distributors being charged with killmright, various bushes and trees were sprayed with the solution given off. The result was everything that could be desired, caterpillars, aphids, and red spider being quickly destroyed. The working arrangements of the pump were fully explained, and it was shown that it is almost impossible to become choked with sand or other sediment. The patent syringe was next charged and used on black fly, the result instant death. This being an informal meeting of the fruit growers of the district, the results were so satisfactory that it was decided to invite the members to meet at 11.30 on Saturday next at Lord Sudeley's, Toddington. Mr. Stott expressed his thanks, and remarked he should only be too pleased to give a further demonstration.

— ALLOTMENTS IN ISLINGTON.—A short time since we announced that an effort was being made to ensure allotments for working men in Islington, and we now learn that "the West Islington Allotment Gardens Association" held a meeting recently at the Drovers' Hall, Metropolitan Cattle Market. The chair was taken by Mr. T. Lough, M.P. It was proposed that the Association should consist of the Trustees and other officers, the allottees, and such honorary members as might be elected by the Committee. The charge for allotments will be from 5s. to 10s. a year.

— VIOLA MANAGEMENT.—I grow a goodly number of Violas for summer bedding. Where many persons make a mistake in their culture is in selecting the wrong cuttings. Those springing direct from the base are the best; these taken off from 1 to 2 inches long the first week in October, dibbled thickly into boxes of sandy soil, and wintered in cold frames, root readily. The second week in March a temporary frame is made up with turf, and the plants put out in rather light sandy soil with a base of Mushroom-bed refuse 2 inches thick. The roots run freely into this, and the plants are removed to the open ground without receiving any check to free growth.—E. M.

— VINES AND VINE STOCKS.—Apart from the influence that one particular stock has over another variety in the growth and finish of the fruit, grafting affords opportunities for introducing other kinds into an established vinery. It is generally acknowledged that it is a bad plan to plant young canes in an old border. Even if such Vines succeeded, they need more time to carry an equal crop of fruit than canes that are the result of grafting. Striking instances have occurred showing the effect of grafting upon certain varieties. I remember seeing two Vines of Madresfield Court that were grafted on Black Hamburgh stocks; the berries in both cases cracked very badly, while another Vine of the same variety growing on its own roots in the same border was never known to have a split berry.—E. M.

— THE YOUNG GARDENERS OF FALKIRK.—I was very much interested with the remarks of "A. G." (page 292) concerning the young gardeners of Falkirk and district in petitioning their employers for a holiday on Saturday afternoon. It is most gratifying that some of the gentlemen conceded to their wish. All the men employed on this estate cease work at 1 P.M. on Saturdays. They have enjoyed this privilege for about two years now; it was the wish of my employer. I can assure "A. G.," or the head gardener mentioned, the arrangement works well, and I find I have quite as much work done now as I did when the men worked all day on Saturday. My young men do not leave me to do the work on Saturday afternoons; they each take their turn the same as on Sundays. I am very pleased to see the young men have proposed to form a gardeners' mutual improvement society.—FRED. J. THORNE, *Sunningdale Park*.

— GREEN VEGETABLES.—There can be no doubt but that the long spell of dry weather has seriously checked the development of autumn-planted Cabbages, and whilst many plants have been induced to bolt off to flower, others have remained almost stationary. We may expect to find all forms of green stuffs, and Cabbages especially, somewhat scarce and dear shortly. But the exceeding value of some of the coarser Kales has been well demonstrated recently, and those who had Dutch Curled, Cottagers', and Hundred-headed Kales, also tall Sprouting Broccoli, have derived great benefit from them. Whilst so many of the White Broccolis were killed by the hard weather early in the winter, Sprouting Broccoli has stood very well, and when gathered in a young state it is a very delicious vegetable. Turnip tops are now pretty well over, and even these have been far from plentiful. A late sowing, made specially to produce tops, proved to be of much greater use than did earlier ones that produced good bulbs, as these suffered severely in the winter. If it were generally the practice to raise a few hundreds of hard small Swede Turnips, store them during midwinter, and plant them up thickly early in March they would give a most valuable addition to our commonly scant green vegetables at this time of the year. The discovery that Round Flanders Spinach sown in the autumn is far hardier, and gives far better results in leafage, than the Prickly-seeded variety during the winter should help to make Spinach culture for the winter much more popular. Those who have of Cabbages either Ellam's Early, Matchless, or some other of the early small-headed varieties have much to be grateful for, as these precocious sorts are of the greatest value for this time of the year.—A. D.

— WINTER CHEER CARNATION.—This is without doubt a great acquisition. The habit of the plant is much more robust than Miss Jolliffe and the older varieties, and this is so noticeable that when Mr. Veitch first showed it to me in 1891 I ordered a good stock of it at once. I have been amply repaid by the way it has succeeded here and the great admiration it has called forth from all who have seen it. The flowers are large and of a brilliant scarlet colour, and are produced abundantly

#### AZALEA ANTHONY KOSTER.

WITHOUT doubt one of the most beautiful and striking exhibits at the meeting of the R.H.S. on April 11th was the grand Azalea shown under the above name by Messrs. Lane & Son, Berkhamstead, and which is represented by fig. 60. The trusses of bloom are enormous, and the individual flowers almost equal in size to the best Clivias, the colour

FIG. 60.—AZALEA ANTHONY KOSTER.

during the winter months with very little fire heat; in fact it promises to be quite hardy, as two plants which I put out last autumn have passed through the winter quite safely without any protection, which shows its good constitution. These were dwarf, strong plants, and of course I do not imagine the older and taller specimens are so hardy; but if judiciously managed it appears likely to be a useful addition to the border Carnations also, as we have very few good scarlets worth cultivating.—W. H. DIVERS, *Ketton Hall Gardens, Stamford.*

being clear yellow suffused with orange. Several small plants were arranged in a large basket, and all were completely smothered in flowers. The first-class certificate, which was awarded fitly, conveyed the general impression of this magnificent variety.

It is the result of a cross between *Azalea mollis* and *A. sinensis*, is perfectly hardy, was raised by Messrs. Koster of Boskoop, and sent out last autumn. It is one of the handsomest hardy Azaleas in cultivation, and should be in every collection.

## THE N.C.S. IMBROGLIO AND MEETING.

MR. RICHARD DEAN did not carry out his alleged intention to resign his position as Secretary of the National Chrysanthemum Society at the meeting held last week, but adopted the more prudent course of regretting the action he took in attempting to influence a "certain number" of members in the election of a Chairman of the Floral Committee. We are informed that he read a lengthy statement or "manifesto" with the object of showing how wrong it was for anyone to question his methods, and how rightly he had acted in the interests of the Society. Naturally the Secretary would take that ground, as if all the world were against him it would only show from his view the world's wrongheadedness. In his recent action, which led to the imbroglio, it may be conceded without any reservation that he was animated by the best of motives, but there appears to have only been seventeen persons in an assembly of fifty or sixty who could publicly sanction the course he pursued. It was a partisan course, or the appeal he issued would have been to all the members and not to a selected number only.

As a private member he may have the right to canvas for votes in a "private" manner, but in the case in question the canvas was official on the face of it, or would be so regarded, as official stationery was used. It was intended to influence the election in favour of a gentleman who was not a member of the Floral Committee, and there cannot be a doubt that it prejudiced another gentleman who was and is a member of that Committee. Mr. Dean's justification is that he did not know this member would be nominated, but then it follows that he did not know he would not. An error in judgment was committed, but not with an intention to offend any individual, still an error all the same; and such mistakes on the part of any secretary, paid or not, could have no other effect than creating dissension in the committee and among the members of any society. But mistakes made through want of thought, or under the impulse of good intentions, are essentially venial, and therefore not of a nature to impel to either resignation or expulsion. The rebuke of the meeting was quite sufficient, and the history of the case may not be without effect in cases of a similar character that may possibly occur elsewhere.

Mr. Dean appears to have a strong aversion to be referred to as the paid Secretary of the N.C.S., and though his remarks on the subject at the meeting did not refer to us, it may be said that when we so described him on a previous occasion we had not the slightest idea that the term was objectionable. We had in mind the fact that on the demise of Mr. Holmes it was decided that his successor should be paid for his services, the amount, we think, being £50 a year. We did not know until quite recently that when Mr. Dean was informed a salary was attached to his office he replied in effect, "Oh, please do not call it salary, but rather allow it for clerical assistance." He has a right to his preference, though at the same time it does not detract from the dignity of gentlemen equal in social status to a Secretary of the National Chrysanthemum Society to be paid for their services—to wit, Her Majesty's Ministers and the Secretaries of the Royal Horticultural and Royal Botanic Societies. Not one of these gentlemen could be respected more than they are now if their emoluments were differently described, except by snobs who are unworthy of notice. Mr. Dean, we presume, takes the money that is allowed and disburses it as he wishes, though he does a great deal of secretarial work himself, as he can do very ably. We did not intend to imply the slightest reproach by our reference, and we are perfectly ready to describe him as Honorary Secretary, if such he be, if that is more agreeable to him, though he will remain in the estimation of most men the same Richard Dean as before—impulsive, zealous, and autocratic, but well-meaning; a keen controversialist, who derives more pleasure from smiting with his keen pen than in having his own conduct impugned under any circumstances whatever; yet as a public man he is entitled to the honour of public criticism.

We hear nothing but praise of the conduct of Mr. Gordon at the meeting. His attitude is described as most befitting to the occasion, and his speech admirable in matter and tone. He would most willingly have supported Mr. Shea as Chairman of the Floral Committee of the N.C.S. under ordinary circumstances, and Mr. Shea would as willingly see Mr. Gordon in that position; but both gentlemen decline the honour now, as might be expected, as did others, Mr. Fowler consenting to occupy the position, and we are pleased to note he was elected with unanimity. We are glad also to note that he brushed aside a proposition for another meeting of a conduct-inquiring order. It was surely not necessary and could lead to nothing substantial. Sober work on sound clear business lines will be better for the Society than contentious "meetings."

The one of which a report is given below will, we hope and believe, strengthen the Society. It gave the death blow to autocracy, and established a strong "opposition"—strong not only in numbers but in administrative ability, and as the members composing it are not less earnest in their desire for the prosperity of the N.C.S. than the active officials are we may expect that mistakes will be reduced to a minimum, and that prudence will be the governing factor in the conduct of affairs.

The Society has attained a splendid position in the floral world, and we regret the disturbing influences that arose within it through admitted indiscretions, intensified, we fear, rather than diminished by the dalliance that was allowed to prevail in connection with them. A national society that is afraid of "exposures" cannot for many years remain worthy of its name. Publicity has done much to raise the N.C.S. to its present position, and we suspect there is small fear of a repetition of the errors of the past; had they been permitted to continue, hidden and unchecked, they would have eaten like a canker worm into the very vitals of the Society; it is worthy of a better fate, and the bright future we hope to see.

A meeting of the General Committee of this Society was held at Anderton's Hotel on Wednesday, the 13th inst., when Mr. E. C. Jukes presided.

The first item of importance in the evening procedure was a communication from Mr. C. E. Shea, in which he referred to the circumstances attendant upon his recent election to the chairmanship of the Floral Committee. He felt quite sure the Secretary, in acting as he did by making a canvas, thought he was doing what was best in the interest of the Society; but Mr. Shea felt it was an error of judgment, and could not therefore accept either the position of member of that Committee or the chairmanship. Considering the services Mr. Gordon had rendered he would suggest that that gentleman should be elected.

Mr. R. Dean then said that early in the year Mr. Ballantine had intimated that business would prevent him attending as frequently as before, and he thought the time had now arrived when a Chairman of the Floral Committee should be appointed as distinct from the Chairman of the General Committee. Mr. Shea was approached with the view of seeing whether he would accept the post, as he was a man unpledged in any way, and quite unconnected with the trade. He was also a desirable man in many other ways, and Mr. Dean was quite unaware that anybody else was likely to be proposed for the post. Under those circumstances he did issue a request marked private to a certain number of the members, first, that they should vote for him as a member of the Committee, and, secondly, as Chairman. Up to the moment Mr. Gordon was nominated he had no suspicion that such was to be the case, and it was only a few minutes previous to the meeting that he heard that Mr. Payne was likely to be proposed; but the latter gentleman expressed his willingness at once to retire in favour of Mr. Shea, whom he considered far better as an independent member and an amateur to occupy the chairmanship. Mr. Dean could not see he had done anything he could regret. He protested against being regarded as a paid Secretary, and regretted such an expression should have been used in the columns of a contemporary, and that in spite of all his efforts no withdrawal had been made.

Mr. Gordon considered the question whether the Secretary was a paid official or not of no great importance, but as a matter of fact he was so advised and quite believed he was. He did not intend to allude to the election of the Floral Committee and Chairman because he was defeated. There was no one he would like to see occupy the position more than Mr. Shea, and at the last meeting he was perfectly satisfied with the result until the meeting was over and he learnt a circular had been sent round to influence the voting. It was a question that affected every member of the Society. If any official used his position to influence members in the matter of election the meetings were simply a farce, and could have but one result—viz., to discredit the proceedings of the Society. He thought the Committee was bound to express an opinion whether such a proceeding was right and proper in the management of the Society. He was not a man to make disturbances or create a want of harmony, and did not want it to be regarded as a personal matter; but he had a duty to perform to the members who had voted for him. He objected to proceedings that brought his name and that of his friend Mr. Shea into publicity in the papers in such a way. It was for the Committee to decide whether they would support such proceedings. At present it appeared the Chairman and Secretary were alone responsible, but immediately the Committee expressed their approval they assumed the responsibility. It was not for any officer to influence elections—(loud cheers)—and all that was wanted was for the proceedings to be carried out in a straightforward manner. He would move "that the Committee desire to place on record its disapproval of the action of the Secretary in writing to several of its members with the view to influencing their votes in favour of one of the candidates on the occasion of the election of the Floral Committee on March 6th."

Mr. Rundle thought the whole of the Committee should deprecate the action. It was an endeavour to influence the Committee. He had not received a circular. He thought the Committee should consider the advisability of having a paid Secretary, and thus stop all squabbling. He thought the action would cause a loss of confidence, both by the general public and exhibitors at the Floral Committee.

Mr. Bevan presumed the Secretary acted in his private capacity—any other member might have done so. Other names might have been proposed but for the circular. He thought they ought not to go outside the Committee for a Chairman.

Mr. Witty could not do otherwise than support the motion, and was very sorry Mr. Dean took such an injudicious step. Would it not have been better to leave the election in the hands of the Floral Committee themselves?

Mr. Addison criticised very fully the Secretary's statement, and supported Mr. Gordon's motion. He considered the Secretary a paid officer, no matter in what light the payment for clerical assistance was

looked at. When Mr. Holmes died the members would remember the Committee came to the resolution to pay for the secretarial services, and the word salary was used. Mr. Dean objected at that time to that word being used, and asked that it might be called clerical assistance. Mr. Addison continuing said unless Mr. Shea was elected a member of the Floral Committee first he could not be elected the Chairman. The Secretary knew this, hence the circular.

Mr. W. H. Fowler felt sorry to have to speak on the subject, for Mr. Dean had committed an error of judgment, and he must support the motion. He thought he was not a paid official. Many honorary secretaries were allowed clerical assistance, and properly so. It was very unfortunate, for the gentleman elected was a most excellent choice, and the Society would have been fortunate in having him. He must vote for the resolution, because what had been done was not calculated to inspire confidence.

Several members admitted receiving the circulars, but had not been influenced by them.

Mr. Burridge wanted to pour oil on troubled waters. He thought if Mr. Dean admitted the error the motion might be withdrawn. The Chairman felt so too. He was sure Mr. Dean acted from the best of motives. If Mr. Dean would admit the error he thought the matter might be settled. He had worked most nobly in the past, and had served the interests of the Society, doing an immense amount of work, such as a paid Secretary could not be expected to do for very much more than was allowed Mr. Dean. If they drove Mr. Dean to resignation, and they must consider the effect of the motion if carried, it would be a more serious matter than some of them would think. He protested most emphatically against him being considered a paid Secretary. The future he thought hung in the balance. If matters could be smoothed over, and they did not pass a vote of censure it would be best.

Mr. Gordon replied, and would have been pleased to withdraw the motion if he felt he could do so in justice to the Society. He thought it was a time when the Committee should express its opinion. He was prepared to abide by the decision of the Committee, but to withdraw it would be wanting in his duty.

The motion was then put, there being fourteen in favour and seven-teen against. There must have been nearly as many members who abstained from voting.

Mr. Dean then rose, and said he had no hesitation in saying that he regretted the action. He fully believed he was doing the best for the Society, and if that admission would tend to allay matters he would be only too pleased. He hoped Mr. Gordon would allow himself to be nominated for the post, but that gentleman thought it would not be consulting the best interests of the Society if he did. Several other names were proposed, but they declined. Mr. W. H. Fowler, however, was elected without contest.

Two vacancies having occurred on the General Committee, Mr. Hy. Cannell and Mr. E. Molyneux were elected.

Mr. Jukes protested against being charged with discreditable proceedings, as was lately the case. Everything he had done had been for the best, and he was not ashamed of anything he had done. He might have made mistakes, as who had not, but he distinctly denied being associated in any way with discreditable proceedings.

Mr. R. Ballantine, who came in at a late hour, concurred in Mr. Jukes' remarks. He would be glad to meet the members and lay his conduct in their hands.

Mr. Fowler thought that the calling of any meeting for such a purpose was unnecessary. Anyone who had a grievance against the officials could have attended the annual meeting. As they did not, he could only assume that the majority were perfectly content.

The Chairman said, in reply, that if the members thought the officers had acted unworthily he was quite prepared to place his resignation in their hands. He thought no member ought to take such a mode of expressing his views as Mr. Trinder had done recently.

#### JUDGING CUT BLOOMS.

"SADOC" asks me at page 298 if I have ever awarded *Refulgens* the premier prize when Lord Alcester is competing in prime condition. If he will refer to my last (page 278) he will see clearly what I say about *Refulgens* is not in connection with awarding premier bloom prizes. It reads thus: "But an exhibitor who tastefully arranges his colours and also includes difficult varieties like *Refulgens*, giving his stand a more pleasing and fresh appearance, should have a point for this over one that stages too many all of one colour." This has nothing to do with the question he puts to me, but I will answer it. I have not, and I fancy no one else has either, if Lord Alcester or some other of the Queen family were competing in good condition. But where *Refulgens* tells is in a stand of twenty-four distinct varieties when in first class condition. Most exhibitors would be pleased to be able to include it in a twenty-four stand, for we have not yet even twenty-four varieties of the size and quality of Lord Alcester, and the other a colour we are short of among incurves, having too many light shades.

"Sadoc" will find plenty of judges who, before they will award a premier prize to a bloom, will first lift it out and compare it with some others who may be half a point behind; but I would not like to condemn such men as not competent to award prizes. Can he say he has not adopted the practice himself? If all judges are not just of "Sadoc's" opinion of what he considers the proper way to judge cut blooms, he should not condemn them, or he alone might be left to do all the work. I have seen the most experienced judges at several of our large shows prefer to remove the stands and judge them side by side instead of

measuring the comparison a long distance away, and often in an indifferent light, where it is difficult at times to see the slight shades of colour in the different varieties.—J. LAMBERT, *Powis Castle Gardens*.

#### OBJECTIONABLE VARIETIES.

It has been a mystery to me why exhibitors waste valuable time in cultivating some *Chrysanthemums* which I regard as useless, now there are such a number of superior varieties available. I am not now alluding to collections where the largest classes are filled by competitors, but I specially refer to those cultivators who cannot from their convenience ever hope to compete in classes where no less than at least thirty-six varieties of Japanese kinds are required. Such exhibitors confine themselves to classes of, say, twelve or eighteen kinds, but who at the same time include so many that I regard as being worthless, or nearly so, as exhibition flowers. Even the largest exhibitors have no occasion to rely on some of the sorts met with now that the influx of superior varieties is so large. In competition these inferior kinds lose points, even if the blooms are large and well developed, as compared with those more beautiful and less easy to cultivate.

I do not think growers as a rule pay sufficient attention to those varieties that are acknowledged to be difficult to present in the best possible form. It seems natural that these should be discarded when so many others much easier to grow are obtainable. Take, for instance, *Boule d'Or*, *Etoile de Lyon*, or *Mrs. Alpheus Hardy*. Neither of these can be regarded as being of easy production. True the second named is numerously staged, but not always in good condition. If varieties like the one in question were more often shown as it ought to be we should not hear nearly so much complaining about the large unsatisfactory blooms monopolising the attention of cultivators at the expense of those more beautiful and less cultivated. In competition it would undoubtedly "pay" the exhibitor to conquer the peculiarities in culture of some sorts so as to present these in faultless condition as compared with the poor examples so often met with at shows. Now that English cultivators have taken to hybridising the flowers and saving their own seed, there is really no reason why those that have nothing to recommend them after a whole season's labour has been spent upon them.

Much of the retention of varieties that are useless is owing to prejudice against innovations that needs overcoming. Varieties like *Mrs. Irving Clarke*, *Album striatum*, *Ada Spaulding*, *Baltimoreau*, *Baron de Prailly*, *Bronze Dragon*, *Dormillon*, *Comtesse de Beauregard*, *M. Burnet*, *Fair Maid of Guernsey*, *Meg Merrilies*, *Ralph Brocklebank*, *James Salter*, *Frederic Marrouch*, *M. J. M. Pigmy*, *Maggie Mitchell*, *W. G. Drover*, *Lady Lawrence*, *Madame C. Audiguier*, *M. Tarin*, *Bertier Rendatler*, *Mr. H. Cannell*, *Mrs. E. W. Clarke*, *Peter the Great*, *Soleil Levant*, *Stanstead Surprise*, *Mdlle. Paul Dutour*, and *Elaine* amongst Japanese; and *Lady Talfourd*, *Golden Beverley*, *Beverley*, *Lady Slade*, *White Globe*, *Fingal*, *Pink Perfection*, *Guernsey Nugget*, *Faust*, *Prince of Wales*, *Lord Derby*, *Mrs. Haliburton*, *Robert Cannell*, *Incognito*, *Sir Stafford Carey*, *Venus*, and *White Venus* in the incurved section are often met with at shows, and judges express surprise at these older sorts remaining so long to take the place of more worthy additions to the various sections.

Perhaps cultivators will think over the matter a little, and see if they are not wasting valuable time in cultivating what I consider little better than worthless now the opportunity for revising the lists is so easily available.—SADOC.

#### CLAREMONT, TAUNTON.

CLAREMONT, the residence of W. H. Fowler, Esq., J.P., Mayor of Taunton, and the recently elected Chairman of the Floral Committee of the National *Chrysanthemum* Society, is situated a little more than a mile from Taunton to the south-west thereof, on high ground and in one of the pleasantest of the beautiful suburbs of the town. Five years since, as I was told by its owner, the place was wild and bare, a fact scarcely realisable until one thinks of the possibilities implied in a liberal outlay, combined with energy, taste, and a splendid climate. Gardeners who have lived only in the north could scarcely imagine it possible for *Conifers* and shrubs to grow as rapidly and freely as they do here.

But it is not the ornamental trees and shrubs, however fine, that Mr. Fowler is so proud to show his visitors. No! turning abruptly to me as we enter the garden, he remarks, "We have some *Chrysanthemums* to show you," and such I soon found to be the case. Calling his gardener, he led us to a range of span-roof frames, and lifting up the first light of these, disclosed to view the finest plants I have seen this season. All were in 6-inch pots and possessed remarkably large thick foliage and stout stems, but very dwarf and short-jointed. *Mrs. Alpheus Hardy* is represented by some half dozen plants, as strong and robust as the others. Mr. Fowler says he finds no difficulty in flowering it freely and well; his plants have just been topped or pinched, and he will take the first flowers produced from the resultant breaks, two to each plant. In the compost for this variety he uses peat and sand, potting less firmly than for other varieties, and finds that so treated it makes roots freely and grows with vigour.

The summer quarters of his plants are novel and instructive. A level plateau, on the highest part of the garden, is laid down with grass, and at intervals of about 6 feet apart are the lines for his plants; along these lines, fitting closely end to end, are trays each about 6 feet long, 1 foot broad, and 3 inches deep, formed of zinc or

sheet iron, and well painted. These are kept constantly filled with water, and in them are placed what look like short stout drain pipes about 6 inches deep and the same in diameter; upon these stand the pots containing the *Chrysanthemums* surrounded entirely by water. Thus neither worms, slugs, nor earwigs can ever reach the plants; and in addition Mr. Fowler believes the plants derive much benefit from the vapourised moisture constantly rising amongst their foliage. Stout stakes and wires strained between them in the usual form are adopted for supporting the plants, and earwigs are prevented climbing these stakes by bands of cotton wool put tightly around them, at about one foot from the ground, and these kept saturated with petroleum.

*Chrysanthemums* are not, however, the only flowers the culture of which is here made a speciality. Tea Roses, Gladioli, double Tuberous Begonias, and Freesias all have a like distinction accorded them. The *Chrysanthemum* house is now devoted to Tea Roses in pots; fine healthy plants free from mildew and insect pests and carrying many splendid blooms, amongst which we specially noticed Sappho (Paul) a recently introduced variety resembling as here seen a good Catherine Mermet. Outdoors an immense number of Tea Roses are grown in beds, as standards upon Briar stocks, and are looking wonderfully well. I asked Mr. Fowler if his losses amongst these, grown in this manner, were not often severe in winter, but he assured me such was not the case. Unfortunately the climate of Taunton is not to be found generally throughout England.

More than 1000 corms of Gladioli, all the best varieties, are grown in beds of four rows each, with about fifty in each row, and many are the prizes Mr. Fowler has secured for these and his Roses. Double Begonias have a house specially devoted to them, and very vigorous and strong they are looking. They are now in 9-inch pots and look as though they will make specimens 2 to 3 feet through. A large number of single varieties are bedded out in summer, and these are now making sturdy vigorous growths planted out in cold frames, so that being freely ventilated and well hardened, they may be lifted and transplanted when required without check or injury.

Freesias are extensively and well grown, these also being Mr. Fowler's favourite flowers. They are all grown in large square seed pans occupying shelves near the glass in a cool house, and the number of long spikes now furnished with plump seed pods testifies to the freedom with which they have flowered. Mr. Fowler thinks his practice of leaving them upon these shelves exposed to the fullest sun well into the summer, so that the young bulbs become thoroughly ripened, contributes much to his success with them. When taken down therefrom each season the pans are emptied and refilled, using fresh compost and assorting the bulbs into their respective sizes. They increase very rapidly, and he has many to give away to friends each season.

Another feature of Claremont is the immense numbers of Narcissi, all the best varieties intermixed and planted in grassy banks adjoining to the lawn. These have a most charmingly natural and free appearance growing amongst the uncut grass, which forms a splendid setting for them, and constitutes a scene at once novel and pleasing to every beholder. On a farm near, during the past autumn, five thousand bulbs were planted amongst the meadow grass for naturalisation. Mr. Fowler is a most enthusiastic floriculturist, and his ideas and wishes are most loyally supported and ably carried out by his gardener, between himself and whom a perfect accord and sympathy appear to exist, as it should always be between employer and employé.—W. K. WOODCOCK.

### HAZEL-BUD GALL MITE.

THIS insect threatens to prove as destructive to Cob nut and Filbert trees as the Black Currant-bud gall mite (*Phytoptus ribis*, Westw.) has to Black Currant bushes in many parts of England, especially in the North, also in Scotland, for some years past.

The Hazel-bud gall mite (*Phytoptus coryli*, Frauenf.; *Calycophthora avellanæ*, Amerl.) was first observed by Dujardin (Ann. des Soc. Nat., 1851). It was also noticed by Dr. Amerling of Prague and Dr. Kirchner of Taplitz, two Hungarian naturalists, about that time; and Kaltenbach states, in 1863: "This mite, according to the observations of Dr. Amerling, M. Kirchner, and ourselves, deforms the leaf buds into cone-shaped, scaly galls, which fade early, and never unfold or produce fruit." The term "cone-shaped, scaly galls" only applies to the configuration of the infested buds in the axils of the leaves in late summer, they being in August considerably enlarged, and by September present the corticated, scaly, corrugated appearance of catkins just emerging from the buds at the bases of the leaves. In that month, and sometimes in August, the affected buds are round and flattened at the apex, considerably swollen—quite as large as a full-grown Marrow Pea, and of similar shape, with a brown, scaly exterior. The mite-infested buds differ from normal wood or fruit buds in this essential particular—namely, they are not only then (September) four times the size of a fruit bud, but the scales of the buds are open and hypertrophied, with a ball-like swelling in the centre, while, in the case of a wood bud being infested, there is no catkins being pushed from its side. The fruit buds of Hazel, Cob nut, and Filbert trees are rounded and never push catkins from their sides, for, if cut open and examined in September with a good lens, the growth of the following season will be clearly seen—the embryonic shoot and leaves terminated by its cluster of nuts. Such a bud is always solitary in the axil of its respective leaf; a wood bud may also be without a catkin-producing bud by its side, but it is from the side of a wood bud that catkins appear in due course. The catkins, therefore, owe their presence

to the preservation of the wood bud, for if anything happens to the wood bud or it does not receive sufficient support, catkins are not formed and pushed from that joint. A fruit bud infested with mites cannot produce fruit, nor a wood bud similarly attacked bear catkins by its side, for the simple reason that the forces of the wood bud are expended in the production of the gall, their presence or otherwise depending on the preservation of the wood bud and the amount of support it receives. It is essential, therefore, that the buds first formed in the axils of the leaves remain normal for the ultimate formation of male or female blossoms in embryo, those depending on the trees receiving the needful support and its due assimilation, for if either of these are defective wood buds only will be formed, plethora on the one hand, and poverty on the other hand, being alike fatal to fruit production. Why one bud should have formed within it the male and another the female structures is not known, but it is well to understand that gall mites attacking either form of bud will prevent their unfolding and producing either growth or fruit.

If the buds of Hazel, Cob nut, or Filbert trees infested with mites are examined in spring they will be found of the appearance shown in the illustration, fig. 61, A, a spray of Hazel, natural size. Three buds, *a*, are infested, swollen, distorted and destroyed so far as growth of value to the tree is concerned by the Hazel-bud gall mite. They, as will be seen, are rounded and hypertrophied, without any outgrowths, and are crimson coloured, indicated by the "black" in the engraving. In the centre, this part now (April 7th) becoming fissured, and by degrees the galls crack, open, turn black and wither. Let us look inside one of these swollen buds—gall formations. If torn open there is nothing visible to the naked eye beyond a distorted swollen mass. A pocket lens discovers nothing, only shows more of the devastatory work with, perhaps, a dirty white grub. But these supposed devourers of mites are very seldom found in bud galls, and the parasitic entedon is certainly not found in the galls until they have been deserted of the mites. Phytophagous chalcidæ, also, may be dismissed as non-parasitic on mites.

The way to examine a bud-gall with a microscope, and see the hundreds of minute, semi-transparent, ashy-grey coloured mites is to cut the thinnest possible sectional slice of the interior of the gall and place it on a glass slide, with a reflector throwing light upon it from beneath. Such section is shown in B. Several active creatures, less than 200th of a line in breadth, promenade the excrescences and stump-like hairs, and eggs, affixed by their small ends mainly, interest the beholder. Some of the insects appear browsing on the tips of the stumps (*b*), others pass from one stump to another (*c*); not a few steady themselves by their caudal appendages, and clasp the stump ends with their maxillæ (*d*), while others "sun" themselves on the eminences (*e*). The galleries are very irregular and partitioned, sometimes, but not always, protected by hairs resembling the outgrowth of fungi, and called erineum. The eggs (*f*) vary as much in size as those of fowls, and they are, as seen and sketched on April 7th, equal in diameter to the average transverse one of the mites.

The specimen, C, greatly magnified, was specially selected for illustration; also the egg, D, the nucleus or head being clearly visible at *g*. As this part of the egg gains in weight it leans to one side, and the sac becomes drawn out, as shown in E. The mite ultimately emerges with four feet and the bristle-like attachments at the sides and caudal part of the body, leaving the empty sac still attached to the wall of the excrescence, as in F. When the newly hatched mites get well on their legs, and appear as C, they desert the galls, not a single one nor any trace of its former occupants being found in the discoloured, shrivelled gall but the empty sacs, with perhaps the larvæ or maggots of some fly.

What happens to cause the exodus of the mites is clearly due to their being no longer able to produce further swellings of the gall, because the sap which flowed into it in spring or from their entrance into the bud has been transferred into other channels, the tree not centring its forces on abortions, but on the growths essential to its enlargement and the reproduction of its kind—that is, the wood and buds of the current year. It should be distinctly understood that the mites must have live parts to act upon, otherwise they cannot produce galls, which are due to drops of poison deposited by the mites on the host, producing chemical changes, and hypertrophies yielding their essential food. This cannot go on the same part indefinitely, for what tends to produce a swelling does so at the expense of another part of the host, so that there is no hypertrophy without its corresponding atrophy, and culminating in the parasites exhausting the supplies of food, therefore, perforce of necessity, they seek fresh pastures.

What becomes of the mites from their departure out of the old galls to their presence in the new buds of the Hazel, Cob nut, or Filbert trees in autumn? Dujardin states that he found the same species of *Phytoptus* he detected in the Lime leaf nail galls in the malformed and distorted buds of the Hazel. M. Dujardin's figure of the Lime-leaf nail-gall mite (*Phytoptus tillæ*, or *Ceratocnema extensum*, Bremi), in the Bethnal Green branch of the South Kensington Museum, Aptera, case x., No. 16, is a very different one to that in the engraving C; in fact, they are different species. M. Dujardin's mistake is easily accounted for by his being an early worker, though preceded by M. Duger (1832-1834) and M. Turpin, who observed, in the nail-galls of the Lime leaf, a number of very minute semi-transparent fleshy mites of a new and hitherto unknown form—"a narrow creature with two pairs of small legs at its head, and some kind of sucker apparatus at its tail, on which it rests and raises itself, swaying about its body." This accurate description of a gall mite cannot be improved upon; but M. Turpin regarded "the creature" as a species of *Sarcoptes*, yet his figure accords with Dujardin's of

*Phytoptus tillæ*, and Reaumur is believed to have seen the makers of the galls a hundred years before anybody else.

Now there are only five species of bud gall mites. *Phytoptus betuli*, living in Birch buds; *P. coryli*, infesting Hazel buds; *P. persicæ*, attacking Peach buds; *P. ribis*, living in Black Currant buds; and *P. taxi*, infesting Yew buds. None of these has been proved to live in leaf galls, or in erineum hairs on the leaves. There certainly is a resemblance to each other in all mites, otherwise they could not be formed into one genus, but there is also a difference, hence their division into species, and the view of mites transferring their attacks—living in summer in leaf galls or erineum and in winter in bud galls—is mere conjecture.

The Hazel bud gall mite would be most likely, assuming the mites to have different hosts at different seasons, to exist on the Thorn or Maple in summer; but the Thorn *Phytopti* is a transparent whitish creature, and appears in May, forms erineum rust on the turned-up edges of the

Apple tree, *Phytoptus pyri* and *P. mali*. These are transparent white, accord well with Scheuten's sketch (copy) at the Bethnal Green branch of the South Kensington Museum, Aptera, case xvii., No. 4, and they never attack the buds of the Pear or Apple, and only leave the trees when forced to emigrate through scarcity of food. They, however, do something quite as bad, or worse—produce a knotted, warted, cankerous condition of the twigs, which becomes sealy in the limbs, weakens, and sometimes kills the trees, as I observed in three orchards lately. Mr. Harrison Weir and Mr. J. Hiam are in this respect quite right as regards this form of canker, and once a tree, Apple or Pear, is attacked by these mites it continues so year after year, adjoining but detached trees remaining free for some time, or until the infested trees become impoverished or dies, then emigration sets in in earnest, and the disease-resisting trees, so called, become a prey to the mites. The leaf gall mites, however, are in some cases great rovers, *P. oxyacantha*, Am, being, perhaps, the most remarkable; but the bud gall mites carry

FIG. 61.—HAZEL-BUD GALL MITE; INFESTED AND CLEAN GROWTHS.

SUMMARY OF REFERENCES TO THE ILLUSTRATION:—A, Hazel twig, natural size; a, buds infested with Hazel-bud gall mite, *Phytoptus coryli*; j, unattacked terminal bud; k, basal bud; m, catkin-bud destroyed; n, wood bud by the side of catkin-bud; o, point of cutting off infested growth for burning. B, very small sectional part of bud gall, greatly magnified; b, mite browsing on stumpy hair; c, mite passing from one stump to another; d, mites holding by their caudal appendages and clasping the stump ends with the maxillæ (lips); e, mite at rest; f, eggs of mite. C, specimen mite, greatly magnified. D, egg of mite, highly magnified; g, nucleus or head. E, sac drawn out by mite before emerging, highly magnified. F, empty sac, greatly magnified. G, twig of Hazel infested with gall mites; k, terminal bud attacked, also the next below; l, unattacked wood bud; i, basal buds. H, clean growth of Hazel twig, natural size; p, terminal growth, with nut cluster in centre. All the figures are from life (April 7th, 1893) except E and F, which are from 1892 drawings, to the same enlargements as B, C, and D.

leaves of a greenish yellow colour; they also form light brown egg-shaped bells and club-like galls. When autumn arrives these *Phytopti* have blackened and destroyed the points of the young shoots. They are not bud gall makers. *Phytopti* produce beautiful galls on Maple leaves. They do not enter the buds in autumn and make galls of them for their winter sustenance.

On the other hand, there is not any erineum on Hazel leaves in summer, and the nearest resembling mites are those of the Pear and

off the palm for emigration and devastation, the Hazel bud mite being widely distributed.

This mite does not leave the attacked buds before the Hazel is well in leaf, and the young buds forming in the axils of the leaves. The young growths, shoots, and leaves are hairy; the mites, as shown by the late Professor Claparède, possess hair-elaspers, which he, as well as the late Mr. C. Darwin argued, "must have been independently developed, as they could not have been inherited from a

common progenitor, and in the several groups [of the parasitic mites] they are formed by the modification of the fore legs, of the hind legs, of the maxillæ or lips, and of the appendages on the under side of the hind part of the body."—"Origin of Species," page 143). Now, without these hair-claspers the mites would make little progress over a hairy surface, as that of a shoot, intervening between its old domicile and a newly formed bud, which it has to form into a new habitation for itself. When this migration from an old withered gall takes place varies, sometimes in May, often much later, always by the time the buds are formed, for it must take advantage of their swelling or formation, otherwise it cannot produce a gall, and the hair-claspers facilitate its progress from one part of the tree to another, or from one bush to its neighbour. Whether the mite can and does derive nourishment from the tree hairs is not known, but it cannot live long outside the gall, and it is pitiful to see the frantic endeavours of the mite to find something to clasp by rearing itself erect and moving its legs and maxillæ, and it soon dies. It may be different on a young growth—I have not found one—and it is questionable if the mites do more than pass from an old gall to a new bud. That certainly occurs by midsummer, and the growth of the bud attacked is then abnormal, by August as large as a field Pea, and a gall as large as a Marrow Pea is formed by September.

The mite always attacks the wood and catkin, or fruit buds, passing over the small wood buds at the base of the shoots, A *h*, and G *i*. Sometimes the extremity bud, A *j*, is not attacked; in other shoots the terminal bud, G *k*, is infested, whilst a wood bud, G *l*, has been passed. Mites evidently can make a mistake by destroying the bud, A *m*, a catkin bud, of no value for making a gall, while the wood bud, A *n*, remains intact. This is no doubt a consequence of the mite or mites having dropped a drop or drops of poison into the centre of the wrong bud and killed it, for, as before stated, no catkin bud ever is made to produce a gall, but the wood bud may before that and the catkin bud become distinct parts, and this is determined by midsummer, if not sooner, and it goes to prove that the mites pass direct from their old habitations and commence at once to form new out of the young buds then receiving the assimilated matter abundantly by the leaves. The galls are considered to be due to irritation—a mere guess—for no irritation will produce a chemical change in the juices of the plant, and that certainly takes place, the green colouring matter (chlorophyll) being abstracted, and red first, then brown, and lastly black is the colour of the excrescences or galls. Poison, a minute drop or drops, is unquestionably the exciting cause of the galls, and the progressive growth of the excrescences may be due to the same cause, for until the growth ceases there is no exuvie in the gall, afterwards abundance, and the mites soon clear out of such a fouled nest—old and young emigrating together.

A clean growth, H, is easily detected in spring from infested A and G. The remedy is to cut off and burn the affected growths, say at the bars, O, not later than the vernal equinox or the decay of the catkins, by which time the flowers will have been fertilised, not deferring it later than the time the healthy shoots are pushing growth with the clusters of nuts, H *p*. The mites and eggs are then in the galled buds, and the remedy is sure.—G. ABBEY.

#### SOUVENIR DE LA MALMAISON CARNATIONS.

IN the course of remarks on these Carnations a writer on page 284 makes statements to which I would like to refer. First, as regards Madame Arthur Warocqué, which I recommended shortly after the introduction of this variety from Brussels. It is a good Carnation, but it has no right to be classed as a Malmaison, and it is time that it should cease to be termed one. If I recollect rightly, plants in flower were presented to the Floral Committee of the Royal Horticultural Society, but were passed, while some time after the thirty-year-old pink Malmaison was honoured with a certificate.

The second point I wish to refer to is that cool treatment suits the Malmaisons best. Cool treatment has one serious drawback, inasmuch as the period of flowering has to be left to the time natural to the plant. In these days this is a matter to which most gardeners cannot confine themselves. The present year all my plants are autumn layered, yet I am now able to cut flowers from the central spike. Under cool treatment I should have been obliged to wait for another year until I could obtain flowers from the side growths; but the latter in my case will follow close on the central growth, and yield flowers throughout summer and autumn. Under such circumstances, I should be unwise not to keep the plants in a growing temperature, which I am inclined to believe is not inimical to the health of the plants, and which gives conditions by which the best blooms are produced.

With regard to which variety is the best, my opinion is that the old blush Malmaison, when produced in good form, is superior to the others. Then the deep pink, or Rothschild variety, as so many now term it; next Lady Middleton; and then one which I saw exhibited in London as a pink form, but which I consider unworthy of cultivation.—B.

#### A TRIP TO RENFREWSHIRE.

ON the 25th ult. I paid a visit to the residence of the late "Renfrewshire Bee-keeper" for the first time since his death. The thermometer stood as high as 68°, and a short distance from the mansion lay a large wreath of snow. I scanned many old favourites, amongst which were Plum trees sadly scourged by the blue tits. Although everything was there as usual that pleased the eye, the absence of our true friend made

sadness that not even the lovely flowers could dispel. Hepaticas in various shades were charming, Croci in millions made a feast indeed to the eyes of those who can appreciate, while the Scillas in variety, from the pure white to the pink and blues of different shades, added richness to the scene. The huge clumps of Leucojums, large in flower and foliage, with their sweet fragrance, showed well amongst the shrubbery, and how well adapted they along with the Scillas are for woodland decoration. Daffodils and Snowdrops were very attractive, and are in this quarter widely distributed, the latter being mostly of the double varieties.

I observed one single Snowdrop, having flowers not unlike Elwesi, but the foliage was from 1 foot to 15 inches long, by 1 inch broad. Can Mr. Arnott name it? Those that interested me most were some of the Crimcan form I sent him some fifteen years ago. Each flower, including the seed pod, measured 1½ inch long, being three-eighths of an inch larger than they grow with me. When I saw them it recalled to my mind the large one mentioned by Mr. Arnott as being found at Galston, and suggested that soil and situation may account for all the extra size.

The great contrast in size of these flowers when compared with my own gave me hopes of some of my own hybrid seedlings. They are larger than the Crimean, or any other variety I have, with the additional property they do not reflex their petals to the same extent as most other varieties, remaining intact, more bell-shaped, while the inner tubes remain impact, the petals never separating while the flower lasts.—W. T., Blantyre.

#### SHOW OF CAMELLIAS AT WALTON LEA, WARRINGTON.

ON Sunday and Monday, April 9th and 10th, the grounds surrounding this beautiful residence were, through the kindness of John Crosfield, Esq., thrown open to the public that they might spend a pleasant afternoon and view the Camellias which are now in full bloom. Brilliant sunshine prevailed on both days, and thousands of persons, young and old, made their way to Walton, either on foot or by means of conveyances, which ran to the entrance of the gardens. The number of visitors on Sunday was estimated to be about seven or eight thousand, and on Monday over two thousand, and not the slightest damage was done. What a treat to those hard toilers must this feast of Camellias have been! And if to them it is equally so to the practical gardener, who hears in these days the cry that Camellias are out of date.

I will in as few words as possible try and describe the house in which Mr. Kipps, the gardener, grows the plants so well. Originally it was a three-quarter span 50 feet in length, but this becoming so crowded the house was enlarged to 100 feet in length, 15 feet 6 inches in width, and about the same in height, the back wall being about 10 feet, and facing east. A path runs down the centre of the house with a border along each side. Here are planted the Camellias, and I would like your readers to picture in the border next the back wall a row of perfect pyramids some 14 or 15 feet high, clothed from bottom to top with the most luxuriant foliage, every shoot carrying perfect flowers, and the row next the front of the house about 10 feet high, all superbly flowered, and then they have only a faint idea of the gorgeous display they make. Viewed from either end the sight is grand.

In the back border the following varieties are grown:—Lavinia Maggi, Elegans, De la Reine, Hendersoni, Ochroleuca, Imbricata, two or three specimens of the old Double White, Commandatore Batti, and Jeffersoni. The front bed contains the following:—Jenny Lind, Candidissima, two Lady Hume's Blush, Jubilee, Duc de Bretagne, Fimbriata, Tricolor, Auguste Delfosse, the gorgeous Carolina, with its deep crimson flowers 6 inches in diameter, and the red and white varieties of Mathotiana, the former having many flowers over 8 inches in diameter, and an unnamed pink variety. On the back wall are Reticulata (so very seldom met with, but how beautiful with its large rose-coloured flowers!), Alba plena, Pelaskea, Madonna, Sacchi Nova, and a fine white variety with rose marbling. No insects are to be seen, the garden engine playing an important part in their extermination. The borders are well drained, and good sound loam forms the compost.

Credit is due to Mr. Kipps for the excellent condition of the plants; but throughout the grounds the same conditions are observable. A large number of ripe Strawberries were to be seen in various houses, plenty of flowers alike in conservatory and plant houses, and vegetable ground and pleasure grounds neat and trim.—R. P. R.

#### THE GHENT SHOW.

WE did not send a reporter to Ghent this year for two reasons:—1, Because the usual Press ticket did not come to hand; 2, because much smaller interest appears to have been manifested in the event than has been evident on former occasions in this country. We could only ascertain that two or three of our home firms would enrich the Show by their produce, the majority not contributing, though several would attend to see the general exhibits.

We have often described the quinquennial shows. They are always great, as they should be after five years of preparation, always picturesquely arranged, always very much like each other in general character, and visitors always receive a pleasant reception. There is always an imposing display of lofty Palms and Cycads, with luxuriant foliage plants, floriferous masses of Indian Azaleas, such as cannot be seen elsewhere, glowing banks of hardy Azaleas, with an extensive

display of Orchids. In these plants, however, England excels, also in practically all other flowers with the exceptions above named.

English groups have often brightened the great floral halls of the old Flemish city, and this year they were not wholly absent. A hundred *Hippeastrums* ("Amaryllis") were sent from the renowned collection of Messrs. Veitch & Sons, Chelsea, and these could not be staged anywhere, no matter how rich the surroundings, without commanding attention and admiration. Then the consignment of *Ericas*, *Epacris*, *Pimeleas*, *Aphelexes*, *Boronias*, and plants of that nature such as Messrs. Cutbush & Sons sent over would constitute a feature, and their chaste beauty could not fail to be appreciated. With the exception of the above firms, and of Messrs. F. Sander & Co., we have not heard of other of our home friends sending plants or flowers. The St. Albans firm we are informed had the honour of winning the first prize for the following six new plants:—*Strobilanthes Dyerianus*, *Alsophila atrovirens*, *Alocasia Watsoniana*, *Ludovia crenifolia*, *Dracæna Godseffiana*, and *Dracæna Sanderiana*. Messrs. Sander & Co. also exhibited, not for competition, *Carludovica Laucheana*, *Maranta Sanderiana*, *Oreopanax Sanderianum*, *Pandanus Baptisti*, *Vriesia tessellata variegata* var. *Sanderæ*, and *V. fenestralis Germinyana*.

The grounds surrounding the casino always present a different appearance from the "outside" shows at home, inasmuch as we possess none of the stately globular and pyramidal Bay trees in tubs, grown and trimmed by years of patient labour and skilled attention. They produce an effect all their own, but are too formal to meet with popular favour in this country, though they afford appropriate ornaments to terraces. There is always a great show of glass structures, but it may be added when Messrs. Foster & Pearson exhibit, as on the present occasion, the substantial character and finish of their work stand out bold and clear amongst whatever may be seen around them, though it is becoming evident that the Notts exhibits have not been without educational effect on observant natives of the busy, and we are sorry to say now troubled, little kingdom.

Besides the showing of plants, flowers, and gardening appliances, there is the banqueting of the jurors and others—always done well, not to say lavishly—with attendant glass chinkings, effusive handshakings, oratorical displays, and operatic wind-ups; then comes the visiting to nurseries and elsewhere in search of novelties; and after this the floral pilgrims wend their way to their respective homes in different lands, leaving a little money and sundry orders behind them, also work for the busy Belgians in clearing out their stocks. The quinquennial is well known as a gigantic trade organisation, splendidly managed, and the efforts of the shrewd and enterprising conductors to make it a success and the talk of the world is beyond all praise. That is what they do, and no other body in Europe, if in America, could do it so well. All the nurserymen appear to the unsophisticated visitor as if they were members of one great firm till the event is over, then the usual trade rivalry is resumed and continued till the next Quinquennial.

This general sketch of the Ghent gatherings will do as well as going to the Show, to repeat practically what has been said before, and it has this advantage for the sketcher—namely, he escapes the *mal de mer*.

#### HARDY FRUIT GARDEN.

**Disbudding Fruit Trees.**—The commencement of this important operation has been rendered necessary somewhat earlier than usual, owing to the advanced state of many trees which the early spring has pushed forward into growth. Though, however, a beginning has been made in many districts, it is not desirable to complete disbudding all at once, but to extend it over a period of some weeks.

**Apricots on Walls.**—These being the earliest in growth need attention first. Carefully note every portion of the trees, and rub off or remove cleanly with a sharp knife all the misplaced shoots. Such growths on wall trees are usually situated behind the branches and facing the wall, where they practically are of no use. In all cases commence disbudding in the upper parts of the trees, where activity and vigour is first apparent. Well thin-out shoots which proceed from the front of the branches. These, if left, form the foreright shoots or breastwood, and only a fair number should be retained. Their position in front of branches does not enable them to be laid in as succession shoots, so they may be pinched at the second pair of leaves, resulting growths afterwards at one leaf. Shoots of this description will form artificial spurs, upon which fruit will eventually be produced. Well-managed Apricots also form natural spurs freely, which must always be preferred if situated in suitable positions. A fair number of young shoots all over the trees must be selected from the growths at the base of the fruiting shoots or originated in other positions to take the place of the latter when they are cut out in the autumn. The shoots on the fruit-bearing wood gradually reduce, leaving a few here and there below the young fruit if necessary; but in all cases level with or above the fruit, one vigorous extending growth ought to be left to aid the circula-

tion of sap to the swelling fruit. Such shoots are pinched when three or four good leaves have been formed.

**Peaches and Nectarines.**—These require similar treatment, but differ from the Apricot in usually being confined to young wood only for bearing fruit. Peaches and Nectarines do not furnish natural spurs so readily as the Apricot, but artificial spurs may be produced by following the same method of pinching as recommended for the latter. Spurs, however, are not essential, as enough well-placed young wood can be secured annually. Commence the removal of superfluous wood growth by rubbing or cutting off all the ill-placed growths, those at the back being first attended to, afterwards those which point outwards, forming the breastwood eventually, if not removed. If retained they could not be utilised for training in, being so awkwardly placed. At the same time proceed to thin out gradually the growths situated in the more favourable positions, selecting one of medium vigour at the base of each fruiting shoot for training in. Select one at the top also, and reserve this for attracting sufficient sap to the fruit to aid its development. Most of the growths which lay between may be removed before disbudding is finished. One-third of the tree or a little less can be operated on at a time, in all cases commencing at the top, working downwards, and proceeding gradually.

**Plums and Cherries.**—The removal of useless shoots is likewise beneficial to these as to other trees. Disbudding is chiefly practised to remove gross shoots which are easily detected, as they commence to grow with exceptional vigour. Of the other growths on wall trees some may be thinned out, the best placed reserved for training in as extensions, or to fill vacancies between the principal and subsidiary branches, the rest pinched back when two pairs of leaves have been formed. Restricted trees in the open ground, such as espaliers, pyramids, and small bushes, will also be benefited by removing many of the inward growing shoots, which would be liable to choke the trees with growth that cannot possibly be perfected from their inability to obtain light and air. Suppress all gross shoots which start away from old wood, and for which no place can be found.

**Apples and Pears.**—Look over the trees on walls, so that any useless shoots and those pointing in wrong directions may be removed entirely. Judicious thinning, if necessary, will improve the shoots left, giving more abundant light and air to the short promising buds close to the wall, and which it is desirable should soon develop into fruitful conditions. Besides the wall trees, espaliers, bushes, and pyramids those in the open will be much benefited by close scrutiny. The weakest buds that bear no promise of future usefulness closely remove, shoots of gross or undue strength rub off, and those retained leave sufficiently wide apart, so that a fair share of sunlight and air can penetrate to the interior of each tree whatsoever its form.

**When to Disbud.**—The weather regulates the operation of disbudding considerably. When moist and warm growth is more active, consequently less time can elapse between the removals. During the prevalence of cold drying winds the sap does not flow freely, therefore it would be unwise to disbud except very sparingly. The first disbudding should take place as the flower petals are falling, the second a few days afterwards, or longer, according as the trees require greater or less attention. Follow on at intervals until all the superfluous shoots have been discarded.

**How to Disbud.**—The removal of soft young growths can mostly and easily be effected with the finger and thumb, but sometimes difficulty is experienced in accomplishing this without injuring the surrounding bark owing to the base of the shoots having attained a woody character. They should, therefore, in such cases be detached with a sharp knife, as to tear and injure the bark is decidedly wrong, frequently leading to canker in some trees and gum in others.

#### FRUIT FORCING.

**Peaches and Nectarines.**—*Earliest House.*—The early varieties started in December are now taking their last swelling, Alexander being first, closely followed by Early Louise. The fruits must be kept dry after they approach ripening, and the leaves having been drawn aside and the fruits raised by means of thin laths placed across and secured to the trellis so that the apex will be exposed directly to the light, they will be thus coloured well, and possess the highest quality. Syringing must be continued in the case of such varieties as Early Alfred, Hale's Early, and Royal George or Stirling Castle until the fruit commences to ripen. Supply water to inside borders liberally, and give liquid manure to weakly trees carrying a heavy crop. Keep the shoots well tied down, thinning them where required, so as to give the sun and air access to the fruit for the ripening process.

*Trees Started Early in January.*—The fruit being now stoning must not receive a sudden check, as that occasioned by cold air in the day and too close and high a temperature at night and on dull days. A temperature of 60° to 65° at night in mild and 5° less on cold nights is sufficient, 65° not being exceeded on cold dull days, but allow 70° to 75° with gleams of sun, and 5° to 10° advance on bright days, with free ventilation. Expose the fruits to the light, for the darker they are before ripening commences the higher coloured and better flavoured they will be when ripe.

*Succession Houses.*—Trees started in February are swelling the fruit freely. Assist weakly trees with liquid manure or surface dressings washed in, but avoid stimulating them too much, as that is prejudicial to stoning, and avoid sudden depressions of temperature or the admission of cold air. A night temperature of 55° to 60° is sufficient for the present, allowing an advance to 65° by day with air, and 70° to 75° with

full ventilation. Attention must be given to the following operations according to the respective condition of the trees.

**Disbudding.**—Too early disbudding has a tendency to hinder the first swelling of the fruits, and there is danger of rendering the shoots too gross, which is inimical to the fruit stoning satisfactorily and the future crop. It should not be begun until the fruit is well set and swelling, yet there must not be any delay in commencing this operation as soon as the shoots can be displaced with the finger, continuing it from day to day, or at short intervals, until all the superfluous growths are removed, leaving only those required for the perfection of the current crop for producing next year's and the extension of the trees. One shoot must be trained in from the base of that now bearing, another on a level with or above the fruit, pinching it at the second or third good leaf, and a growth encouraged from the extremity of extensions, training those in their full length, having the main branches about 12 inches apart and the bearing shoots 15 inches asunder, calculating from the base on last year's wood. Close training results in weak overcrowded growths; all should be well exposed to light and air to secure sturdy shoots with well developed buds and thoroughly ripened wood.

**Thinning the Fruits.**—When the fruit is the size of horse beans the smallest, ill-shapen, and worst placed, as those on the under side of the trellis, should be removed first, commencing with the weakest parts of the trees, thinning proportionately more there than on stronger wood, which from carrying more fruits will tend to the equalisation of the sap, consequently vigour of the trees. The fruits should be thinned again when the size of small marbles, doing it in all cases gradually, and after the fruits attain the size of a Walnut only a few more than those required for the crop need be left to meet casualties in stoning. One fruit of the large-fruited varieties to every square foot of trellis covered by the trees is a fair crop. Those that produce medium sized fruits may be left at every 9 inches square, which is a suitable distance for Nectarines.

**Tying-in the Young Shoots.**—To heel-in the young shoots early is essential to symmetrical training, and it must be done so as to give the proper direction to the growth without breaking it, leaving sufficient space in the ligature for the swelling of the shoot. This is of the utmost importance as a safeguard against gumming. After the right inclination is imparted to the shoots very close tying-in is undesirable until the final one before the fruit commences ripening.

**Syringing the Trees.**—This must be practised twice daily on all fine days and on all trees not in flower or with the fruit ripening, for they must be kept free from red spider, as when it gets a hold it is difficult to dislodge, and allowed to have its own way it materially affects the present and succeeding crop, often ruining both. In dull and wet weather syringing should not be practised in the afternoon, and in the case of vigorous trees less syringing is necessary than for those with stouter foliage. The afternoon syringing should be done at closing time, so as to have the foliage nearly dry before night.

**Feeding and Watering.**—Whenever inside borders become moderately dry a thorough supply of water should be given to render it regularly moist to the drainage. Watering borders needlessly only tends to sappy growths, and its opposite extreme of dryness induces stunted wood, with a preponderance of blossom buds, and aids red spider. Weakly trees may be assisted with nitrogenous manures, as liquid manure from stables or cow houses properly diluted with water, mulching the border with short partially decayed manure, which will keep the roots at the surface, but it is little use unless kept moist, yet not constantly soddened. Free growing trees, on the other hand, should have due supplies of superphosphate, say 4 ozs. per square yard, but no mulching, or only slight to prevent the soil cracking and keep it evenly moist. Thomas' phosphate powder may be used where the soil has become close and full of humus at a similar rate to the superphosphate, both being employed at intervals of about six weeks as the cases require.

**Late Houses.**—Still continue to fertilise the blossom, selecting the early part of fine days for the operation. Where there are means of affording heat the temperature should be maintained at 50° by day, and 40° to 45° at night, in all instances accompanied by a little ventilation at the top of the house, increasing it when the temperature reaches 50°, and having it full at 65°. In unheated houses commence ventilating at the same temperature, and close at 65° when there is a prospect of frost at night. A light syringing after the fruit is set will aid it in casting off the remains of the flowers, but it should be practised early in the day, so as to have the trees and house dry before night.

**Pines.**—Young plants in course of preparation for fruiting are rendered soft, drawn, and weakly in growth by a close atmosphere, which should be avoided by the employment of as little fire heat as practicable, husbanding the sun heat, and maintaining a moderate moisture in the house, by which means robust growth, combined with a sturdy habit, is secured. Maintain, however, a night temperature of 60° to 65°, and 70° to 75° by day. Commence ventilating at 75°, gradually increasing with the temperature to 85°, keeping it through the day at that heat from solar influences, or 90° to 95°, with abundance of air. Sprinkling will be necessary at closing time, also in the morning, but do not close the house at a high temperature, and syringe the plants about twice a week. Keep the bottom heat steady at 85°, or not less than 80°, nor exceeding 90°. Examine the plants regularly twice a week, and when water is required (only then) apply it liberally.

Weak liquid manure (guano being, perhaps, the best) may be applied to plants swelling, but not ripening their fruits, and little or no water should be given these. As the fruit ripens both plant and fruit may be removed to a cooler house, which will permit the fruit being kept sound for a lengthened period, longer, perhaps, at this time of year than any other.

When the suckers of fruiting plants become large enough screw out the centres of those not required for stock; one, or at most two, suckers should only be retained to a plant. In the case of large panes of glass, and the sun very powerful, a slight shade for an hour or two at midday will be of service; but with small panes of glass it will not be needful. If the plunging material settles down from the pots apply fresh to the surface to keep the pots from being acted on prejudicially by the atmosphere.

**Melons.**—*Earliest Crops.*—The fruits are now approaching maturity, March having been the finest month for Melons during the past eighteen years—rainless, sunny, and not particularly sharp. In damping the house avoid wetting the fruits, as that would cause those with hard rinds to crack, and, though a drier atmosphere and similar condition of the soil is desirable when the fruit is ripening, its quality or finish depends on clean healthy foliage, and if care is taken to keep the plants healthy a second crop of fruit will set without much trouble. This crop will be considerably advanced in swelling and without prejudice to the first crop by the time it is ripe, all flowers being removed after a sufficient number of fruits has been secured for the crop, attending to the usual stopping.

When the first crop is gathered supply a little fresh warmed lumpy loam and water freely, following at once with rather thick but not overstrong liquid manure, and sprinkle a little superphosphate and nitrate of potash on the bed occasionally, say a small handful of this mixture, three parts dissolved bones, one part powdered saltpetre, and one part ground gypsum mixed. Keep well syringed, well nourished, and the plants will supply not only a second crop of fine fruit, but sometimes a third or fourth, provided bad leaves are removed, new growth encouraged, and it is kept clean and healthy.

**Succession Houses.**—Plants in these require frequent attention for stopping, tying, thinning the shoots, impregnating the fully expanded blossoms in the middle of the day when the pollen is dry, acting upon a sufficient number on a plant about the same time to secure a regular set, so that the fruit may be of a simultaneous stage of swelling, which is essential to full crops and uniformity and size. Houses that have been used for winter Cucumbers may be utilised for Melons. Remove all the old soil, scrub the woodwork with soap and water, using clear only for the glass, and wash the walls with limewash with a handful of sulphur in each pailful. Good turfy loam, with an admixture of old mortar rubbish and some road scrapings, form a suitable compost. If heavy add about a fifth of burned clay to the loam, placing the compost compact in the ridges or hillocks, and when warm put out the plants and press the soil firmly around each.

**Pits and Frames.**—Excellent Melons can be grown in these after they have been cleared of forced Potatoes. The seed to furnish plants should now be sown and the plants be grown and stopped at the second rough leaf, so as to have them strong, but not stunted by keeping them root-bound, for planting in the beds, which, as a rule, will only require an addition of fresh fermenting material mixed with the old to a depth of about 18 inches, so as to generate a gentle warmth and give the plants a start, the sun heat doing the rest.

**Cucumbers.**—Plants in houses will require abundant moisture both at the roots and in the atmosphere, damping frequently and syringing the plants both ways about 3.30 P.M., closing at the same time or earlier, according to the weather. Shading will be necessary in the middle of the day for an hour or two in bright weather to prevent flagging; but with the roots healthy and abundant, and moderate ventilation, little shading will be needed. To maintain a good supply of fruit with regularity, frequent attention must be given to the stopping, thinning, and providing a succession of young growth, cutting out the bare and exhausted and avoiding overcropping. Supply an occasional top-dressing of lumpy loam to which a third of sweetened horse droppings have been added, and afford water at the roots when necessary, always before the plants are distressed, but never before the soil is becoming rather dry, as a sodden soil is very pernicious.

In watering plants in pits and frames do so sufficiently early to have the foliage dry before night. Maintain a good bottom heat by renewing the linings, being careful to avoid rank steam inside the frame by the soil being parted from its sides, or the night covering hanging over the linings. Still employ mats or other material over the lights at night, which are yet cold. Ventilate early, or at 75°, and moderately, maintaining through the day at 80° to 90° from sun heat, husbanding the latter by early closing, a temperature of 90° to 100° not doing any harm, but good, provided there is plenty of moisture. Avoid overcrowding, keeping the shoots stopped to one joint beyond the fruit, removing bad leaves as they appear. If wireworms be troublesome, as they sometimes are when turf is used, baits of Carrot inserted in holes just within the soil will attract them, the baits being examined daily, and the wireworms destroyed.

For woodlice baits of Potato, Beet, or Mangold Wurtzel, with the middle scooped out, form good traps, or a boiled Potato wrapped lightly in a little hay in flower pots, and placed where the woodlice abound, and examined daily, soon clear them. A toad placed in the frame will soon destroy the woodlice.

#### THE FLOWER GARDEN.

**Auriculas.**—Choice or named varieties are usually increased by means of slips and rooted divisions taken after the flowering period, and the more generally grown alpine section can be similarly propagated. Seedlings, however, are the more vigorous, equally floriferous, and are easily raised. If the seed was not sown last month it is not yet too late

to sow it. Fill either well drained pans or boxes with fine loamy soil to which sharp sand has been added, make this firm and level, give a gentle watering. Sow the seed thinly two hours later, and cover with fine soil. The seed will germinate more quickly in very gentle heat, but will do so rather more surely if placed in a cold frame or handlight. Cover the pan with a square of glass, shade from sunshine, and keep uniformly moist. Auricula seed is apt to germinate very irregularly, the seedlings appearing at comparatively wide intervals. The soil in the pans or boxes ought not, therefore, to be hastily broken up, the wiser plan being to carefully lift out the seedlings as fast as they are large enough to handle, placing them singly in small pots. The seedlings should be kept in a frame till the pots are becoming well filled with roots, when they may be planted out in a sheltered spot.

**Polyanthuses and Primroses.**—Seed of these may be sown either in boxes or in the open, but the seedlings will be of little service as far as flowering next spring is concerned. If the soil is at all dry moisten it prior to sowing the seed rather than afterwards, and if good room is allowed there will be no necessity to prick out the seedlings; but they will make grand plants if taken in hand early next season. If the seed was sown in gentle heat under glass early in March it will be an easy matter to grow the seedlings to a good size during the summer, or quite large enough to give a fine display of bloom next spring. If the seedlings are now in a crowded state prick them out 2 inches apart in boxes or pans of good loamy soil, and keep in a frame till well rooted, after which a sheltered or cool border and fairly good soil will suit them best. Both Polyanthuses and Primroses divide readily after flowering, and all the best forms, notably the yellow flowering varieties of the former, should be marked now, and being duly divided and taken good care of it will be possible to mass the colours next season. Seed-saving is not advisable unless the strains are extra good and no inferior forms have been allowed to flower among them.

**Violets.**—These were much injured in some instances last winter, but have grown well since, and the time has arrived for dividing and replanting. They experience the least check when lifted and divided after the first series of young leaves have matured somewhat. A strong or over-rich soil is not suitable for Violets, as it is apt to cause a rank growth, and which is the first to succumb to frosts. A free admixture of leaf soil, fresh loam, and sand to the ordinary garden soil is what Violets like, or leaf soil alone can be used. If there is any choice let the Violets have a border sloping westwards, and they are most reliable when grown among thinly disposed fruit trees. Lift the old plants with a fork, pull to pieces, and select the younger divisions or runners having a few roots attached to them. Plant them 9 inches apart in rows 12 inches or rather more apart, taking care to bury and firmly fix the whole of the hard stems. Give a watering, and roughly shade from bright sunshine for a time. The Russian section, notably The Czar, are the hardiest and most serviceable; but the doubles, including Neapolitan and Marie Louise, frequently pass safely through the winter, and are very gay in the spring.

**Violas.**—Old plants left in the open borders are fast coming into flower, but if they are required for affording a summer display, this tendency to early flowering must be checked. Dividing and replanting should take place soon or before hot weather sets in, or they will fail to become well established, and mildew complete their ruin. Give them the benefit of a liberal dressing of either good leaf soil or decayed manure about the roots, and after having pulled the old plants to pieces replant firmly, watering if the soil is at all dry. Nor ought there to be any long delay in getting out autumn-struck plants, as these also are liable to fail badly if not well established before the summer is upon them. If it is intended to intersperse Violas among variegated Pelargoniums, Iresines, and such like, mark out the spaces for these latter, and plant the Violas freely between. Beds or edgings of mixed Violas are very gorgeous, especially during the early part of the summer.

**Beet.**—The richly coloured varieties of garden Beet, than which there are none more reliable than Dell's Crimson, or more elegant than the Dracena-leaved, are very effective in the flower garden, being good substitutes for either Iresines Lindeni or Perilla nankinensis. These Beets are suitable for the second or third row in ribbon borders, and go well next to a margin of Stachys lanata in large beds. They may be raised thinly in boxes and transplanted, but succeed best when sown where they are to grow. Towards the end of April is a good time to sow the seed, and this should be done thinly in shallow previously moistened drills. Protect the seedlings from birds and slugs, and eventually thin to a distance of 9 inches apart, rather more space being allowed if the soil is somewhat strong.

**Gladioli.**—If these are kept out of the ground much longer the chances are many of them will fail to flower in time to escape destruction by early autumn frosts. If extra fine spikes are needed plant in a deep, rich, freely working, and well drained position, and if the corms can be surrounded by fresh gritty loamy compost so much the better. Whether they should be dotted thinly among other summer flowering plants of a trailing habit, notably Mignonette and Verbenas, or be planted in either groups of three, or 12 inches apart in lines 18 inches apart, must depend upon circumstances, the latter being the best arrangement if show spikes are desired. In any case bury the corms about 2 inches below the level, setting them in silver sand.

If extra early spikes of flower are wanted start the requisite number of corms singly in 4-inch pots under glass, and plant out before they become badly root-bound. Choice varieties may safely be increased by division whenever the corms show more than one crown. Start them in

boxes under glass, cut them cleanly through when the shoots are 2 inches high, return to the boxes, and finally plant out when they have started rooting afresh. Small corms obtained either by sowing seed or from the base of the older corms, may now be planted 3 inches apart in shallow sand-lined drills, 12 inches apart. In the course of two seasons they will develop with strong flowering corms.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### THE WEATHER.

FROM different parts of the country the desire for softer winds and rain is general. During the week ending on the 14th only on two mornings was the temperature above 32°. On other mornings from 5° to 6° of frost were registered, the day temperatures rising to 58° and 68°.

#### THE APIARY.

The weather has been too dry, and the air too cold for the bees to derive much benefit from the Gooseberry blossoms. The smoke that persistently hangs around and over us injuring vegetation and hindering bees is unknown in some districts, where the bees are more advanced than with us, and have done tolerably well upon the blossom. It is evident that near towns and public works bees cannot thrive so well as where the atmosphere is clear, even although flowers are as profuse in the former places as they are in the latter.

#### QUEENLESS STOCKS.

At this season of the year it sometimes happens that queens from various causes become barren, and leave the hive with the bees *en masse* as a swarm—described by some who know no better as a “hunger swarm.” The queen should be caged, and after a while destroyed, and the bees joined to another stock. I never require to examine stocks to learn their actual condition as regards foul brood, or being broodless. I can by the smell and the manner of the working of the bees diagnose all such cases. Inexperienced bee-keepers when they observe a falling off of the industry of the bees should make an inspection of the hive, and take action accordingly.

#### DRONES AND QUEENS.

These are numerous in many hives, and the bee-keeper need not be backward in taking steps to raise a few queens. The oldest queen regnant may be removed with some bees and the combs, while the remainder may be left, contracting the hive to keep it crowded for the better raising of royal cells. It must be understood that after these young queens are laying the original bees and queen, if desired, may be assisted with brood, so that there will be neither loss nor decrease in stocks by the manipulation. On the other hand, in most districts a decided gain will be effected, as the surplus queens can either be employed to advantage on the two queens in one hive principle, or take the place of the queen of other stocks that have swarmed.

#### CARNIOLAN QUEENS.

A correspondent has submitted to me a number of bees, the progeny of an imported Carniolan queen. He says, “I understand there is a difficulty in getting the pure breed now.” The bees in question were undoubtedly crosses—not merely first crosses, but a decided mongrel breed, 90 per cent. of them showing the orange bands and other characteristics of the Italian bees, there being only one greyish bee, and it did not show much if any Carniolan features. It is to be regretted that for mercenary purposes the pure, amiable, and industrious Carniolans should be destroyed. I am also in receipt of a letter from another correspondent, who asks if I observed what “Gleanings” had to say on Punics and their enemies. I did read all that my correspondent asks, and a great deal more that I should have been ashamed to write. It would be a good thing for bee-keepers if they would think and act for themselves, and take steps so that they could get everything pure and truthful, including bees and literature. Societies have only to take the proper steps, and it will be the fault of bee-keepers if they fail to bring about the needed reform.—A LANARKSHIRE BEE-KEEPER.

#### BEE KNOWLEDGE WANTED.

I SHALL be extremely obliged for very much fuller particulars as to bees, certainly Punics, and by all means straw hives; but more knowledge than this is surely needed. I know nothing. The book I obtained two or three years back, and which effectually

choked me off, was "The British Bee-keeper's Guide Book," by T. Cowan. I want to know where Punics are to be had. Do I start with a swarm or a queen? Where are those hives to be obtained? My idea of a straw hive is to smoke the bees, which I thought was brutal and obsolete.—S. J. A.

[Persons who are unacquainted with bees, and intend keeping them, should learn that from January till March there are only workers and one queen in the hive. The hive, to be profitable, should contain not fewer than 30,000 bees, with the queen healthy and prolific. After March drones may be expected. Sometimes fertile workers appear whose progeny are drones only.

Bees are subject to diseases. Foul brood is the scourge of the apiary, and is to be most dreaded; overheating or stifling the bees is the principal exciting cause. This scourge is known by the seals of the brood being concave and perforated, the larvæ brownish, and of a gluey nature, with an offensive odour. The bees should be transferred from affected to clean hives, and all their belongings disinfected. Dysentery is a preventible disease; immunity from it depends upon the preparation of the hives and food in autumn. Pure sugar is the safest food, and hives should be kept free from sudden changes of temperature, and perfectly dry, covering them with porous material and a ventilating floor; *vide* back numbers of the *Journal of Horticulture*. A cosy site is another good point, with a free flight, but no pools of water near their hives, nor vegetables such as Cabbages.

Stinging in bees depends upon their treatment. They should be frequently approached in a calm but firm manner by the owner, so that he may not be a stranger to them. When manipulating carbolic acid should be used sparingly at the entrance and on the tops of the bars, having in the hand a feather saturated with it to cause the retreat necessary for inspection. The novice should then take note of all he sees, so as to know healthy bees, combs, and to recognise queen, workers, and drones, as well as the imperfect bees that are neither one nor the other. Bee-keeping after all those things are learned or partially known is comparatively an easy task.

Straw hives are the best to start with, putting their swarms into good frame hives. The novice thus gradually learns his way, and is in a better position to manage his bees successfully than if he started with frame hives. Straw hives are the easiest to manage, but honeycomb in quantity and quality is less from them than frame hives, and is mostly run honey. When the combs are renewed annually there is less danger from foul brood. The second or after swarms having youthful queens are best adapted for stocks, and the new made combs of such hives are white, and comparatively free from drone comb.

Crossed Punics are in my experience the best bees, though the pure ones may equal them; but owing to inauspicious seasons I have not been able to test them fully. Beginners should, however, be contented to start with any bees until they know something about their working qualities, then try one variety against another, the only accurate method. Straw hives can be had from Messrs. George Neighbour & Sons, 127, High Holborn, London, and Punic bees from Mr. J. Hewitt, Cambridge Street, Sheffield.

The Lanarkshire Frame Hive is one of the oldest and best British hives. I have used it more or less since 1852, and in one or other of modified forms is becoming popular in England, America and other Continents. From its storifying nature it, to a beginner, is not quite so handy to manipulate as a more cumbersome modern hive, but in other respects eclipses them all, and when a little experienced the seeming difficulties evanesces. A beginner, might, to initiate himself, practise with a modern hive, or perhaps better with the top division (the first year) of a Lanarkshire storifying hive. I do not know who makes these specially, but Messrs. Warnock and Walker, Blantyre, occasionally make a pattern hive for beginners.—A. L. B. K.]

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Artificial Manures (H. T. H.).**—We know of no work devoted to the "mixing of artificial manures." When the different kinds required are obtained they are as easily mixed as the various ingredients are in the preparation of composts for plants.

**Daffodils from Seed (H. H.).**—We cannot better reply to your questions than in the form of a brief narrative of our own experience. We gathered ripe seeds in 1891 and sowed them early in the same autumn in boxes of free loamy soil in a Pearson's frame, in which they remained through the winter. The plants grew in those boxes till they died down, and after the small bulbs had rested for a time they were planted in the open ground early in September, 1892. Two of these seedlings flowered this spring, and many will do so next year, though we do not expect all of them to do so.

**Raising Anemones (A. M.).**—Single Anemones are readily raised from seeds, and plants raised early by sowing now commence flowering next year if grown in fertile soil. The year following they will be very fine if the tubers are not disturbed. The seed being very woolly must be separated by rubbing it with sand, and then scattered in drills about 6 inches apart and 1 inch deep, saturating them before sowing if the soil be dry. Should bright weather follow it will be advisable to shade the beds with mats or some other material, as the seed will not germinate freely; and shading is much better than watering after sowing. If the seedlings are crowded patches of them may be dug up with earth adhering to the roots, and transplanted in showery weather in summer. Fresh seed should be obtained, as the old does not germinate freely.

**Woodlice in Mushroom Bed (A. F. G.).**—If you cut Potatoes in halves and scoop out much of the inside of each portion and place them about the beds they will attract numbers of these insects, and they may be instantaneously, hence painlessly, killed by shaking them into boiling water. Boiled Potatoes enveloped in a little hay and placed in empty flower pots and these laid on their sides prove enticing to woodlice, while pieces of Parsnips boiled in an arsenical solution are deadly baits. We do not think you have much to fear from millipedes, which may be caught in a similar manner as woodlice. They have a partiality, however, for decayed matter, and do not object to a decaying Apple or bread smeared with treacle. If there are fissures at the sides of the bed the insects will congregate there, and boiling water poured in will prevent their coming out again, but it must not be sprinkled on the surface of the bed.

**Bougainvillea glabra (A. M.).**—The first mistake you appear to make is drying your plant as soon as it has ceased flowering. You should be certain that the plant has finished its growth and the wood is thoroughly ripe before the supply of water is reduced, and it should then be of the most gradual description. Pruning should not be done until the plant is resting or has been at rest a few weeks. This should consist of removing all weak growths and any portion of strong ones that are not thoroughly ripe. The weak ones may be pruned back to one eye or cut out entirely, while strong ones may be left 1 to 3 feet, according to their strength, ripeness, and requirements. If a plant is sufficiently furnished with moderately strong shoots then the whole may be pruned to one or two eyes. You should reduce the ball by one-third or half its size as soon as the plant has broken into growth, and not wait till the shoots are 6 inches long. The plant should be establishing itself by the time you repot. Does it fill the pots thoroughly with roots? if not, do not repot it annually, but merely top-dress with rich material, removing as much of the surface soil as possible. A suitable compost for this purpose is loam and one-third decayed manure. For potting we should dispense with the leaf mould and peat, using only good fibry loam, one-seventh of decayed manure, with a little sand and charcoal. You should not pinch the strong shoots; allow them to extend, for they will flower profusely if you grow the plant fully exposed to the sun. Thin the weak shoots so as to give those remaining room to increase in strength. More flowers are produced by a few good growths than from

twice the number of weak shoots. This plant will do in the same pot for a number of years, provided it is top-dressed when it breaks into growth and judiciously supplied with liquid manure during the season of growth. Be careful in watering, and place the plant for a time in a warmer house.

**Repotting Ericas** (W. W.).—The advice not to attempt to liberate the roots from the soil when repotting applies equally to summer and winter-flowering Heaths. A little root-disturbance by removing the crocks, also by clearing away a portion of the loose surface soil, is all that should be permitted in transferring Ericas from small into larger pots, and even in those respects the work of liberating the roots must be done with great care and much caution. In potting these plants it is important that both the soil in which the roots are established, and that to be used is healthily moist. If either too wet or too dry success will not follow. The new soil must also be pressed as firmly round the roots as the old is, a blunted stick being used for that purpose. Many Ericas are spoiled by potting them too lightly and disturbing the roots needlessly.

**Daisies on Lawns** (H. B.).—The presence of Daisies in lawns is nearly always indicative of poverty of soil. An excellent dressing is a mixture of superphosphate of lime and nitrate of soda, two-thirds of the former and one-third of the latter applied during showery weather at the rate of 2 ozs. per square yard at intervals of a fortnight. If dry weather prevails it is a good plan to well water the lawn before applying the fertilisers, and then again afterwards to convey their virtues to the roots of the grass. Mixtures of guano and salt and soot and salt also act beneficially, so also do bonemeal and wood ashes. We mention these different ingredients in order that you may use what is the most convenient or readily obtainable. The most effectual mode of destroying Dandelions and Plantains is to drop a little sulphuric acid into the heart of each plant, as was recently recommended in these columns. Some persons have found lawn sand effectual in destroying Daisies.

**Azaleas and Heaths Unhealthy** (J. H. C.).—Azaleas well managed flower profusely every year. They require to be firmly potted in good peat soil with a little leaf mould and sand intermixed and very carefully watered, neglect or mistakes in this respect quite nullifying everything else that may be done for them. If once the soil gets quite dry the hair-like roots shrivel, the leaves fall from the plants, and flowers consequently cannot be produced. A greenhouse temperature suffices, a little extra heat in the spring when growth commences, and copious syringing being advantageous. Plants that are very unhealthy are difficult to restore. Close pruning will not benefit them, but removing a good portion of the old soil and repotting in fresh of the nature indicated, using pots as small as possible, and pressing the soil very firmly, always keeping it moist but never saturated, placing the plants in a warm greenhouse or vinery, syringing them at the least twice a day, may possibly induce them to commence fresh growth. That is the only way in which they can be improved. Heaths are perhaps still more difficult to renovate. They must not be pruned below the foliage or they will die, and the general treatment as advised for Azaleas may be adopted, except that they will be better in a cool frame than a warm house. Only experienced cultivators can grow these plants satisfactorily.

**Epiphyllum Culture** (Amateur).—Encouraging free growth in the early part of the season under the influence of heat and moisture, and ripening it subsequently by full exposure to the sun, with reduced moisture, are the chief essentials in the cultivation of these plants. Possibly yours may not need repotting, and if not some of the old soil may be taken out and fresh added as a thick top-dropping. A successful cultivator has written as follows about these plants:—"During the growing season they delight in a warm close atmosphere, where they can be shaded from strong sun. They must also be liberally supplied with water. When the soil is allowed to become dry their fine silk-like roots quickly perish. Many failures have arisen from the poor soil given to the plants. A very suitable compost is rich fibry loam, one-fourth leaf mould, one-seventh of cow manure, and a liberal dash of coarse sand. A little charcoal in the soil proves beneficial if the loam is inclined to be heavy. When the pots are full of roots manure applied to the surface of the soil will keep the roots in activity and assist the plants wonderfully. Directly growth has been completed the stems should be ripened by gradual exposure to light and a cooler atmosphere. This is essential if they are to flower profusely; they will not flower on growths that are soft and unripened. The advance of these plants can be prevented at almost any time after a good growth has been developed—that is, say towards the middle of September. Fatal results often attend the resting of Epiphyllums, which is due to the want of knowledge of their cultural requirements. The plants must not be removed from a close warm house to a cold one, or they suffer severely. They should be placed in a house 10° lower than the one in which they have been growing, less moisture should be given and more light. This is sufficient to bring growth to a standstill and ripen it thoroughly. Failure results very often during the ripening or resting period from subjecting the plants to a roasting system of culture. How many may have been ruined through being kept so dry at their roots until their branches shrivel! This treatment destroys roots, and the greater portion of the moisture stored in their fleshy growth is evaporated. They require a drier atmosphere than the ordinary stove, and a temperature of 50°, with just sufficient water at their roots to keep the branches in a fresh plump condition. After they are once hardened and ripened they will bear cooler treatment for a time, and may be safely kept in a cool house. If the soil is wet about the roots while the plants are in a cold house they are certain to fail."

**Leaf-mining Insects on Marguerites** (L. S.).—Your plants are attacked by a leaf-mining insect of a similar nature to those that are so destructive to Celery, Parsnips, and other plants. Eggs are deposited by a small fly which hatch into maggots, these eating out the substance of the leaves and ruining the plants. So destructive is the Marguerite pest that in many places the plants cannot be grown at all. We can only suggest one remedy. We should like you to try the effects of petroleum prepared as follows:—Boil 2 ozs. of softsoap and a lump of soda the size of a walnut in a gallon of water, stirring in briskly half a wineglassful of ordinary petroleum that is burned in lamps. When this is cool stir again and dip a plant in it, or syringe it well, but keep it out of the sun until it is dry. If this does not injure the plant add twice the quantity of petroleum, and try the mixture on another plant. So continue the experiment of increasing the petroleum so long as the increased strength does not injure the leaves, and we think it possible you may destroy the maggots without spoiling the plants.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (R. C.).—*Primula farinosa*; *Omphalodes verna*. (C. B.).—*Prunus* (*Cerasus*) *padus*, the Bird Cherry. (C. A. L.).—*Kerria japonica flore-pleno*. (A. M.).—*Primula japonica*. (F. D. Bedding plants in variety.

## LIVE STOCK—SELECTION AND BREEDING.

ONE of the most important lessons of adversity taught by hard times is the true value of the selection, breeding, and careful management of all live stock on a farm. More and more attention is given to this by all thoughtful farmers, and the paper bearing on this subject, which Mr. J. Kersley Fowler read recently at the Farmers' Club, contained such a mass of useful information as will exercise much influence upon the minds and efforts of really earnest workers in the good cause of rendering farm animals really valuable as a source of profit. The days of mongrels with no points of excellence are surely numbered, for the fact of well-bred, well-fed beasts proving so profitable in such a year of falling prices, as 1892 undoubtedly was, must carry with it conviction that only by careful selection and breeding can we hold our own now and in future under ever increasing foreign competition. In accepting and acting upon this axiom let it not be forgotten that really good work in breeding does not involve the use of pure pedigree animals on both sides, and we entirely agree with Mr. Fowler that "The thoroughbred should be on one side or the other, and it is perfectly wonderful how quickly a really fine flock of sheep or a good herd of cattle can be produced, and eventually maintained. Many a great line of grand animals can be produced by this system, and in the course of time the flock or herd is enabled to take rank as pure-bred animals."

Plenty of evidence in support of Mr. Fowler's views is forthcoming from other breeders of note. Mr. John Treadwell of Upper Winchendon gives instances of improvement in cattle, sheep, and pigs. The evidence of such famous breeders as Mr. Spencer of Holywell Manor; Mr. Duckham of Holmer, Hereford; and Mr. C. Barnes of Solesbridge, near Rickmansworth, might also be adduced if necessary. But our especial object is sufficiently apparent in calling attention now to the real value of a pedigree male animal of fine form and sound constitution for the profitable production of home reared beef, mutton or pork.

For milk also selection is of even greater importance, because of the low general average of milk yield, and the great range of milk yield from an ordinary herd of cows where any heifer is thought good enough for milking, up to the Duke of Westminster's two Cheshire herds, or others where due attention is given to selection and breeding. It is not a question of the largest animal. Take for example the marvellous little Kerry, "Red Rose," in the Kidmore Grange herd. Mr. Charles Simmons says she is not much higher than a large donkey, weighing, he thinks, about 9 cwt. She calved the last week in March, 1892, and from April 1st of that year to the same date this year she gave 4 tons 9 cwt. 3 qrs. 20 lbs. of milk, the milk being weighed morning and evening as soon as taken from her. Take also that other wonder of the same breed, "Babraham Belle," belonging to Mr. Adeane, weighing only 889 lbs., yet at the Warwick Show last year she gave from a morning and evening milking 51 lbs., or 5 gallons of milk, yielding 4 per cent. of butter fat. Among the Duke of Westminster's cross-bred Shorthorns five cows gave over a thousand gallons apiece last year, one of them actually yielding the phenomenal quantity of 1338 gallons in forty nine weeks. Every bull calf from such cows should be reared, as they must be invaluable in breeding for milk.

## WORK ON THE HOME FARM.

Good sound Oats are the only home-grown grain now being sold at a profit. The straw has been even more than usually useful for fodder, the grain used whole, kibbled, or as meal, is alike useful, and it is easily

understood how, in a review of last year, Oats were termed a most satisfactory crop. We mention this because, if rain does not soon come there must be some exceptionally late sowing, more particularly on strong clays which were ploughed up wet and are now absolutely unworkable, and Oats will be the crop to afford a fair yield of straw and grain if sowing has to be done in May.

In every locality where three or four months of free growth after the 1st of June are a certainty, we strongly advise keeping a few acres of land in reserve for an abundant supply of green Maize in September and October. The whole of it should be used before severe frost sets in; the possibility of early frost must, therefore, be taken into account in connection with this crop. If even frosts should render its use necessary in August, it would answer to grow some. The minimum yield per acre under such early use would be from 7 to 10 tons, the maximum yield from further fuller development rising to 30 tons per acre. For all farm animals it proves a great boon in late summer and early autumn always; with parched pasture bare of food as it is sometimes then, this grand summer fodder plant is invaluable.

In southern counties Rye, from 1 to 2 feet in height, is now being folded or mown, and Maize follows such a crop well, especially if sheep have been folded upon it. To have growth of full vigour from Maize we must have rich land; there is no better crop for a sewage farm, except perhaps Italian Rye Grass. Failing the sewage, we must manure heavily with whatever is available. Among other things, peat moss litter, and sawdust from a stable, are both excellent. Near large towns one or both may be had, and the ordinary stable manure, which under the existing sanitary laws has to be removed daily, will do also, provided there is enough of it. Chemical manures may, of course, be turned to, and if they are used we would have at least 2 cwt. of nitrate of soda per acre. Condition of soil must be the planter's guide in this matter, and we can only indicate generally what should be done.

## OUR LETTER BOX.

**Pasture Ready for Grazing (C. O. E.).**—The pasture which was mentioned as "so forward in growth that cows go out four or five weeks sooner than was possible last year" is in Surrey. You say that in the Midlands there is not a blade of grass on land of this description, and generally you are right, but we have seen pasture recently at Melbourne, in Derbyshire, and Ashby Folville, in Leicestershire, with a really good bite of young succulent herbage upon it. We know plenty of bare pasture now in both those counties, but the bareness is not entirely owing to a want of rain, though this of course has a retarding effect. Poverty of soil and keeping stock out all winter are the dominant reasons why pastures generally in the Midlands and elsewhere are brown and bare in winter, and backward in spring growth. You have only to make sure of perfect drainage and sustained fertility of a sufficiently high standard to have early growth, if only you withdraw cows and store cattle entirely from pasture in October. Often have we told how slow growth in spring is on poor land, how brisk on rich land; how it marks the difference between the cultivation and neglect of pasture especially, but also on other kinds of crops. Market gardeners know how important rich land is for securing early crops. We have seen a plantation of Cabbages raised from seeds out of the same bag, sown at the same time, and the plants put out the same day, but a portion of the stretch of land had been exhausted by a previous (seeding) crop. The Cabbages on this portion were fully three weeks later than those on the richer land, and not half so good. The former, in fact, represented a distinctly profitable crop, the latter as distinctly the reverse. Impoverished land would soon starve market gardeners out of their holdings, as has been the case with many, also, we fear, some farmers. Only rich land pays by affording early, full, succulent crops.

## REMARKS.

- 9th.—Bright sunny day; a little fog in evening.  
 10th.—Almost cloudless throughout.  
 11th.—Overcast till 2 P.M.; frequent faint sunshine after.  
 12th.—Alternate cloud and sunshine, the cloud rather preponderating.  
 13th.—Overcast early, with slight drizzle; generally sunny after 10 A.M.  
 14th.—Foggy early; bright sunshine from 10 A.M.  
 15th.—Bright sunshine throughout.

Another week of absolute drought, Saturday being the twenty-ninth consecutive day with no measurable fall of rain; a period which is longer than any other in my record, which extends back to 1857. As the rain in the middle of March was quite trifling, we have practically (though not strictly) had no rain for seven weeks, as we must go back to March 1st for a record of a tenth of an inch.—G. J. SIMONS.

"**F**ORTY-THREE days without a drop of rain" is Mr. E. Molyneux's record of the weather at Swanmore, a fact, he goes on to say, "unprecedented in the memory of the oldest inhabitant at this season of the year." It is indeed remarkable, and it would be interesting to know of records, if any, of still longer terms during which not a drop of rain was found in the gauge. This abnormal period of drought is causing many persons to exercise their memories in finding parallels to it in past times. I have no recollection of forty-three consecutive rainless days, but I have a very vivid recollection indeed of what may be termed a fight with drought more serious than Mr. Molyneux has experienced this year.

Memory takes me back twenty-five years, perhaps about the time when your correspondent was learning to spell "Chrysanthemums" preparatory to making cuttings and growing the plants—an art of which he is now a past master. The drought in 1868 that was so exhausting was in summer, and the brunt of it was borne on the limestone ridges in the eastern counties. I have been asked if the spring of that year was a dry one. It was not a wet one by any means. The whole year was dry, the rainfall only being about  $16\frac{1}{2}$  inches, and from the middle of February to the middle of August we had not, speaking from memory, 6 inches of rain. Gardens were, generally speaking, destitute of vegetables, pastures were "burnt up," trees drooping and shedding their leaves, flocks and herds languishing, the harvest completed in July, large tracts of country like a desert, and the "hill tribes" wended their way to the valleys for miles with water carts, which traversed the roads "boot deep" in white dust night and day. Gardeners, farmers, and others who went through the ordeal of that exhausting time will be ardent in their hope that the present abnormal drought is not the precursor of a summer like 1868.

Not having access to my weather records, carefully entered at the time, I have examined those in the *Journal of Horticulture* respecting the London rainfall during the spring of the year named. I find the amounts for February, March, and to the 21st of April 0.81 inch, 0.54 inch, and 0.57 inch respectively, or a total for the three months of 1.92 inch. During that period rain fell on eighteen days, and there was no measurable quantity (less than 0.01) on sixty-two days. How does this compare with the results at Swanmore and elsewhere from February 1st to April 21st this year?

Passing onwards in 1868, let us see what followed the above total of less than 2 inches, from February 1st to April 21st. In the last week of April nearly half an inch fell—0.48 inch. In May the quantity measured was 1.05 inch, June 0.33 inch, and July 1.32 inch—a total for those three months of 2.70 inches. This fell on sixteen days, no rain falling on seventy-five days. What may be described as the drought term of 1868 commenced on February 1st and ended on August 10th, and from the beginning of the year to that date the rainfall was only 5.63 inches, and it would be less rather than more along the east coast. During the whole of that time there were only three good showers—namely, of 0.70 inch the third week in January, 0.90 inch the last week in May, and 0.98 inch the second week in July, and only on one other occasion did the rainfall equal 0.50 inch. During the whole

period of 223 days rain only fell, mostly in very small quantities, on forty-nine days. This collation may be interesting for comparison, and may perhaps induce meteorological observers to look over their records for notable periods of drought, and the effect on vegetation.

In 1868 no serious difficulty was experienced till May. Then it was the earth appeared to be exhausted of its moisture by trees and crops. In my case fortunately two courses had been adopted, and both were found beneficial under the circumstances. Having in view the generally light rainfall of the district and non-retentive soil, all garden crops to which the practice was applicable were sown and planted in hollows, so that water could be conducted to the roots. Heavy supplies were given once a week, mulching being also resorted to. Crops on the level could not be usefully watered, and those in the trenches were kept growing by the applications. The great affinity of salt for moisture was also recognised, in fact demonstrated. In the garden it had been the custom to salt the Asparagus beds freely for years, and the soil was so impregnated with the mineral that weeds could not grow in the beds, but Asparagus did famously. The beds were isolated—that is, at the least 10 yards apart, and other crops grown between them. In the hot weather the salted soil was moist when the spaces between the beds were as dry as a desert. It was also observed that a portion of salt having been unwittingly cast beyond the beds in its application to them had a distinctly beneficial effect on the rows of intercrops nearest the beds. This led to the use of salt generally, and it was applied freely, almost lavishly, in garden, park, and fields, during two years prior to the "big" drought. The land was well charged when this set in, and made the best of what little rain there was, as well as the dew when there was any. The result was very striking—a green park, fields, and garden long after all the land around was parched. Deep culture was the rule where practicable, and hoes by hand and horse kept at work to produce a dusty surface and prevent fissures where mulching could not be done. An inch or two of dust acts like a blanket in arresting evaporation from the earth. By such methods the losses resulting from drought in a memorable year were minimised, and salt played an important part in the work.

The heat during the spring of 1868 did not equal that of the present year, when the maximum readings of the thermometer have been abnormally high, exceeding  $82^{\circ}$  in the shade in several places during the past week. As a result of the high temperature, Horse Chestnuts, Laburnums, Wistarias, Lilacs, and even Hawthorns are in full bloom in the southern suburbs of London. The expansion of the latter in April is a rare occurrence, and the blossoming is more often deferred till June. Weather prophets are apprising us of wet weather in July, August, and September, but their prescience is somewhat discounted by their having omitted to inform us of the present extraordinary heat and drought. Speaking of weather forecasts, I have come across the following narrative in a daily paper, the "Morning," of how they are made:—

"In a lofty building in Victoria Street, London, where not only does the clerk of the weather exist in the flesh, but the weather itself can be seen in all stages of development. Here is what Mr. Gaster, the head of the Forecast and Report Department, had to say concerning the methods by which details regarding the weather are compiled and sent broadcast for the public benefit:—

"All barometrical returns (many of them made from the tops of mountains or very high observatories) are corrected to  $32^{\circ}$  Fahr. and the mean sea level. This system holds good throughout the world, and works very well. The barometer is the most susceptible of instruments, and the most infinitesimal variations in the density of the air will send the mercury "up" or "down." The thermometer is also an important factor in considering weather reports. The Fahrenheit thermometer, which is in use throughout the United Kingdom, is discounted in its usefulness by the meaningless method of counting the degrees. It is purely arbitrary to make  $32^{\circ}$  stand for freezing point and  $212^{\circ}$  for boiling

point. The Reaumur is no better, and is now out of use except in Russia and some parts of Germany. The most practical gauge of temperature is the Centigrade thermometer;  $0^{\circ}$  makes the freezing point, and  $100^{\circ}$  the boiling. Calculations on the decimal system are always easy and satisfactory. A wet bulb thermometer is necessary for showing the amount of moisture in the air.

#### FORECASTS ARE MADE

by comparing the returns of barometrical pressure at the different stations, always taking into consideration the climatic conditions. We then find out whether or no an area of low pressure—commonly called a depression or cyclone—is approaching, and bringing with it rain and squalls. In the summer a depression brings cold and wet; in the winter, as a rule, it is accompanied by muggy damp weather. The winds in this area circulate against the sun. The exact opposite ensues when an anti-cyclone arrives on our shores. In the winter the dead calm of an anti-cyclone induces fog and frost, but in summer it brings heat and clear fine days. In spite of every care, however, and the most minute observations, it is not always easy to forecast the line that one of the areas—more particularly the cyclones—will take.

“As cyclones move so fast, we have a very complete system of issuing storm warnings. A whole coast can be warned in less than an hour. We wire the names of certain centres, and the warning to be issued, to the head telegraph office. They send our message to the towns indicated, and from them again the warning is flashed to all the small stations. Our account with the telegraph department is about £2500 a year. From Norway and Sweden messages are sent free as far as our shores, then we have to pay. From Russia and Turkey we receive reports by letter, as wiring them would be too heavy an expense. We have a Government grant of £14,000 a year, and about 300 subscribers who receive all the reports that we publish. Our reports for the newspapers, which are compiled from the telegrams we receive at 6 P.M., are sent to them gratis.

#### WEATHER RECORDS.

“All documents received by us relating to the weather are most carefully preserved for a long period of years. Weather records are in great demand by agriculturists, by makers of charts, and by the legal profession. At least four or five times a year we are called upon to produce evidence in a court of law concerning weather. In Board of Trade cases proofs are often demanded from us respecting gales or fogs. Farmers often consult us with respect to the past records of their own particular part of the country. A man may drain his fields or change the nature of his crops on the strength of what he hears from us. We also often have inquiries from people who wish to discover a suitable climate for invalid friends. Indeed, there are few walks or incidents in life in which the weather does not at some time or another play a prominent part.”

The above information is not uninteresting at the present time. It represents what is being done with the aid of the best appliances, but these do not enable the authorities to indulge in prophetic utterances many hours in advance of expected issues.  
—AN OLD GARDENER.

## ASPARAGUS.

### PLANTING AND SUMMER TREATMENT.

I THINK this delicious edible merits the unenviable distinction of being less generally cultivated than any other vegetable which is so highly esteemed, and yet so easily grown. There is no valid reason why Asparagus should not be as much grown as Green Peas, for it is an undoubted fact that during its season it occupies the same position on some tables as Peas do a few weeks later. But there are tens of thousands who seldom, if ever, taste Asparagus, and many more who do not get half enough. When we look at these facts in a thoughtful manner the question naturally arises, What have been the chief causes which have led to this state of affairs? They may, I think, be traced to complicated methods of culture, and the inherent inclination to plant only sparingly those crops which do not give a full return the first season. Fortunately, we have now found out that splendid results may be obtained by growing Asparagus in a simple and rational manner, and that those crops which give the quickest returns are not always the most satisfactory or profitable either to the professional gardener, the amateur, or the farmer, and each of these classes will do well in the future to extend the space devoted to Asparagus culture, if a beginning has already been made, or to begin at once where it has not yet been attempted.

The soil best suited to this vegetable is a sandy loam, made rich by heavy dressings of well-decayed manure. Soils answering

to this description abound in many parts of the country, and with a fair amount of attention these may be made to produce excellent and profitable crops of Asparagus. No time of the year is more suitable for planting than during the present month, when growth has commenced and the roots are in such a condition as to enable them to work at once into the surrounding soil. When very early planting is practised the natural result of this is that many of the roots die, and others start very weakly.

Assuming that the ground has been recently trenched or double dug and well manured no further preparation will be necessary, but if ordinary digging only has been resorted to a little extra attention ought to be given before planting. A plan which answers admirably is the following. Take out a trench two spits wide, lay the soil on a side, then place 6 inches of thoroughly decayed manure on the bottom of this trench, and dig another spit deep, taking care to thoroughly incorporate the manure with the soil as the work proceeds. Part of the top soil should then be returned to the trench, and be trodden moderately firm, leaving it in the form of a slight ridge along the centre, the top of this ridge being about 4 inches below the ground level. In preparing the trench for planting on ground which has been manured and deeply dug all that is necessary is to take out a trench the width of a spade, leaving a slight ridge in the centre, this also being 4 inches below the ground level; in either case these trenches will then be ready for planting.

Much diversity of opinion exists among cultivators as to the distance apart at which the roots should be set. For ordinary purposes I prefer to have the rows 2 feet apart, the plants being disposed 18 inches from each other. This admits large well-growing clumps to develop good growth, without which fine heads are not obtainable. Where extra large heads are required for exhibition purposes, the clumps should be set 3 feet apart each way. August sown Lettuce may be planted thinly between the rows. Two-year-old clumps of Asparagus are the best for planting. These should be carefully lifted so as to preserve the roots without breakage as much as possible. If not planted immediately after lifting the roots ought to be covered with damp moss or soil, and be given a good soaking with water. It is all-important that this point be attended to, for under such conditions the check attendant upon transplanting is scarcely perceptible, while if it is neglected, partial, if not total failure, will be the result. Before planting a line should be stretched along the centre of the ridge, supporting it at intervals with forked sticks to keep it clear of the soil, so that the crown of the roots may be placed exactly under the line, and the roots be spread out on each side. Especial care should be taken to spread them out to their full length, so as to enable them to work freely among the soil. As the planting proceeds, a little of the finer portions of the soil ought to be placed over the roots with a trowel. As each row is planted and the line removed, the trench should be filled in and the soil made level with a rake, but, except in the case of very light soils, treading should not be done. A thorough watering through a coarse rose ought then to be given, and when the whole is completed, 2 inches of well-rotted manure may with advantage be placed over the whole surface of the bed.

In low damp positions, or on clayey soils, raised beds are necessary. These may be formed by taking out the soil to a depth of 2 feet and stirring the subsoil to render drainage efficient. Over this 9 inches of stubble should be placed, this being covered with a layer of rough manure. Large quantities of burnt refuse, and a fair amount of manure should then be mixed with the soil as it is returned to the bed, bringing it up to 6 inches above the ground level before the ridges are formed for the roots. After these have been placed in position it is a great advantage to cover them with a little soil of a finer nature, such as old potting soil, before finishing off with the natural soil. In clayey soils the crowns should be covered to a depth of 2 inches only. Beds 5 feet in width will accommodate three rows of plants. They should be set 18 inches apart in the rows. Alleys 2 feet in width ought to be provided between the beds, and a strong stake driven into the ground at the corner of each bed.

Should the weather prove dry water must be regularly supplied till the plants are well established. If liquid manure is obtainable an occasional application of it may with advantage be given throughout the summer months; failing this, nitrate of soda applied once a fortnight (in showery weather if possible), at the rate of  $1\frac{1}{2}$  oz. per square yard, or a moderate sprinkling of salt will be found very beneficial. If the young shoots are not cut the year after planting, cutting may commence the following season; but it ought not to be very severe till the third year, and throughout each growing season high feeding must be the order of the day if superior produce is looked for. With these essentials well attended to a bed will continue in full bearing half a century, so that the slight outlay and waiting for a crop at the outset is overwhelmingly repaid. Throughout the growing season

all beds should be kept free from weeds, but the hoe must on no account be utilised to perform the work until growth has become well advanced, otherwise many promising young shoots beneath the soil will be destroyed. Extra strong shoots need supporting with stakes to prevent injury by wind, for the chief aim of the cultivator should be to promote vigorous, healthy growths, and preserve them intact till natural decay takes place. He may then look confidently forward to reap a good harvest of tender young shoots the following spring.

It is not often that growers in this country adopt the practice of earthing up the shoots as soon as they are visible, though they undoubtedly would do if appearance were the only consideration, because by that method long, straight, white stems with short green tips, are produced. These look extremely inviting in the shop windows, but unfortunately only the green part is eatable, but by allowing the heads to grow 3 or 4 inches above the soil, and then cutting the stems at about the same distance beneath, we secure a maximum amount of delicious food, with a minimum length of useless stem. Cutting ought to cease about the end of June each year.—G. W.

#### DECIDUOUS MAGNOLIAS.

ALTHOUGH I fully appreciate the great beauty of these fine shrubs when grown as bushes on the lines indicated by "E. M." (page 315), I must also add that the method of culture there given is not well suited to plants growing in the midlands and the north as to those in the sunny south.

When living in a Kentish garden I often admired several fine plants of *M. conspicua*. The flowers generally escaped injury from frost growing in a mixed shrubbery. I find, however, that the case is quite different at Warwick, for during the last two seasons flowers of this variety have been totally destroyed by frost where left unprotected, although the trees are trained against a very high thick wall, and those branches which protruded the farthest from it suffered the most. I think, therefore, it is much more satisfactory to keep the shoots trained in close enough to receive the full benefit of the protection afforded by the wall than to let them ramble more freely or grow them in shrubberies, and have the flowers destroyed year after year. The plants here are trained to grey sandstone walls, which form a far better background for the flowers than "dull red bricks," though the latter is scarcely a serious objection, for so profuse is the flowering of this *Magnolia* that scarcely any of the background is visible.

The only variety I find suitable for bush culture in this district is *Stellata*, which is a very compact grower, and produces comparatively small but extremely pretty white flowers; these open fully three weeks later than those of *conspicua*, and on that account generally escaped injury from frost. *M. purpurea* *Lenneana* is a very desirable variety to grow, as it bears very large flowers, from 6 to 8 inches across, the colour of the petals being crimson, purple on the outside, and pale pink inside. It flowers a fortnight later than *conspicua*, and is in every respect a grand variety.—H. DUNKIN.

#### APRIL FLOWERING SHRUBS.

I DO not think in gardens generally sufficient use is made of the wealth of flowering trees and shrubs available during the spring months. The rage appears to favour evergreens too much in planting new and renovating old gardens. These are all very well during the winter months, but there is still no reason why a more extended use of the flowering trees and shrubs cannot be made.

The majority of these plants are not fastidious in the matter of soil, many will flourish in that of the poorest character. The main point to observe to attain success is a rational mode of planting them and pruning afterwards. Those of the deciduous order should have what pruning they require done directly the flowering season is past, whereas many persons put this off until the winter or even the spring months, and of course cut away a whole host of flower buds. For instance, who with even an average knowledge of the requirements of hardy shrubs would think of pruning Guelder Roses or even Lilacs during March? Yet we hear of this being done in the usual spring digging of the shrubberies. The main object in pruning flowering trees and shrubs is to preserve some uniformity in shape and to prevent each rambling beyond a prescribed limit, and at the same time to have the growth in such a state of maturity that the fullest amount of flower is obtained from each that is possible.

I have jotted down a list of shrubs that are now in flower here, and this is but a small garden in the extent of shrub accommodation. This list will serve to show what can be done towards beautifying the outside garden during the month of April. *Kerria japonica* fl. pl., Ghent Azaleas, *Rhododendrons*, *Berberis Darwinii*, *B. dulcis*, *B. vulgaris*, *B. aquifolium*, Purple Barberry (*B. purpurea*), *Choisya ternata*, *Magnolia purpurea*, *M. Soulangeana*, *Spiræa prunifolia* fl. pl., *Akebia quinata*, *Forsythia viridissima*, *Exochorda grandiflora*, *Amelanchier florida*, *Amygdalus communis*, *A. persica* fl. pl., *Pyrus japonica*, *P. prunifolia* (Siberian Crab), *P. malus baccata*, *P. m. floribunda*, *P. spectabilis rosea*, *Cercis siliquastrum* (Judas Tree), double flowering Cherry, *Lilac vulgaris*, Charles X., Persian, *Lonicera tatarica*, *Erica codonodes*, *Vaccinium*, Yellow Spanish Broom, *Laurustinus*, *Deutzia gracilis*, *Ribes sanguinea*, *Clematis montana*, and *Wistaria sinensis*.—E. MOLYNEUX, *Swanmore*.

#### ANGRÆCUM SANDERIANUM AND A. CITRATUM.

OF the smaller-flowered section of *Angræcums* the above species should, I think, be found in every collection. When well flowered they are charming, and are much admired. With proper culture they will flower annually. Both may be grown in small teak baskets in fresh sphagnum, some lumps of charcoal, and a little peat fibre, and suspended close to the roof. They enjoy a hot moist atmosphere all the year round. During the growing period they require liberal supplies of water, but greatly reduced during the winter months, and they should be shaded from very bright sunshine.

*A. Sanderianum* has pure white flowers, with a spur 3 inches long, exhaling a powerful fragrance, the peculiarity of which I have often noticed that in the evening twilight it is the most pronounced. *A. citratum* has creamy white flowers, with a short spur, somewhat thickened towards the extremity, regularly set on graceful arching scapes, which are admirably adapted for making ladies' sprays.—W. H. S., *Stourbridge*.

#### CALYPSO BOREALIS.

AMONGST the exhibits before the Orchid Committee of the R.H.S. on March 28th was a basket of British and other Orchids from H. J. Elwes, Esq., Andoversford, amongst the plants being *Calypso borealis*, for which a botanical certificate was awarded. It is not a British plant as some may have thought, nor is it new, having been introduced from North America as far back as 1820. It is extremely distinct and attractive, having a profusion of brownish red flowers, and growing barely 6 inches high. It is a terrestrial Orchid, and does best in sandy loam and peat. Doubt-

FIG. 62.—CALYPSO BOREALIS.

less it could be established in a suitable medium within the shelter of a wall, but it is best grown in a pot and kept in an unheated frame or pit. Fig. 62 represents it.

#### PHAJUS × GRAVESII.

This new hybrid, says a correspondent in the "Garden and Forest," is the result of cross between *Phajus Wallichii* and *P. grandifolius*. The seed was sown July 6th, 1889, came up December 1st, 1890, and bloomed February 12th, 1893. The general habit of growth and shape of spike and flower is that of the seed parent; the flower is 5 inches across; sepals and petals

cinnamon colour, with white reverses; lip pink-rose on front, with a white pencil mark extending to apex, the part enfolding the column white, stained with yellow near the base; column pure white. The name is complimentary to H. Graves, Esq., of Orange, New Jersey.

### STRAWBERRIES FOR FORCING.

FOR the information of those who have not been successful in growing Strawberries in pots, I will give a few hints which may be useful in future attempts, also to young gardeners. In the first place it is essential to have young beds, I mean beds made the previous summer of strong runners. These will have made strong crowns by the following spring, and will produce the earliest runners.

Layering should commence in May as soon as good runners can be procured. They ought to be placed into 60-size pots, and secured by small pegs, which can always be obtained from old disused brooms. The leader and side runners must be pinched off, so that the whole vigour may be concentrated to the main runners retained. The pots should be stood on pieces of slate, so as to prevent worms getting in the soil. Watering at this stage must be well attended to, or a season's labour will be thrown away should the plants be allowed to become dry and parched. It is an advantage to water with a moderate rose, as the foliage is thus thoroughly wetted, and so kept free from red spider.

When the runners have become root-bound they should be shifted into larger pots; those required for early work, such as Noble, Vicomtesse Hericart de Thury or Keens' Seedling put into 6-inch pots. This will be found to be an advantage when forcing, as the roots are more readily warmed than when placed into larger sizes. The later varieties, such as La Grosse Sucrée, James Veitch, President, or Sir Joseph Paxton (these I have placed in the order of ripening), should be placed in 7-inch pots. Use a compost of one-half decayed turfy loam, quarter leaf soil, and quarter stable manure, not too decomposed, as the strength will be gone, but prepared as if for a Mushroom bed. To this should be added a fair sprinkling of soot, bone dust, and a little lime, the whole being thoroughly mixed and allowed to remain in a heap a month previous to being used. This allows the loam to become impregnated with the various manures.

After being potted the plants should, if possible, be stood in lines on a walk fully exposed to the sun. The runners and weeds must be removed, and watering duly observed. When the pots are full of roots liquid manure should be supplied twice a week; the drainings from the stable form an excellent manure, and can be used mixed with water about the colour of brown brandy. There remains one more serious chance of failure, and this I will explain. When the crown has almost finished its work it will put out at the axil of the leaves other breaks. These should be pinched or rubbed out, for if allowed to remain will form into other crowns, which weaken and draw from the main crown.

Another cause of failure is undue forcing; for instance, it would be absurd to expect Sir Joseph Paxton or President to fruit satisfactorily early in the spring, these being used, as a rule, for the last batch. These varieties will not force as readily as Noble, Vicomtesse Hericart de Thury, or Keens' Seedling. I should strongly recommend those who may not know the merits of each or any individual variety to obtain the advice of someone who is in a position to tell them rather than follow their own ideas.—H. P., *The Knoll Gardens, Wimborne.*

### GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ON Friday evening last a very successful meeting was held at the Redland Park Hall, Bristol, for the purpose of advocating the claims of the Gardeners' Royal Benevolent Institution, under the presidency of J. H. Lockley, Esq., late High Sheriff for the county. It was announced that Mr. Harry J. Veitch, Treasurer of the Institution, who had been announced to give an address, was unable to be present through pressure of business.

The Chairman, in his opening remarks, said Mr. Veitch had shown his sympathy with the Society in a practical way, and they had his wishes for a successful meeting. He pointed out the advantages offered by the Society in its provisions for old age pensions. He said he admired the thrifty man who endeavoured to make provision for old age without assistance, although, of course, they knew there were many people who had not really the power to set aside sufficient to procure for them at an advanced stage of life an old age pension. The Gardeners' Institution stepped in and did a good work. The sum of £20 a year, at which old age pensions were fixed, meant 8s. a week, and the majority of societies in Bristol, some of which had been in existence 150 years, rarely apportioned to a man or woman who had reached the eligible age a larger amount than this. If this Society could be induced to open a

branch in Bristol and the neighbourhood, he felt quite sure of this, that by the gardeners themselves showing they had an interest in the Institution, which was established purely for themselves, there would be no lack of outside interest to help them.

Mr. George J. Ingram, Secretary, followed with an exhaustive address on the principles, objects, and needs of the Institution, after which, on the motion of T. Walls, Esq., Town Councillor, seconded by Dr. Shaw, it was unanimously resolved that "An auxiliary of the Gardeners' Royal Benevolent Institution for Bristol, Bath, and neighbourhood be formed, and is hereby inaugurated at this meeting."

Messrs. Webley, Garaway, Vallance, and Parsons also addressed the meeting, and the Chairman consented to become President of the local auxiliary, and announced his intention of becoming a life member and an annual subscriber to its funds. Many other annual subscribers were also announced.

Hearty votes of thanks to Mr. George J. Ingram for his address, and to the Chairman for presiding, brought the meeting to a close.

### SUMMER PRUNING VINES—AN OBJECT LESSON.

MR. STEPHEN CASTLE'S practical and interesting remarks on the above subject in the *Journal of Horticulture* for April 6th (page 281) come at a very opportune time. There can be no two opinions as to the advantage and ultimate good results traceable to the practice of the early disbudding of Vines, removal of superfluous bunches, and the prompt thinning of the berries in those retained for the crop. It is obviously a great mistake to allow superfluous shoots to make inches of growth before being removed from the Vines, or for that matter, from fruit trees of any description, especially Peaches and Nectarines, thereby wasting the forces of the trees, which should from the beginning be directed to the development of the necessary number of growths and leaves, and the building up of strong, healthy, fruitful Vines and trees.

Mr. Castle says that "undoubtedly practice combined with thought leads to success." I may be allowed to supplement this assertion by saying that the sound, thoughtful, and energetic practitioner who is given fairly good accommodation and the means wherewith to carry out his work is sure to succeed in producing results of the best description under ordinary good climatic conditions. The practice that leads to success must be sound, and be thoughtfully and energetically carried out.

Leaving laterals 1 foot apart on each side of rods of the Black Hamburg Vine, and each lateral having six leaves, as recommended and apparently practised by Mr. Castle, appears to me to be at the least 3 inches too close to allow of due leaf development. Mr. Castle's contention that "a large leaf is far more value than any amount of small foliage or elongated wild growths" is so far good, but I am not at all sure that his method of attaining the end in view is so satisfactory as it should be, seeing that it tends to a crowding of growth and foliage. Would not the individual leaves and the buds in the axils of same be larger and of better texture, and more thoroughly ripened, were the sub-laterals pushing from the base of the said leaves along the main laterals pinched clean out of all Vines as soon as they appear, the same as Mr. Castle serves his Muscats?

In the case of young Vines intended for fruiting the year after they are raised from eyes and planted out, I always pinch the laterals as soon as they appear, stopping the individual Vines when about 3 feet high, pinching out the lateral growth resulting from this stopping in the axil of the top leaf later on. This, after an interval of about ten days, will cause the bud in the axil of the leaf, and which would otherwise have remained dormant until the following year, to push into growth. Meanwhile, the check thus given to top growth, the flow of sap is directed to thickening of the Vine below, and the plumping of the eyes or buds located in the axils of the leaves, as well as the enlargement of the latter, the operation being repeated after a fresh growth of 2 feet in length is made, and so on until the desired length of rod is attained. Thus treated a uniform thickness of rod and plumpness of buds are secured, and speaking from experience of this and other methods of procedure I give a decided preference to the system described above for permanent as well as supernumerary Vines. Our aim should always be to avoid as much as possible wasting the forces of Vines, or fruit trees in general, by allowing them to produce and mature wood which we know very well must be removed with the pruning knife at the fall of the leaf—that is allowing a Vine or tree to produce and ripen more wood and foliage than is absolutely necessary for the permanent welfare of the same.

It is generally assumed that the restriction of top growth favours the production of fibrous roots—that is, that the slight check given to top growth by stopping and pinching of the shoots is communicated to the roots, and that following this slight check fresh and additional roots are emitted from the side of those whose growth had been slightly interrupted. But is this really so? Much good may be done by raising the question.—H. W. WARD.

ANYTHING in connection with Vines is always interesting to me, and I have read all that has been written on summer pruning or pinching Vines. In my first lesson on pinching Vines I was told to pinch the lateral when it made two leaves beyond the first bunch, and stop the sub-laterals at the first leaf; and as I was anxious to keep forward with my work, I stopped the laterals as soon as I could perceive the second leaf when in a very small state, but that was too soon for my

employer, as he wanted them to grow about 6 inches beyond the second leaf before being pinched back to it.

The above treatment I still consider sound for old or weakly Vines, but I would take most of the sub-laterals off when the Grapes begin colouring. With younger Vines I have found that by stopping them one leaf beyond the bunch, and doing so as soon as the leaf can be seen, and when it is only about the size of a shilling, that the bunches come larger than when they are allowed to extend much farther before doing so. I also pull off all sub-laterals excepting one at the point and two at the base as soon I can get hold of them. The one at the point is stopped at the first leaf when it can be done; the two at the base are allowed to make two or three leaves before being stopped to the first leaf. The idea of allowing these to grow more than the others before being stopped is that it strengthens the buds at the base, which is of greater importance, as it is from these buds the next season fruit comes from. But these sub-laterals at the base are removed entirely as soon as the fruit is ripe.

Although this close stopping is beneficial I would caution young gardeners and amateurs not to stop so closely, as there is a danger of forcing the buds that should lie dormant till the following year. During the time the Grapes are stoning I allow the sub-lateral at the point to extend, but it is stopped as soon as the second swelling commences, and they are allowed to grow again after the fruit is ripe.—J. L. B.

## ROYAL HORTICULTURAL SOCIETY.

APRIL 25TH.

THE Drill Hall on this occasion presented a gay appearance. Orchids were fairly well represented, as also were greenhouse and stove plants. Hardy plants, however, formed the bulk of the exhibits. Auriculas and Primulas were extensively staged, this being the annual exhibition of the National Auricula and Primula Society.

**FRUIT COMMITTEE.**—Present: P. Crowley, Esq. (in the chair), with Rev. W. Wilks, Messrs. H. J. Pearson, Peter Veitch, Harrison Weir, G. Taber, J. T. Saltmarsh, A. Dean, G. Sage, G. Wythes, J. Hudson, H. Balderson, F. Q. Lane, J. Willard, J. Smith, G. W. Cummins, A. Moss, and J. Wright.

Mr. J. Smith, gardener to W. R. Inglis, Esq., Reigate Hill, sent a scarlet-flesh Melon, Hamilton's Defiance, a variety of promisc, but not quite ripe, and the Committee requested to see it again. Six seedling Melons, the result of a cross between the Countess and Royal Ascot, were sent from the Royal Gardens, Windsor. Medium sized slightly netted fruits with a greenish white flesh, tender, sweet and juicy. A box of Strawberries, La Grosse Sucrée, very large well coloured fruits from the same gardens, merited the cultural commendation awarded.

Mr. C. E. Munday, gardener to W. A. Wykeham Musgrave, Esq., Thame Park, sent a dish of Strawberries, Walker's Early Prolific, for certificate. The fruits were much like President, and the Committee thought the variety should be tried at Chiswick. Mr. J. Miller, gardener to Lord Foley, Ruxley Lodge, Esher, sent fruits of the white Bicton Pine Strawberry, which were conspicuously mixed with Keen's Seedling and others (vote of thanks). Messrs. James Veitch & Sons exhibited dishes of Gunton Park, Lord Suffield, and Empress of India Strawberries, fine fruits of promising varieties which have been previously certificated (vote of thanks).

Mr. G. Wythes sent fruits of Amsden June Peach, from a tree planted in December, 1890. From this tree seven dozen fruits were gathered in May, 1892, and nine dozen in April, 1893, the first ripening April 12th. The award of merit granted to Mr. Wythes for this Peach in 1892, as an early variety, was confirmed. It is a clingstone Peach. Mr. Wythes also sent clean uniform tubers of Sharpe's Victor Potato, grown in nine weeks. An award of merit was granted for it as a forcing variety of proved usefulness. Mr. J. G. Dean, The Gardens, Titsey Place, Limpsfield, sent eighteen varieties of Apples, most of them firm, and a vote of thanks was unanimously accorded.

**FLORAL COMMITTEE.**—Present: Mr. G. Paul (in the chair), and Messrs. H. Correvon, H. Herbst, H. B. May, G. Stevens, G. Gordon, J. Jennings, C. E. Pearson, W. Furze, C. E. Shea, J. D. Pawle, P. Barr, T. Baines, C. Noble, J. Walker, J. Fraser, and W. Watson.

Roses formed an interesting feature. Mr. W. Rumsey, Joynings Nursery, Waltham Cross, sent a group of Tea and Hybrid Perpetual varieties in pots. The flowers were fresh and exceedingly bright. Mr. Rumsey also had a box of Niphetos blooms, and another of mixed Roses, amongst which Ethel Brownlow, Senateur Vaisse, Charles Lefebvre, and Marie Finger were particularly fresh (silver Flora medal). Messrs. W. Paul & Son, Waltham Cross, had a splendid collection of trained Roses, which included the strong growing Moss Zenobia, and many of the best Hybrid Perpetuals. Jennie Dickson, a Hybrid Tea, was also well shown in this collection (silver-gilt Flora medal). Messrs. G. Paul & Son, Cheshunt, sent pot Roses, and a number of hardy flowers in pots. Amongst the latter were Phlox canadensis, Iris pumila aurea, Anemone Robisonianum, and Adonis vernalis (silver Banksian medal). J. C. Tasker, Esq., Middleton Hall, Brentwood (gardener, Mr. Perry), also had some well grown Roses; and Mr. Walker, Thame, sent three boxes of Maréchal Niel, and a box of Zonal Pelargoniums (silver Banksian medal). The cut Roses sent by Mr. Frank Cant, Colchester, were remarkably fine, and attracted much attention (silver Banksian medal); and the three boxes of Maréchal Niels and a box of Pansy sprays sent by Mr. A. Smith, Prospect House, Downley, High Wycombe, were accorded a vote of thanks.

Messrs. P. Barr & Sons, Long Ditton, sent a representative collection of Narcissi and other hardy flowers (silver Banksian medal). Messrs. E. D. Shuttleworth & Co., Albert Nursery, Peckham Rye, sent hardy plants in pots and cut Narcissi blooms (bronze Banksian medal). Messrs. J. R. Pearson & Sons, Chilwell, also had an interesting group of Narcissi, amongst which the comparatively new Madame De Graaf was well represented (bronze Banksian medal). Mr. G. H. Cammell, Brookfield, Heathersage, Sheffield, won the first prize for a collection of Daffodils.

Calceolarias were shown in good condition by Messrs. J. James and Son, Farnham Royal, Slough, the flowers being large and well coloured (silver Banksian medal). Mr. T. Bullen, Hithergreen, Lewisham, sent a dwarf-growing Cape Calla, with a bright yellow spathe, for naming, also some with cream-coloured spathes. Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, had a collection of Primula Sieboldi in variety, the best being Ruby Queen, Magenta Queen, Ruby, Novelty, and Admiration (bronze Banksian medal). Messrs. J. Peck and Sons, Roupell Park Nurseries, S.E., sent a large collection of Gloxinias tastefully arranged with Adiantum cuneatum (bronze Banksian medal). Messrs. W. Cutbush & Sons, Highgate, were represented by Calla Little Gem, and various hardwooded plants (vote of thanks). Messrs. B. S. Williams & Sons had Abutilon Souvenir de Bonn, for which an award of merit was adjudged. This is described elsewhere. The same firm staged Calla aurata and a distinct Epiphyllum named E. truncatum Russellianum Gartneri, and a group of miscellaneous plants (silver Banksian medal). Messrs. J. Veitch & Sons had small plants of the new Strobilanthes Dyerianus. A first-class certificate was awarded for this novelty, which is described elsewhere. The Guildford Hardy Plant Nursery Co., sent four baskets of Alpine plants, which included many choice species (silver Banksian medal). Some hardy Primroses were staged by Mr. R. Dean, Ealing.

Mr. H. Knowles, Horsell Nursery, Woking, sent two boxes of Daphne cneorum majus, a dwarf growing sweet scented form (vote of thanks). Messrs. B. S. Williams, in addition to the above mentioned exhibits, staged a group of Palms, Amaryllises, and other plants (silver Banksian medal). Messrs. E. D. Shuttleworth & Co. also sent a collection of miscellaneous stove plants and Orchids, all tastefully arranged (silver Banksian medal). Dr. Walker exhibited some new flower supports made of wire. Messrs. H. Lane & Son, Berkhamstead, sent some charming varieties of hardy Azaleas, the best being A. Raphael de Smet and Hilda. Awards of merit were accorded these, and they are described elsewhere. C. E. Smith, Esq., Silvermere, Cobham, staged some well grown Deutzias, for which a vote of thanks was accorded, and J. C. Tasker, Esq., staged a collection of Cannas, for which a bronze medal was recommended.

**ORCHID COMMITTEE.**—Present: H. Veitch, Esq. (in the chair), and Messrs. James O'Brien, S. Courtauld, T. B. Heywood, F. Sander, J. Jacques, E. Hill, W. H. White, R. B. White, A. H. Smee, C. Pitcher, H. Ballantine, H. M. Pollett, and J. Douglas.

A few good collections of Orchids were staged. Messrs. F. Sander and Co., St. Albans, sent an interesting contribution, well arranged and containing some choice things. Amongst these Cypripedium Goweri, C. Robinsonianum, Oncidium Roraimensis, Pescatorea Klabochorum, Cattleya Skinneri alba, Odontoglossum Roeblingianum (award of merit), Lælia Digbyana, and Dendrobium macrophyllum were specially good (silver Banksian medal). Messrs. W. L. Lewis & Co., Southgate, also staged a collection of exceptional merit. This contribution contained a charming little Cypripedium named Rajah Brooke, the spike carrying three flowers. Maxillaria Harrisoniae, Odontoglossum citrosum roseum, Cattleya Skinneri, and Lælia purpurata were also noteworthy. W. W. Mann, Esq., Ravenswood, Bexley, sent a fine plant of Cynoches pentadactylon; and Thomas Statter, Esq., Stand Hall, Manchester (gardener, Mr. R. Johnson), staged Cypripedium Measuresianum aureum, a brownish yellow variety. A fine specimen of C. Boxalli superbum and a piece of Dendrobium nobile (Statter's var.) came from the same source.

Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, sent a small but attractive group, amongst which Cypripedium Schröderae, C. villosum aureum, Cattleya Mendeli, and C. Schröderae were particularly noteworthy. Some Masdevallias, described elsewhere, were adjudged first-class certificates (silver Flora medal). G. Wigley, Esq., Dukenfield, Cheshire (gardener, Mr. C. Harris), sent a number of specimens; and C. E. Goodhart, Esq., Beckenham (gardener, Mr. W. R. Padbury), staged Cypripedium Walli in good condition. A botanical certificate was awarded for Saccolabium cerinum, which came from the Royal Botanic Gardens, Glasnevin. J. G. Lutwyche, Esq., Oakfield, Beckenham (gardener, Mr. J. A. May), sent Cattleya speciosissima Coureri; and Mr. J. Fitt, The Gardens, Panshanger, staged Odontoglossum Fittianum (var. ?), Cypripedium Crossianum, and others.

Some grand varieties of Odontoglossum crispum came from De Barri Crawshaw, Esq., Rosefield, Sevenoaks (gardener, Mr. S. Cooke); and Messrs. Condor & Raphael, King's Langley, Herts, sent three plants of the pretty Cypripedium niveum and other things. Messrs. Hugh Low and Co., Clapton, staged an interesting group, and among these Stanhopca Amesiana (award of merit), Cypripedium bellatum, C. Masterianum, Odontoglossums, and Oncidiums of sorts were conspicuous. Messrs. J. Veitch & Sons sent Lælio-Cattleya Ascania (Lælia xanthina × Cattleya Trianae) and Lælia Latona (L. purpurata × L. cinnabarina), two exceedingly interesting hybrids. The first-named is described below. Mr. C. Winn, Selby Hill, Birmingham, had Dendrobium Nestor (D. Parishii × D. superbum); and Mr. W. Whiteley, Hillingdon, sent

*Odontoglossum excellens*, Whiteley variety. Messrs. B. S. Williams and Son had *Vanda teres* Andersoni, and *Diacrium bicornutum*, amongst other things.

#### CERTIFICATES AND AWARDS.

*Strobilanthes Dyerianus* (J. Veitch & Sons).—This is a beautiful foliaged plant, resembling some of *Bertolonias* so far as the colouring of leaves is concerned. The leaves are oblong, acuminate, and on the plants exhibited, which were small, were from 3 to 4 inches in length. The surface of the foliage is rosy lilac, relieved by prominent green veins. A valuable stove plant (first-class certificate).

*Lælio-Cattleya Ascania* (J. Veitch & Sons).—This is an interesting bigeneric hybrid, being the result of a cross between *Lælia xanthina* and *Cattleya Trianae*. The sepals and petals are pale yellow, the lip being a richer shade, with a rich purplish magenta tip (first-class certificate).

*Abutilon Souvenir de Bonn* (B. S. Williams & Son).—A pretty foliaged *Abutilon*, the leaves being of a rich green centre, with a white margin (award of merit).

*Azalea Hilda* (H. Lane & Son).—This is a most attractive variety. The flowers are borne in large trusses, and are of a bright orange shade (award of merit).

*Azalea Raphael de Smet* (H. Lane & Son).—A pretty semi-double variety with medium-sized blush flowers, suffused and edged with pink (award of merit).

*Stanhopea Amesiana* (Hugh Low & Co.).—This is a charming species with large sweet-scented flowers. The sepals and petals are cream, while the lip is white glazed like china, slightly spotted with brown in the centre (award of merit).

*Masdevallia Gelengiana* (Sir Trevor Lawrence).—A small growing interesting species. The flowers are pretty though not attractive, being of a dull cream shaded green, and covered with minute crimson dots (first-class certificate).

*Masdevallia Armini* (Sir Trevor Lawrence).—This a pretty dwarf growing species. The flowers are small, of a purplish magenta shade with a lemon throat, and greenish yellow tails (first-class certificate).

*Epidendrum macrochilum album* (Sir Trevor Lawrence).—The sepals and petals of this form are of a dull bronzy green shade, the lip being white with a magenta blotch. The specimen shown had seven spikes, with three to four flowers on each (award of merit).

*Odontoglossum Reeblingianum* (F. Sander & Co.).—An attractive species; the sepals and petals are cream, densely spotted with chocolate, as also is the lip; the throat is lemon yellow, and spotted brown (award of merit).

*Maxillaria Sanderiana*, var. *xanthoglossa* (F. Sander & Co.).—This is an exceedingly showy variety. The petals and sepals are white, densely spotted with crimson, deepening to a dull reddish shade in the centre of the flower. The tip of the lip is fimbriated, and a pale yellow shade (award of merit).

#### ALPINE FLOWERS.

The paper on these plants, written by Mons. H. Correvon for the afternoon meeting at the Drill Hall, was read by the Rev. W. Wilks, Sir John Llewelyn, Bart., occupying the chair.

The essayist treated the subject in an excellent and exhaustive manner. It was pointed out how almost all the plants growing on the side of the Alps at a high altitude were dwarf and stunted, forming dense carpets of leaves and a great number of flowers, which were practically stemless. This was the case even with plants which on the plains were grown as shrubs. The essayist said how much different were the true Alpine plants when growing in England and when in their native habitats. Often when seeing the plants in the rockery at Kew and in the garden of G. F. Wilson, Esq., at Weybridge, he had been astonished at the fine growth which they had made, and which demonstrated plainly how eminently suited was the climate of England to their requirements. But if we in England had the advantages in many ways they in Switzerland had them in others.

The propagation of the plants was, said the essayist, a matter of peculiar importance, as owing to so many visitors going to the mountains and some of them taking roots of the plants which were at the time of the visit in flower, many species and varieties were rapidly becoming extinct, whereas if they would but make use of seeds to procure a stock no such misfortune would happen. Though occasionally some of the seeds were a long while in germinating, it was an undoubted fact that plants raised in this manner flowered more profusely, were more robust in habit, and far harder than those obtained from cuttings or division of the roots. This, the essayist remarked, was an excellent reason why plants should be raised from seeds, which were in the majority of cases readily procurable. The three great essentials to health with Alpine plants were warmth, light and moisture, and these were to be had in Switzerland, the two former from the sun and the latter from the ground, coming from it in the form of a dense vapour, which while supplying moisture to the leaves, at the same time protected them from the otherwise too powerful rays of the sun. The flower buds of the plants were formed mainly in the autumn, and were thus ready to burst into bloom on the first disappearance of the snow during the following year. The adaptability of walls for the cultivation of great numbers of the Alpine plants was also most intelligently treated, and growers were advised to try them in this manner, even when they had failed to achieve success when giving the plants a rich soil in which to grow.

A few questions were asked by members of the audience (an unusually large one) to which Mons. Correvon answered in an

eminently satisfactory manner, making himself readily understood by his good English.

A hearty vote of thanks was accorded to Mons. Correvon for his admirable paper, to the Rev. W. Wilks for reading it, and to Sir John Llewelyn for presiding.

#### NATIONAL AURICULA AND PRIMULA SOCIETY.

APRIL 25TH.

THE annual Exhibition of this Society was held at the Drill Hall, James Street, S.W., on Tuesday, in connection with the meeting of the Royal Horticultural Society. Owing to the prolonged spell of drought and abnormal heat some difficulty had apparently been experienced in retarding the blooms, many of which had lost their freshness. Still the exhibits were fairly good although a little below the usual standard. Appended are the names of the prizewinners in the various classes.

The Rev. F. D. Horner, Burton-in-Lonsdale, Kirkby Lonsdale, was awarded the first prize for twelve Show Auriculas in distinct varieties. This exhibit was composed of Doris, Achilles, Charmer, Dusk, Alexander Meiklejohn, Magpie, Green Linnet, Shirley Hibberd, Monarch, George Lightbody, Heatherbell, and Chloë. The plants were excellently grown, the flowers being of fine form, and the trusses large and compact. Mr. T. E. Henwood, Hamilton Road, Reading, was accorded second prize for a very fine exhibit; and Mr. Douglas, gardener to Mrs. Whitbourn, Great Gearies, Ilford, third.

In the class for six distinct varieties the Rev. F. D. Horner was again first with fine examples of Grayling, Alexander Meiklejohn, Rev. F. D. Horner, Ladybird, Magpie, and Dusk. Mr. Henwood was second, whose exhibit, though good, did not have the substance of Mr. Horner's. Mr. Sanders was third, Mr. Douglas fourth, and Mr. Jas. Weston fifth. W. Smith, Esq., The Links, Bishops Stortford, was accorded the first prize for four distinct varieties, staging fine plants of Mrs. Dodwell, Rev. F. D. Horner, Mrs. A. Potts, and Geo. Lightbody. Mr. Leonard Brown, Brentford, was second; and Mr. Patterson, Ashburn, Sunderland, third. In the class for two distinct varieties Mr. Leonard Brown was first with Mrs. Dodwell and Rachel; W. Smith, Esq., being second with two charming plants; Mr. C. Phillips, Hamilton Road, Reading, third; and Mr. Patterson fourth.

For a single specimen plant, the Rev. F. D. Horner was first, staging his namesake, and third with Attraction; Mr. Henwood second with a good plant, and fifth; W. Smith, Esq., fourth; Mr. C. Phillips, sixth; Mr. Patterson, seventh and eighth. Rev. F. D. Horner was first in the class for a grey edged specimen, staging Geo. Lightbody; Mr. Henwood second with a fine plant of Lancashire Hero, and third; W. Smith, Esq., fourth; Mr. Patterson, fifth; Mr. Douglas, sixth and seventh. In the class for a single white edged specimen, the Rev. F. D. Horner was first and second with Magpie, the plants being very fine; Mr. Henwood was third and fourth with charming examples of Mrs. Dodwell; W. Smith, Esq., was fifth; Mr. Sanders, sixth; Mr. Patterson, seventh and eighth. In the class for a single specimen, self, W. Smith, Esq., was first and second with Black Bess; Mr. Henwood third and fifth with Mr. A. Potts; Rev. F. D. Horner, fourth; Mr. Douglas, sixth and seventh.

For fifty Auriculas of not less than twenty varieties, which could include Alpines, Mr. Chas. Turner, Royal Nurseries, Slough, was first with a grand exhibit, prominent in which were Winifred (Alpine), Rev. F. D. Horner (green edge), Dora (Alpine), Mr. H. E. Milner (Alpine), Mrs. A. Potts (self), Chas. Phillips (Alpine), and Patience (Alpine). Mr. Douglas was awarded the second prize with a very creditable exhibit. Mr. W. L. Walker, Reading, being third.

Mr. Chas. Turner was first in the class for twelve distinct Alpines, staging grand plants of Fred Knighton, Winifred, Roland, Mrs. Harry Turner, Dash, Countess, Patience, Hubert, Hotspur, and three very fine unnamed seedlings. Mr. Phillips was second with a very good group, Mr. Douglas third, Mr. W. L. Walker fourth, and Mr. Sanders fifth. Mr. Phillips was awarded the first prize for six Alpines, distinct varieties, showing Mrs. F. Barrett, Mrs. G. W. Palmer, Baroness Burdett Coutts, Mr. F. J. Blandy, Mrs. Martin, and Saturn all in good condition. Mr. Turner was second, Mr. Douglas third, Mr. Walker fourth, and Mr. Sanders fifth. Mr. Patterson was first for four distinct varieties of Alpines, staging Diadem, King of the Belgians, Mrs. Dodwell, and Phillip Frost. In the class for a single specimen Alpine Auricula with a gold centre was given to Mr. Chas. Turner with H. M. Pollett; Mr. Phillips was second and fourth; Mr. Douglas third; Mrs. Blackett Gill, The Stone House, Caterham, fifth. Mr. C. Turner was again first in the class for a single specimen plant with a white centre, showing Lady Laura Hampton, and was also second with Winifred; Mr. Sanders was third, Mr. Douglas being fourth and fifth.

For six gold laced Polyanthus, dissimilar, Mr. J. Weston was first with charming plants of George IV., Napoleon, John Bright, Lancashire Hero, Cheshire Favourite, and Lancer. Mr. R. Dean, Ranelagh Road, Ealing, was second. Mr. Sanders was first for three plants of gold laced Polyanthus in distinct varieties, showing William IV., John Bright, and Napoleon III. in good form. Mr. J. Weston was awarded the second prize. Mr. Patterson was accorded the first prize for a single specimen gold laced Polyanthus, showing a good plant of George IV.; Mr. Sanders being second, and Mr. Weston third and fourth.

In the class for twelve Fancy Auriculas Mr. Douglas was first with a charming exhibit, and Mr. Weston second. For twelve Fancy Polyanthus, in distinct varieties, Mr. Douglas was again first with magnificent plants, and Mr. R. Dean second. For twelve single Primroses, in

distinct varieties, Mr. Douglas was first with grand plants, and Mr. R. Dean second.

The Guildford Hardy Plant Nursery, Mill Mead, Guildford, was awarded the first prize in this class for twelve Primulas, showing amongst others *P. intermedia*, *P. rosea* var. *grandiflora*, *P. ciliata*, and *japonica alba* and *P. formosa*.

In the class for seedlings of the Show section Mr. Sanders was awarded the first prize for a grand variety named Engineer, a very dark self of rich velvety colour with a white paste. This variety will be an acquisition. In the class for Alpine seedlings with white centre, Mr. Chas. Turner was first with Winifred, Mr. Walker being second for an Alpine seedling with a gold centre. Mr. Turner was again first for a plant with a white centre, showing Fred Knighton.

The premier Auricula in the Show was a plant of Shirley Hibberd (green edge), exhibited by the Rev. F. D. Horner. It had a grand truss of eleven flowers.

Mr. Douglas was awarded the first prize for a charming group of Primulas and Auriculas, some very fine plants of each comprising the exhibit. Mr. R. Dean staged a number of hardy Primroses in pots, and Mr. Douglas two hampers of Primroses.

**THE WEATHER IN LONDON.**—The past week has again been characterised by bright sunny weather. During the day the heat has been abnormal, whilst the nights were quite warm. At the time of going to press there is no appearance of a change. Crops are greatly in need of rain.

— **WEATHER IN THE NORTH.**—The rain on the afternoon and evening of the 18th was followed by three exceptionally fine days, during which vegetation made great progress. A cold N.E. wind has generally prevailed for the last three days, causing the evenings to be chilly, although the days have been bright and fine throughout.—B. D., *S. Perthshire*.

— **EARLY ROSES.**—Mr. G. Fulford, The Gardens, Trafalgar, Salisbury, sends us Roses gathered in the open air—namely, *Maréchal Niel*, *Lady M. Fitzwilliam*, *Alba Rosea*, *Niphetos*, *Catherine Mermet*, and *Madame Willermoz*. They are very good.

— **ROYAL NATIONAL TULIP SOCIETY.**—We are informed that the next Exhibition of the Royal National Tulip Society will be held at the Botanical Gardens, Manchester, on May 23rd. Entries may be made up to May 15th.

— **THE ROYAL GARDENERS' ORPHAN FUND.**—The annual dinner of the supporters of the Royal Gardeners' Orphan Fund was held last night (Wednesday) at St. James' Hall, Regent Street, W. Baron Ferdinand de Rothschild, M.P., occupied the chair, and he was supported by a large and influential company. The chief speakers besides the Chairman were Sir John Llewelyn, Bart., Sir Trevor Lawrence, Bart., N. N. Sherwood and Arnold-Forster, Esqs. As these pages were passing through the Press at the time the dinner was taking place a full report must be deferred till our next issue.

— **PEAR PROSPECTS.**—We hear from various sources that though Apple blossom is setting well, that of Pears is leaving little or no fruit behind it. The flowers expanded freely, but sharp frosts occurring at the time destroyed the essential organs, and as a consequence there will be many fruitless trees, from which good crops of Pears were expected. At the same time we hear of full sets of Pears on wall trees, protected by glass coping or other form of shelter. We hope, however, that the failure of the Pear crop will not be general on unprotected trees. Perhaps correspondents will favour with observations on the subject of the promise of fruit.

— **MISS ORMEROD'S FIRST HOME.**—A slight error occurred in the citation on page 311 last week. The birthplace of this lady was not Chepstow Park, Sudbury, but Sedbury Park, Chepstow. Her father's property extended about a mile along the Wye and a mile along the Severn, the land between forming an unique hunting ground for the ardent naturalist.

— **CUMBERLAND MAGISTRACY.**—We observe in the list of new County Magistrates for Cumberland the name of Mr. James Watt (Little and Ballantine), nurseryman, Carlisle, who has for several years been a Justice of the Peace for the city of Carlisle.

— **MR. DODWELL** writes from Stanley Road, Oxford :—"Will you kindly allow me in your column for personalia, on behalf of my wife and myself, to return our most grateful thanks to our many friends for their congratulations and gracious sympathy on the occasion of our golden wedding? Very devoutly we thank them and thank God for this pleasant sunlight of our evening days, and we hope we shall be permitted to have the joy of personally tendering our thanks to a large company on August 1st (will they kindly note the date?) the day appointed for our annual Carnation feast."

— **A FINE ADIANTUM FARLEYENSE.**—A grand specimen of this Fern is at the present time growing in the garden of C. H. Gatty, Esq., the owner of Felbridge Place, East Grinstead. This plant, under the care of the gardener, Mr. Jupp, has developed during the past three years into one of the finest and healthiest to be found in England. It is fully 8 feet in diameter, faultless in colour and symmetry of form, the fronds overlapping each other in that graceful and enchanting style so well known in this variety. There are many noteworthy specimens at Felbridge Place, especially Conifers. I hope to see these fully described in the *Journal* shortly.—F. D.

— **CHRISTMAS ROSES AND LIQUID MANURE.**—Those who are not in the habit of drenching thoroughly several times during the growing season of these plants with liquid manure I would advise them to lose no time, but to try its effect on Hellebores. I make a practice of supplying a fair quantity to the roots, out of doors, at a time when the crops of new leaves are being made, but this year I have given more owing to the weather being especially hot and dry for the last month. The extra luxuriant growth as compared to former years is a sufficient proof that the treatment is correct, as I have found out the crop of blossoms is regulated very much by the amount of growth made.—E. M.

— **LILIUM HARRISII.**—"W. S." observes :—"Some of the best plants of this popular Lily came under my notice recently that I ever remember witnessing in small pots before in the gardens at Heywood, Lord Justice Lopes' residence near Westbury, Wilts. At the time of my visit they stood about 5 feet in height, the stems exceedingly massive and the foliage large and healthy, although only occupying 7-inch pots. From seven to ten bloom buds were showing in the crown of each, which in flower will be very striking and useful conservatory plants. They are growing in a turfy mixture of soil, and obtain assistance from Thomson's Vine manure, which Mr. Robinson, the gardener, holds in very high favour as a plant food. That their cultural attention has been of the best is reflected in the condition of the plants in every detail, and not only does this apply to the plants under notice but in everything cultivated under glass."

— **STRAWBERRIES**, among other things, remarks the same correspondent, call for especial mention, and this will be more perfectly understood when it is said that the majority of the fruits of President—a favourite midseason sort at Heywood—weighs an ounce and upwards each. The fruits when set are reduced to nine on each pot, choosing of course those best placed and perfectly set. Sufficient plants are grown to maintain a constant supply from early in March till they are ready for gathering outdoors.

— **A NEW INDUSTRY IN PERTH.**—On Monday we had the opportunity of inspecting a new and quite a novel industry in the neighbourhood of Perth, already being conducted on a large scale, and which promises further development. It owes its origin to the enterprise of Mr. A. L. Rupe, Sunnybank, who, in November last, leased the market garden at Pitheavlis Orchard, Cherrybank. In addition to the ordinary market gardening business, he conceived the idea, owing to the large demand for Mushrooms, of cultivating this esculent fungus upon a large scale. Although Mr. Rupe only took possession in November last, he has already about 700 yards of Mushroom beds laid down, half of which is now in full bearing. For a short time early on Monday morning we watched the operation of picking, and were astonished to find that 1½ cwt. was speedily ready to be packed for Manchester alone, in time to catch the midday train, the most of them being fine, fleshy specimens. Mr. Rupe is under contract to maintain a regular supply all the year round.—(*Perthshire Constitutional*.)

— **DESTROYING INSECTS AT TODDINGTON.**—Further experiments with the Stott appliances were conducted at Toddington on Saturday last, and we are informed they were in all respects satisfactory. A large number of fruit growers assembled on the occasion.

— **SPRING FLOWERS IN HYDE PARK.**—The spring bulbs in Hyde Park have been flowering magnificently, but many of them are now rather past their prime. This, at any rate, is the case on the eastern side of the Park. The Narcissi are gone, and so are the Hyacinths. Many of them, indeed, have been already cleared away to make room for summer bedding plants. "Not for ten years," says Mr. Browne, the Park Superintendent, "have our bulbs been so forward as they are this year. Ten years ago they were past their best by the 7th of April, but we have never had them so forward since."

— **THE YOUNG GARDENERS OF FALKIRK AND THEIR HALF-HOLIDAY.**—If the head gardener who does not appear in favour of a half-holiday for his assistant gardeners lives within the radius that is embraced by the Falkirk and District Association, he would see by the circular sent out by the Association that he would not be required to do the necessary work, as the circular suggested that one of the assistants be left on duty to attend to airing and watering, or any necessary work. I hope he will now do all in his power to assist in furthering the Improvement Association, as he thinks it is time one was formed in Falkirk, if he can see his way to do so. Since my last letter another of the leading proprietors in the district has granted the half-holiday, and I hope it will not be long before all assistant gardeners will enjoy the same benefit.—A. G.

— **SATURDAY HALF-HOLIDAY.**—As gardeners have to keep up with the times in their work, it is not surprising they should also want to do likewise as regards holidays. For several years our men have left off at four o'clock on Saturdays; but this is too early in the middle of summer for closing many of the houses. What do the young men intend to do with the houses when they leave off at dinner time?—shut them up or leave them open till Monday? As Saturday is the busiest day, if they are to have a holiday, why not have it in the middle of the week or once a fortnight? Then half of the men could go each week, or a whole season's growth may be destroyed by one of these half-holidays.—J. L. B.

— **WEATHER REPORTS.**—I have great pleasure in replying to Mr. Easter's questions on page 315, but am not certain that I understand them rightly, unless the word "grass" has by some means been substituted for grass. The thermometers here are hung in a Stevenson screen at 4 feet above the surface of the ground. They have been tested and certificated at Kew, and are periodically examined as to their correctness by an officer of the Meteorological Society, who visits the principal stations for the purpose. All the mean maximum and minimum observations sent by me to the Journal are taken from these two thermometers, also the mean temperature of the various months. The grass thermometer is placed in a position fully exposed to the sky near to the Stevenson screen. It rests on a piece of turf, and the word "grass" is always added to all observations recorded from this instrument.—W. H. DIVERS, *Ketton Hall Gardens, Stamford.*

— **AWARDS FOR ENGLISH EXHIBITS AT GHENT.**—At the Ghent Quinquennial Show last week Messrs. Foster & Pearson, Limited, were awarded first prize, a gold medal, for the "Beeston" greenhouse heated with the "Beeston" boiler, also a silver medal for a span-roof frame. The roof lights of the greenhouse slide up and down, and are secured by a very simple arrangement at intervals of 3 inches, so that they cannot be lifted by the wind. The side lights are fast, and side ventilation is here given by the registered iron ventilators placed under the sill, so that the air is warmed by passing over the pipes as it enters the house. One door is provided for each house unless otherwise ordered. The lights can be at once removed if necessary to expose the contents of the house. The iron rafters which span from sill to sill give the "Beeston" houses great strength, and there is no danger of sides or roof giving way after a few years' wear. Messrs. J. Veitch & Sons were awarded a silver-gilt medal for a splendid collection of their world-famed Amaryllises, and Messrs. F. Sander & Co. secured a gold medal for six new plants. Messrs. W. Cutbush & Sons, Highgate, as we mentioned last week, were represented by an extensive group of hardwood plants. The Veitch Memorial prize for the best hybrid plant in the Exhibition was awarded to M. Maréchal, Liège, for *Vriesia brachystachys major*, a form having an inflorescence of greater length than the type.

— **LIME JUICE.**—As indicating the demand for this wholesome product we are informed that the "Hilda" has just arrived in the Mersey from Montserrat, West Indies, with 50,000 gallons, being the first arrival of new season's juice. This vessel is now regularly engaged in bringing over Montserrat lime juice, which is consigned solely to Messrs. Evans, Sons & Co., Liverpool.

— **GARDENING APPOINTMENTS.**—Mr. William Poole, for the last three years foreman at Nestell Priory Gardens, Wakefield, has been appointed head gardener to General Marsack, Elstead Lodge, Godalming. Mr. Frederiek Tapper, foreman at The Gardens, Rangemore, Burton-on-Trent, has been appointed gardener to Lady Scott, Sundridge Park, near Bromley, Kent.

— **WINCHESTER AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.**—The Committee of above Association have arranged for a practical test of the value of the so-called preventives of the Potato disease to be held the present season, the application of the remedies to be given before such of the members as care to be present. This is a very good idea, and worthy of consideration by other societies in other districts.

— **OUTDOOR AURICULAS.**—As evidence of the diverse nature and earliness of the season as compared with the average of preceding springs, I may mention that outdoors it was a most unusual thing to have Alpine or laced Auriculas in bloom at Bedford, when I lived there, in the middle of April. When I looked in at the seed growers last week I found hundreds of plants not merely in full bloom, but some were apparently getting rather past their best. Under ordinary conditions, even in cool houses and frames, it seldom happened that plants were at their best by the Auricula Show.—A. D.

— **HORTICULTURE IN SURREY.**—Mr. A. Dean, who with Mr. Luckhurst and Mr. W. P. Wright, has been assisting Mr. J. Wright in delivering lectures on horticulture in Surrey under the auspices of the County Council Technical Education Committee, gave the last of the winter course at Leatherhead on Tuesday last week, taking for his theme, by special desire, "Hardy Perennials," dealing with this popular section of garden flowers, from Christmas Roses to Michaelmas Daisies. The lecture was admirably illustrated by a beautiful show of hardy flowers kindly furnished by Messrs. Barr & Son from their Long Ditton grounds, also many bunches of charming varieties brought by Mr. Peters, (gardener to H. P. Sturgis, Esq.) and Mr. Mease (gardener to A. Tate, Esq.), Leatherhead. It need hardly be said that, whilst greatly assisting the lecture, these flowers were also keenly inspected at the close by the audience, whilst practical topics, such as vegetables, divided into respective sections and dealt with fully, and fruits in the same way, have proved exceedingly interesting. Flowers have hosts of admirers, and any talk concerning them is always followed with the liveliest satisfaction.

— **FIBROUS ROOTS.**—We find a surprising want of knowledge as to what is a fibrous root. Really a fibre, as technically understood, is not a root any more than a leaf is a branch of a tree. Roots, to be sure, are formed out of fibres, and when a tree has a number of small roots it is not uncommon to say that it has an abundance of fibres. Fibres are the small white, thread-like that are principally engaged during the growing season in gathering and collecting food for the plants, just as leaves do the same work for the branches. Towards the end of the year nearly all these fibres die; only a very few that are present live over until the next season. They are not roots. If, however, one lives over, it eventually becomes a root. Fibres, as thus limited, are of no sort of benefit to a tree in transplanting. What is needed is an abundance of healthy, vigorous, one or two-year-old roots. Sometimes people say that in order to transplant a tree successfully it is well to dig around it one year, first cutting off the main roots, and in this way getting a number of "fibres" for the next year. It is in this sense that the word tends to mislead. Fibres are not thrown out when these larger roots are cut but small roots. One cannot have too many of these small one or two-year-old roots in transplanting. They are full of life and vigour, and aid materially in supporting a plant. But fibres, as limited in their definition in this paragraph, are of absolutely no consequence, and in many respects are rather an injury than a benefit. We have known evergreen trees moved with what were supposed magnificent roots—that is to say, there were thousands of real annual fibres—and yet die afterwards, no one seeming to understand why it should be so; but the trouble is that this large mass of sponge-like threads prevents the earth from coming into contact with the large roots, and then they are far more of an injury than a benefit.—(*Meehan's Monthly.*)

— OPENING OF A PUBLIC PARK AT COLDSTREAM.—Wednesday last witnessed the opening of the Home Park for the use of the inhabitants of Coldstream. The park is the gift of the Right Hon. the Earl of Home of The Hirsell, and in order to show the appreciation of the general public for the generous gift, and of the great boon which it is expected to confer upon the inhabitants, a general holiday was observed.

— CARNATIONS IN AMERICA.—The popularity of the Carnation in America may be judged by the fact that according to Mr. Richard T. Lombard of Wayland, Massachusetts, in a paper recently read before the Horticultural Society of that State, nearly 4000 florists are engaged wholly or in part in growing Carnations for cut flowers. It is estimated that fully 200,000,000 of these flowers were sold last year, yielding above 1,000,000 dols. to the growers.

— LABELLING OF FOREIGN FRUIT.—The Government, says a daily contemporary, have decided to appoint a select Committee to inquire into the extent to which foreign fruit is sold as English grown. A large quantity of inferior fruit from abroad is sent to this country, where it is labelled "English grown." The Merchandise Marks Act might well be extended in this case, as it has become the custom to export English made packages to the continent to be filled with Tomatoes, early Potatoes, and fruit.

— HASTENING CABBAGES.—I presume "A. D." (page 316) alludes to the market supply when referring to the stationary manner of the autumn planted Cabbages, as in private gardens there is no occasion to allow them to remain long in this state. In the case of the plantation of any one variety a portion ought to be hastened on by giving them a thorough soaking of liquid manure if dry weather is experienced during the latter half of March. In the absence of liquid manure a sprinkling of nitrate of soda on the soil about the roots, washing it in with clear water, answers the same purpose as the liquid manure. In addition to hastening for use a portion of the stock it prevents a glut at one time, this being the only fault of Ellam's Early that I have experienced—viz., the whole crop "turning in" simultaneously.—E. M.

— WEATHER AT SWANMORE.—Another week has passed since my last note, and still no rain has fallen. With the exception of the slight shower recorded of 0.04 inch on the 16th, fifty-two dry days have been experienced. The sun has increased in power; to-day (24th) the thermometer registered 84° in the shade, with a minimum temperature this morning of 44°. On the 20th, 84° were also registered, the minimum being 52°. On Friday the readings were 82° shade maximum, 54° minimum; on Saturday, 79°, 54°; and on Sunday, 80°, 42°. What a contrast in the temperature as compared with the last two years at the same date! On April 20th, 1891, the readings were 56° and 32°; on the 24th of same month and year the register was 68° and 31°. On the same dates in 1892, 51° and 31°, 68° and 42° were the figures recorded. Thermometer in shade to-day (25th inst.) registered 87°, minimum 49°. In 1891, 57° and 31° was the reading; 1892, 61° and 39°. The grass on the lawns here is now quite burnt, in many places equally as bad as in the Jubilee year. The temperatures have been registered by a corrected thermometer.—E. MOLYNEUX.

— WINTER TOMATOES.—I saw the sample of Tomato "Lady Bird," placed before the Fruit Committee of the Royal Horticultural Society, at the Drill Hall, on the 14th ult. Somewhen last autumn this variety, it will no doubt be remembered, obtained a certificate of merit as a winter-fruited variety. It was a most astounding award, because when on one or two occasions during the previous winter samples were shown, they were so very poor as to be unworthy of notice. Now, again, when fruits of the variety are sent, small deeply corrugated, like many of the old or outdoor sorts, and in the month of March also, they are found to be so poor as to merit no notice—indeed, those I saw would not have sold, even at the present time, retail at more than 3d. per pound, so inferior were they to the best imported fruits, and yet this is a variety that has been awarded a first-class certificate because of its winter fruiting merits. Can such an award be justified? If this be the best winter-fruited Tomato we have, then bad must be the worst. The variety has no special merit as a summer fruiter beyond many others. If anyone can give us a variety of Tomato that will not only set and fruit freely in winter, but also give good handsome fruits four to the pound, they will render the home grower much service.—A LOOKER-ON.

— A WORLD'S HORTICULTURAL CONGRESS will be held in Chicago in August, and, says the "Garden and Forest," papers are to be read on the following subjects:—Technical Horticultural Education, Relation of Experiment Stations to Commercial Horticulture, Horticulture in its General Relation to Art, Improvement of Public Grounds (schoolyards, cemeteries, highways, the development and preservation of natural beauty).

— PAID SECRETARIES OF HORTICULTURAL SOCIETIES.—*Apròpos* of your remarks on page 318 anent paid Secretaries, it may be interesting to state that by mere chance I was recently glancing through the annual report of the "West of Scotland Rosarians' Society," and came across the following item in the balance-sheet:—"Salaries of Secretaries and Treasurers, £7 7s." Here we have an instance of at least two gentlemen (I do not know how many more) sharing 7 guineas as salaries, whereas the Secretary of the National Chrysanthemum Society objects to about £50 per annum being termed a salary.—ONE INTERESTED.

— AGAPETES BUXIFOLIA.—Although easily grown and of handsome appearance, this plant has not hitherto received the recognition it deserves. It has been in cultivation for about forty years, but is still rarely met with outside botanical establishments. It is closely related to *Vaccinium*, but is superior to any of the *Vacciniums* usually grown under glass. It is of shrubby habit, and the long, slender branches are covered with small, dark green, Box-like leaves. The flowers are produced singly in the axils of the leaves on the ripened wood. They are tubular, fully an inch in length, and of a bright red colour. The plant is naturally an epiphyte, and in its native habitat (Bhotan) is found growing on the trunks of trees. It succeeds admirably, however, either planted out in beds or in pots in sandy peat. It will thrive in any ordinary greenhouse. Although it attains a height of 4 or 5 feet, small plants flower freely, and are very attractive. Propagation is readily effected by inserting cuttings of half-ripened shoots in fine peat and sand in a mild bottom heat.—A. B.

— FLOWERS IN MASSES.—Looking at a mass of *Alyssum saxatile*, *Iberis gibraltarica*, and *Phlox setacea* on the rockery here to-day I thought how much more effective are such plants when growing in masses of, say, 4 feet square, as compared with the higgledy-piggledy method of arrangement—a plant here and there by itself. Not only does this method of planting apply to rockery plants, but to trees and shrubs, as well as to many things in the herbaceous border. *Gladiolus brenchleyensis* is more effective when growing in clumps of five or even three, as compared with single plants. The *Narcissi*, again, are much grander planted in clumps, as for example, *Horsefieldi*, *Sir Watkin*, or even the *Pheasant's Eye* variety. In a like manner note the effect of half a dozen plants of the Spanish Broom, *Gorse*, a clump of *Spiræa ariæfolia*, *S. prunifolia* fl.-pl., or even a mass of *Dogwood* in the winter, in comparison with single bushes. Perhaps on the rockery the massing system of planting is the more effective as compared with isolated roots. *Gentiana acaulis* or *verna* are distinct proofs of this argument. *Aubrietias* afford excellent instances of the benefit derived in following the massing system.—E. M., *Swanmore Park*.

— LATE QUEEN BROCCOLI.—Mr. W. Strugnell, Rood Ashton Gardens, writes:—"I can fully endorse the remarks of Mr. Dunkin (page 296) as to the value and hardiness of the Late Queen Broccoli, and in many gardens I fear this is the only one remaining to any extent for furnishing a supply this spring. Even this has suffered in our case much more considerably than is usual for the variety; but the weather at the end of the last and commencement of the present year was of so severe a nature that without any protection from snow the results are not surprising. Broccoli is so valuable a crop that it can scarcely be ventured on to dispense with even midseason varieties, but as intimated by Mr. Dunkin it is a question for serious thought whether it is wise or not to occupy so much space with them. The dry weather experienced up to the time of writing (April 18th) has proved a great hindrance to the germination of the earlier sown seeds of Broccoli and other winter vegetables, and if it continues artificial watering must be resorted to, to obtain any plants at all from outdoor sowings. Assistance have been provided in the case of the midseason sowings by soaking the drills previous to depositing the seeds; but this will have to be further supplemented by watering if rain does not come soon. Next to Late Queen Veitch's Model has proved the hardiest with us, and these, though small, will be valuable as a change to forced vegetables and the long continued supply of winter greens, which are fast reaching the end of their tether."

— WINDSOR, ETON, AND DISTRICT ROSE AND HORTICULTURAL SOCIETY. — Mr. C. Romaine, Hon. Sec., The Priory, Old Windsor, writes :—"The 28th June having been fixed for the Rose Show at the Earl's Court Exhibition, the Show of the above Society is postponed to the following day, Thursday, June 29th. Intending exhibitors are requested to alter the date on their schedules and entrance forms."

— WEATHER IN NORTHUMBERLAND.—A daily contemporary recently observed, "The thermometrical readings taken on April 14th at Messrs. W. Fell & Co.'s Wentworth Nurseries, Hexham, showed the highest register to be 68°, and the lowest reading 24°, or 8° of frost. On the night of the 11th, or morning of the 12th, 10° of frost were registered, and within a few miles from Hexham there was ice an eighth of an inch in thickness on some standing water. The Plum and Pear trees are profusely covered with blossom, and the gardens now present a pleasing aspect. There is, however, a great need of rain."

— RHODODENDRON GRANDE. — This magnificent Himalayan Rhododendron was introduced in 1849 by Sir Joseph Hooker, who collected seeds and sent them to Kew. The specific name is very applicable, as good plants have a striking appearance both in flower and in leaf. The leaves are 12 to 16 inches long, and 3 or 4 inches broad. The large trusses are composed of about twenty of the campanulate flowers, each of which measures about 3 inches across. In the bud state they are rosy pink, changing with expansion to creamy white with a crimson stain at the base. It is figured in the "Botanical Magazine," t. 5054, as *R. argenteum*, a name under which it is no doubt familiar to many of our readers, and which has reference to the silvery under surface of the leaves. A rose-coloured variety originated at Kew some years ago, and is figured in the "Botanical Magazine," t. 6948, as *R. grande roseum*.—A.

— GARDENS IN TASMANIA.—If we may accept literally Sir Edward Braddon's glowing descriptions of gardens in Tasmania, says *Nature*, that island ought to be the paradise of horticulturists. Speaking the other day before the Indian section of the Society of Arts, he said of the garden he himself cultivated there for ten years: "All the year through that garden had its charms of colour and perfume to lavish upon me; always there were life and growth in progress, and new delights unfolding themselves out of Nature's bounteous lap." His monster Pelargoniums, that stood from 3 to 4½ feet high, and had a circumference of 9 to 27 feet, were sources of increasing pride and pleasure to him, as they were of successive glories of flower. As for his fruit trees and vegetable garden, they yielded a never-failing supply of food for the table that in England, purchased of the greengrocer, would have cost about £100 a year. "Many another garden like unto mine is there," said Sir Edward, "in Tasmania and New Zealand, gardens in which all the fruits and flowers of the temperate zone flourish abundantly, and in which it is possible for a European to work all the year round without fear of sunstroke or frostbite." These panegyrics were uttered in the course of an address in which the speaker tried to persuade Anglo-Indians that after their term of service in the East they would find it pleasanter and more profitable to settle somewhere in Australasia than to return to England.

— COMMODORE NUTT LETTUCE. — For forcing this is an extremely useful little Lettuce, growing quickly under moderate forcing, and being of medium size may be planted more closely in rows than Paris Market. From seeds sown on a mild hotbed in which were planted an early batch of Asparagus in February we had plenty ready for cutting by the last week of March. From that time several hundreds of Lettuces have been used, and a portion of the same sowing planted quite close to a south wall are now supplying firm, compact heads. These were put in quite as a chance crop, the early part of March not being a favourable time for planting Lettuces that have been raised under glass, and since these have done so well the regret is that more were not planted at the time. A mild bed prepared in time for transplanting the thinnings of the early sowing resulted in a matured crop quite as soon as those left undisturbed, though perhaps slightly less in size of head. I had not previously tried this early forcing variety, but its usefulness and quick maturity will ensure for it a permanent favour in our case for the purpose in question. Although I am not prepared to say that it is quicker in turning in than Paris Market generally, it was so with us, and its compact growth and trifling waste of outer leaves commends itself to the notice of those who require as many as possible from a small space. —W. STRUGNELL, *Road Ashton Gardens*.

— PHOSPHATES FROM INDIA. — Sir J. B. Lawes has recently received, through the India Office, a consignment of phosphates from Madras, with a view of their commercial value being ascertained. The specimens, of which we ("Natural Science") have been favoured with samples, are well formed nodules, with a nearly smooth buffish coat, and internally appear very pure. Unfortunately, they show no traces of fossils; but they come from Utatur, where there are both cretaceous and eocene beds.

— FLOWER SHOW AT VIENNA.—The Archduke Charles Louis opened the Flower Exhibition of the Horticultural Society of Vienna on April 19th. All the fine gardens in the neighbourhood of the capital contributed. Count Harrach's beautiful Azaleas were a prominent feature in the Exhibition. Herr Marx had two splendid groups of Roses, and the Horticultural Society a splendid group of miscellaneous plants and flowers. A magnificent group of Palms, shrubs, and flowers, covering an area 40 feet long and 30 feet broad, was staged. Pitcher-plants were also well represented.

— EARLY HAWTHORN BLOSSOM.—I send a piece of White Thorn nearly out in bloom picked in one of our lanes. Some is still more advanced. This is unusually early. Apple trees here are making a splendid show. The long and severe drought and heat are, however, retarding the growth of the herbage considerably, and in consequence cattle as a rule are suffering a great deal and looking very poor. In many places the soil is quite "gaping" owing to the heat.—ALBERT ROOD. [Our correspondent neither gives date nor locality in his letter, but the post-mark on the envelope appears to be "Bridport."]

— CHOISYA TERNATA.—"E. M." writes :—"Those who have not grown this pretty Mexican shrub at the foot of a south wall have missed a treat. At the present time we have two plants of it growing in such a position completely smothered with its pure white blossoms. The plants in question cover a space 15 feet wide and 5 feet high. The method of training the branches should not be a close one, but allow them to grow freely outward, resulting in more bloom. This Choisya is one of the easiest plants to propagate imaginable, stubby side shoots 3 inches long inserted in sandy soil around the edge of a 3-inch pot, plunged in a gentle bottom heat strike readily."

— EARLY FLOWERING OF PLANTS.—We ("Natural Science") would like to suggest the advisability of a more scientific method in the observation of dates of flowering of plants. One constantly comes across notes recording the exceptionally early appearance of certain flowers. It is forgotten, however, that the premature opening of the flowers may often mean death to the plant, or at any rate a serious waste of material. The production of seed is the final end to which all parts of the plant are modified. If by early flowering the plant is enabled to seed more freely, the date of flowering will tend to become earlier and earlier; but if the flowering is premature, and is not followed by the formation of seed, then the date will become later and later, as the too hasty individuals are killed off. Observers should not pick these early flowers, they should mark the specimens and return later on to see whether they have, or have not, produced any seed. No one appears yet to have noted whether the Buttercups and Dead Nettles, which flower more or less all through the winter, produce seed from the winter flowers.

— PRUNING AND TRANSPLANTING.—There is a difference of opinion, says "Meehan's Monthly," among some planters as to the propriety of pruning in the branches of fruit trees when they are planted. There is no question among those who have had extensive experience, they all concur as to the wisdom of pruning in under most circumstances when trees have been transplanted. It is chiefly from the evaporation of their juices faster than the roots can draw in sap to supply the place of that waste that they die, and pruning in the branches prevents too great an evaporation, and that is the reason why the practice of pruning in is to be commended. When the trees have been planted without such pruning, in the Pear, for instance, it is not unusual for them to remain a whole season and send out only a few leaves, and without making any growth of branches; indeed sometimes Pear trees remain the whole season alive without making any leaves at all. They are just able to meet the demands of evaporation, leaving nothing for growth. Whenever a transplanted tree does not show signs of pushing out leaves when the proper time comes to make leaves, the pruning knife should at once be called in, and the branches pruned. Hundreds of transplanted trees which die might be saved by a judicious use of the pruning knife.

**RHODODENDRON FRAGRANTISSIMUM.**

AMONGST the many hybrid Rhododendrons that are now in cultivation the above variety occupies a foremost position so far as its beauty is concerned, but it does not appear to be so generally well known as it

and Sons in 1869, and we have seen it flowering in the Holloway Nurseries.

The spray depicted in the illustration (fig. 63) was obtained from a plant grown by Mr. Stevens, gardener to W. B. Smith, Esq., Hetheret, Leigham Road, Streatham. The plant alluded to was a fine specimen,

FIG. 63.—RHODODENDRON FRAGRANTISSIMUM.

should be. *Rhododendron fragrantissimum* has been in cultivation for at least a quarter of a century, having been certificated by the Royal Horticultural Society in April, 1868. We are unable to trace its origin with accuracy, but it is supposed to be the result of a cross between *R. Edgworthi* and *R. ciliatum*. It was sent out by Messrs. Rollisson

and admirably illustrated the adaptability of this variety for greenhouse and conservatory decoration.

The flowers, as will be seen by referring to the engraving, are large, white, sometimes very faintly tinged with rose, and are deliciously fragrant.

#### THE WEST OF SCOTLAND ROSARIANS' SOCIETY.

THE Exhibition of the above Society will be held in the Victoria Hall, Helensburgh, on Friday, July 14th, and many of the classes are open to any growers in the United Kingdom. A good schedule has been prepared, the highest first prize offered being £3, or the Society's gold medal for sixty blooms, distinct varieties.

#### THE DEAN AND THE DUCHESS.

It is not long since one of our Scottish contributors, the Rev. David R. Williamson of Kirkmaiden, in a letter to his friend the young Duchess of Sutherland, recommended Her Grace to read the Dean of Rochester's book, assuring her that if she did so she would inevitably become, as hundreds have done after perusing the same volume, an ardent amateur rosarian. This prediction has been fulfilled, for since that period the Duchess has been assiduously engaged in establishing a Rose garden at her Lillieshall residence in Shropshire, with the assistance of Mr. Benjamin R. Cant, the Colchester rosarian.

We also understand that Her Grace has given Mr. Williamson an invitation to Trentham and Lillieshall, that he may have the pleasure of visiting her Orchid house at the former, and her miniature rosarium at the latter mansion house.

The Duchess of Sutherland, whose name is a valuable addition to the list of eminent amateur horticulturists, is a daughter of the late Earl of Rosslyn, and inherits her father's poetical gifts. She is the authoress of a picturesque book entitled, "How I Spent my Twentieth Year," which has already passed through several editions.

#### ROSES AND ROSARIANS.

I AM much obliged to "W. R. Raillem" for the information he has given me on page 310. As he appears to be well-meaning and equally well informed, I am quite willing to accept all his statements as correct.

The mistake regarding Madame Isaac Pereire was a trifling one, which I observed shortly after I had sent off for publication the article in which it occurred. If I rightly remember, "D., Deal," whom I greatly respect, spoke simply of that Rose as "Isaac Pereire." But this probably was done for the sake of condensation, and not from lack of knowing that the Bourbon variety in question represented Isaac's wife. It is, I find, included by Mr. Wm. Paul among Hybrid Perpetuals; but he speaks of it also as a Perpetual Bourbon, and I think that most rosarians, whether amateur or professional, will bow to his decision.

I may also say, while writing on this subject, that Mrs. Paul (I mean the Rose) is one of my most valued possessions. I have given her a commanding position in my garden, where she has the *Lilium auratum* (rubro-pictum) on the one side and the Duke of Edinburgh on the other, and I do not suppose she has ever received a better testimonial than I recently gave her in the *Journal of Horticulture*. So the great English, Scottish, and Irish rosarians are unanimous in pronouncing this magnificent Rose to be a pure Bourbon. I accept their verdict unquestioningly.

When recording in recent articles contributed to your Journal the great services rendered to amateur rosarians by the Dean of Rochester, one of whose latest disciples is the young Duchess of Sutherland, it was my intention also to have spoken appreciatively of those of the Rev. H. D'Ombraim, who has done much for the popularising of French Roses in England. His services to the more famous British raisers of this most beautiful of flowers have also been very great. This fact is acknowledged, as I am in a position to testify, by several of the most eminent English rosarians. For this and many other reasons I am sincerely glad to remember that a superb Bourbon Rose, well worthy of that honour, has been inseparably associated with his distinguished name. Happy are they whose efforts are thus crowned with a floral immortality!

—DAVID R. WILLIAMSON.

#### NOTES FROM IRELAND.

##### CARTON, MAYNOOTH.

THE princely and principal seat of the Duke of Leinster, situated in North Kildare on the borders of Meath, consists of a walled-in desmesne of 1000 acres, with four lodge entrances and an outer lodge at Maynooth giving entrance to a semi-private avenue leading to the desmesne proper. The world-famed college of St. Patrick faces the main street of Maynooth, whilst on the right are the massive ruins of its castle, with Ivy-clad keep some 80 feet high, bearing date 1180, a residence of the Earls of Kildare until Cromwell gained by treachery what his bombardment from Crew Hill failed to effect. Mementoes of the siege are to be seen at Carton in the iron cannon balls found about the old castle, together with a massive and curious stone table bearing a Latin inscription and date 1553, which, happily, has not suffered, and now stands in the centre of the Italian garden.

The mansion, built of dressed limestone, ranks with the finest of the

stately homes of Ireland, the southern front being very imposing, commanding a view of the Dublin mountains some twenty miles distant. The reception rooms, in keeping with the stately exterior, contain some fine ceilings, that of the salon, executed in the early part of last century, being a *chef d'œuvre* of Italian artists, whose names are commemorated on a brass plate. This room contains also a fine organ in a white and gold case, exquisitely designed by a member of the family. Generations who have passed away look down from the walls, and many heirlooms of the noble house of Fitzgerald are gathered here.

The desmesne is bisected by the Rye, a tributary of the Liffey, midway expanding into a lake of considerable dimensions, with several islands planted with Laburnums and scarlet Thorns. The Golden Elder is also conspicuous by the fine tone of colour it obtains in summer; while in winter very rich is the purple-red Dogwood fringing both islands and lake. Neither in England nor Ireland have I seen it so bright and effective as here. As with that, so with the golden and red Willows. The lake abounds with wild duck, and its smaller but more graceful cousin, the pochard, makes an annual visit from its Norwegian home. Herons and otters find here food to their liking.

At the south end of the lake is the cottage and grounds—outside a low, quaint, picturesque building; inside a bit of fairyland, walls and roof sparkling with shells and rock crystal, the work of a former Duchess of Leinster. The cottage is also a museum of Irish antiquities and curios from foreign lands collected by members of the family. The undulating grounds are pretty and interesting, containing some fine Coniferae, including good specimens of the feathery Hemlock Spruce. Near the cottage is the rare, sweet, white Fringe Tree, *Chionanthus virginicus*. West of the cottage Snowdrops grow *hiv et ubique*, and the river banks are clothed with at least an acre of *Omphalodes verna*, happy on the limestone, as is the double form of *Saxifraga granulata*. In a small enclosed garden for the use of the caretaker the old walls are cushioned with the modest *Erinus alpinus*, very beautiful in its deep purple glow, hidden from the outer world.

The river, after skirting the cottage grounds, flows partly through a natural rocky gorge. The Foetid Hellebore is abundant, and sheets of *Hypericum calycinum* drape the limestone; while the Spindle Wood (*Euonymus*) hangs out its coral decorations in early winter. Crossing the Black Bridges, on which grow the Ceterach and *Asplenium trichomanes*, the upper road is reached by the Queen's Pass, a steep carriage way, cut in the rock by Augustus Frederick, third Duke, and first used by Her Majesty, who visited Carton in 1849. Passing a fine plantation of Lilacs the Bogwoods are reached. Alterations (improvements perhaps) were made in the days of "Capability Brown" from designs furnished by him. If any vestiges of his work remain they are probably to be found here in some splendid Silver Firs, remains of avenues, which can still be traced. The green glades of the Bogwoods are lined with *Syringa* and *Rhododendrons*. Moygaddy, the northern part of the desmesne, is planted largely with Spruce and Silver Firs; here the finest *Rhododendrons* are found. That venerable horticulturist, the late Mr. Geo. Cunningham of Liverpool, told me he had many years since received a personal order from the Duke for some thousands; here they are, but he has passed away so quietly and unobtrusively, yet so strong a link connecting gardening past and present, that I may be pardoned this digression. When I first saw him on his annual Irish trip he said, "For forty consecutive years I have visited Carton, each time dining in the gardener's house." I need hardly say he continued to do so while I was there, nor how much I enjoyed the anecdotes of this gentleman, gardener, and scholar, who saw the death of Huskisson at the opening of the first railroad, and had dined with Paxton in the gardener's house at Chatsworth.

From the gardens facing the mansion a broad walk through a shrubbery leads to the kitchen garden. Midway on the right is a sequestered nook with some fine Tulip Trees, and large bushes of the Snowdrop Tree, *Halesia tetraptera*. Cedars in variety are plentiful; several trees of *C. Libani* are grand, but the Beech is par excellence the timber tree of Carton. Here in this shrubbery are giants sending far up their clean silvery grey boles, some with pendulous branches again sweeping down, the whole forming a beautiful avenue. In the autumn of that year of phenomenal sunsets early frosts had minted the foliage into old gold. One evening is indelibly impressed on my memory, when that weird after glow had relighted the dying day. The effect was magical. In stillness unbroken by the whisper of a leaf I feasted on this enchanting scene of Nature till night's curtain shut it out. Ere morning a gust of wind had brought the golden glory to the ground, where it lay, alas! nothing but leaves. "*Sic transit gloria mundi*."

The kitchen garden, 10 acres of which is enclosed by a lofty and substantial wall, was formerly more than double the size, being then continued to the boundary wall of the desmesne. Entering the garden the head gardener's house, old-fashioned, roomy, and comfortable, lays in a sunny nook. A long range of fruit houses bisect the garden transversely, behind these lay the plant houses and ranges of pits. Beautiful Yew hedges clipped into solid walls of green give good shelter. Pears do remarkably well on the walls, some very old but fine specimens of horizontal training tell of the long ago. As at Straffan on the Liffey, so here, spring frosts are troublesome. A long sheet of water bounding the garden on one side and continued into the shrubbery has been suspected, and probably is guilty of lowering the temperature, in which a few degrees either side of freezing point means so much with fruit trees in blossom.

Near the mansion is a small secluded plot of consecrated ground selected by the late Duke as his last resting place; and here, when a

united nation kept the Sovereign's Jubilee, was he laid, so soon to be followed by his bereaved lady the late Duchess of Leinster.

In closing these notes I may add they are more a character sketch of this fine old desmesne than an up-to-date account of it. Minor alterations have been made since the writer saw it, but the Duke inherits in a marked degree his ancestor's love of their noble trees. The Duchess is devoted to her Palms, Orchids, and hardy flowers, while Mr. Black, the head gardener, finds plenty to do in all departments, and does it well.—E. K.

## AIDS TO FRUIT CULTURE.

### GLASS COPINGS FOR FRUIT WALLS.

I WAS never before so much impressed with the great value and utility of this aid to outdoor fruit cultivation as I was a few days since on visiting the beautiful gardens at Hollowmead, Bishopsteignton, Devonshire, the residence of W. Barrow, Esq. The large kitchen garden is nearly in the form of a square, surrounded by good walls, one half of which—viz., those portions having a south and south-west aspect, having a light iron and glass coping about 20 inches in width of the pattern introduced years ago by Mr. Rendle.

Mr. Barrow had this coping erected some six or seven years since, and speaks in high praise of its value. Nearly the whole of the south wall is well covered with Peaches and Nectarines, the trees being in the very best condition and well furnished throughout with excellent wood thickly set with fruit, which is now being vigorously thinned. These, I am told, have never missed carrying heavy crops of fruit each season since the coping has been erected. Previously the trees scarcely ever ripened their wood fully and properly, carried their green foliage to very late in the season, and bore fruit very indifferently. Since the coping has been there, though, all this is altered. The wood ripens fully and early in the autumn, causing the leaves to mature and fall off early and large blossom buds to be developed. The fruit also is larger, more brightly coloured, and of better flavour.

On the south-west wall are Pears, Plums, and Cherries, all of which have set heavy crops of fruit, and are apparently deriving almost as much benefit from the glass above them as do the Peaches. Seeing, then, the great value of this aid to fruit culture, that its first expense is but very moderate, and the future cost in maintenance is very small indeed, one is led to wonder that it is not more frequently seen in fruit gardens. Certainly fruit cultivators have not all fully realised the changes it is capable of producing in their trees and their fruit crops, or it would be far more generally adopted.—W. K. WOODCOCK.

## THE SCOUNDREL SPARROW.

I AM disgusted to find that my best and finest Apple trees have been absolutely stripped of bloom—quite lately, since the green leaves have shown. This, I believe, to be the work of sparrows; I am always about, and must have heard or seen them if any bullfinches had come. The tiny blossom buds do not appear to have been eaten, but wantonly plucked off, and this looks like sparrows, which in some places treat Primroses and other flowers in this way. Besides polishing off all my Gooseberries and Red and White Currants, they have also destroyed my Black Currant buds, picking them all off when they were quite green.

I am close to a large farmyard, and where the sparrows swarm; the farmer complains bitterly of their depredations on his corn in July and August, but after the manner of his kind makes no attempt to stop their nesting by scores all over his premises.

But I have sworn vengeance, like the villain in the play, "No matter-r-r, a time will come!" I will have no mercy on the scoundrel sparrows, young or old, egg or nestling; in their time of weakness I will be their enemy. I too—oh, yes! I will feed them in the snow, like other benevolent persons; but the last item on their menu shall be dust shot. Boys shall be bribed to harry their nests. All the year round will I worry them. And if they injure my Apple trees next year I will forgive them!—W. R. RAILLEM.

P.S.—I have just seen three sparrows picking off the not quite opened blossoms of a Wellington Apple tree as fast as possible, and letting them fall to the ground. But the practice has become unhealthy among sparrows. All three died suddenly before my eyes.—W. R. R.

[Will all sparrow friends and sentimentalsists as readily "forgive" our correspondent?]

## AURICULAS AT SLOUGH.

A VISIT to the nurseries of Mr. Chas. Turner at Slough is at any time full of pleasure, interest, and instruction, and never more so than at this time of the year, when the Auriculas are in the zenith of their beauty. Knowing what such a visit had in store for me I availed myself of an opportunity, and in every way I was amply repaid.

To talk of Auriculas and their hybridisation to anyone genuinely interested in them is the delight of Mr. John Ball, truly a veteran and an authority on these flowers, as much so, in fact, as he is on Carnations. For a period of forty-five years he has been experimenting, and indeed vastly improving during the whole of that time. Many varieties, says this excellent authority, which were grown forty and fifty years ago and still prominently before the public, and may be found in all first-

rate collections. More especially is this the case with the show or stage section. Though the founder of the firm has passed away from our midst the records of his works are still with us, proving him to have been a florist in the truest and best sense of the word.

Amongst the best of the Show varieties in flower at the present time at the Royal Nurseries are:—Acme, a grand old white-edged variety which is still highly appreciated; Black Bess, a beautiful self of the most perfect-form; Trail's Beauty, a very fine white edge; Chas. E. Brown, a grey-edged of much merit; Conservative, a magnificent white-edged flower and possessing the somewhat unique distinction of having green foliage; Chas. J. Perry, a charming old self; George Lightbody, which amongst the green-edged still holds a place in the front rank; Heather Bell, a grey edge of much merit; Lancashire Hero, a grand green-edged; Heroine, a charming dark crimson self; Helen Lancaster, another self; Lord of Lorne, which ranks amongst the very best of the crimson selfs; Rev. F. D. Horner, a flower worthy the name, and the green edge of the day, perfect in every way; Mrs. A. Potts, a rich dark purple self, symmetrical in shape and strong in growth; Mrs. Dodwell, undoubtedly one of the finest of the white-edged; Richard Headly, a very fine grey-edged variety; William Brockbank, a fine bold flower with a perfect grey edge; Alexander Meiklejohn, also a grey edged, and many other very beautiful varieties.

Foremost among the Alpine section must be named Chas. Turner, which has a bright red ground shading to brown, with a pure golden paste, a beautiful flower indeed, and one which is worthy a place in every collection; Countess, dark ground shaded with lilac, and having a white paste, is a magnificent variety; Fred Knighton, black ground shaded red with a gold paste, is a grand flower. Harry Turner must be accorded a place in the front rank, for it is a truly charming variety with a white paste, the ground colour being almost black shaded with purplish red; the flower is of much substance, and of a shape which leaves nothing to be desired. Alarm is an early flowering sort, having a black ground with a reddish shading and a gold paste; Invincible has a gold paste, with a dark ground shaded deep red; Mabel is a very good variety, with a dark ground shaded plum and a straw paste; Mrs. Harry Turner has a white paste and a black ground, beautifully edged with violet, the flower is large and distinct, and the plant throws a very fine truss; Harry Furniss is a charming variety, black forming the ground colour, which is shaded and faintly edged with red, and having a clear gold paste; International is another very fine gold-pasted variety, the ground colour of which is black, clearly edged with bright red; John Ball is a rich dark crimson self with a bright yellow paste, the truss is of good size, and the flowers of perfect shape and substance; Winifred is one of the most charming varieties in the collection, the flower is perfect in form and substance, the ground colour being a very dark crimson beautifully shaded with lilac, and have a clear white paste; Mr. H. E. Milner has a straw paste and a rich crimson ground shaded with purple, and is a very fine flower; Mrs. Ball is a perfect flower, having a shaded crimson ground and a bright lemon-coloured paste; Magnet has a gold paste, the ground colour being rich crimson shaded deep rosy red; Roland is a very distinct variety, having a black ground shaded with rosy purple, the paste being yellow in colour; and Sunrise with bright gold paste, and black ground shaded rich crimson. There are many other highly commendable varieties, but these will suffice to show that the collection is an excellent and representative one, and comprises all the most meritorious kinds in cultivation.—VISITOR.

## NEWCASTLE SPRING SHOW.

APRIL 19TH AND 20TH.

THE spring Show of the Durham, Northumberland, and Newcastle-upon-Tyne Incorporated Botanical and Horticultural Society was held on Wednesday and Thursday, the 19th and 20th inst., in the Town Hall, Newcastle-upon-Tyne. The Society was fortunate this year in the weather, and the attendance both days was all that could be desired, and the receipts amounted to £70 more than last year, or a total of £193.

The Show was in every respect one of the very best the Society has ever held. The entries in many instances were numerous, and the hall was well filled with plants. The exhibits were of a very high class order, and to those that remember the inception of the first spring Show seventeen years ago the result is all the more gratifying. We may state that Mr. W. J. Taylor, who was formerly Hon. Secretary, who did so much in first raising the Show to the prominence it now holds in the horticultural world, is again a member of the Council. Appended is a list of the awards with notes of the exhibits.

In the A Division, which was open to all, for four plants, distinct, there were four competitors. Mr. Neil Black, gardener to Misses Pease, Southend, Darlington, was first and deservedly so. A fine Vanda suavis with eleven spikes and 105 expanded flowers was exceptionally subjected to keen inspection, and therefore warm admiration. This Orchid was a credit to the skill of Mr. Black. The other plants were a fine specimen of Rhododendrons Countess of Haddington and Veitchianum, and Erica Cavendishiana. Mr. J. Smith, gardener to T. Lange, Esq., Heathfield House, was second, with Rhododendron fragrantissimum and Imantophyllum miniatum. Mr. J. McIntyre, gardener to Mrs. G. Pease, Woodside, Darlington, was third, the best plants being Azalea Charles Eckbaute and Anthurium Andreanum. Azaleas were next, and were excellent examples of careful training, well flowered, and not too formal. Mr. J. McIntyre was first for four plants, showing Oswald de Kerchove, Marquis of Lorne, Duc de Nassau, and the white Daphne.

Mr. J. Smith was second with good plants, *Souvenir de Prince Albert* and *Duc de Nassau* being the best.

For the best three Orchids the competition was better than it has been at Newcastle before. Six exhibits were staged. Mr. J. Wood, gardener to E. Hopper, Esq., Morpeth, was first with *Dendrobium densiflorum* (eight spikes), and *Dendrobium Dalhousianum* (ten spikes), and *Cymbidium Lowianum* with thirty flowers. Mr. Thos. Wheeler, gardener to C. Mitchell, Esq., Jesmond Towers, was second with *Dendrobium nobile* 2 feet across and *Dendrobium thyrsiflorum*, and *Cymbidium eburneum picta*, the latter a well grown plant, the foliage faultless, and bearing eleven flowers; the back of the petal was slightly flaked with rose. This plant was very much admired by Orchid connoisseurs. Mr. J. Smith was first with Palms, *Kentia Fosteriana*. *Dielytra spectabilis* was fresh and highly coloured. *Deutzias* were also fine. Mr. J. Punton, gardener to T. Hodgkin, Esq., Benwell Dene, was first. In *Genistas* Mr. T. Park, 29, North Terrace, Newcastle, was first; and Mr. J. Charlton, gardener to N. A. Ritson, Esq., Jesmond Gardens, was first for six *Spiræas*. *Cinerarias* were superb, the flowers large, well shaped, and defined in colour. Mr. G. McDougall, gardener to Howard Pease, Esq., Arcot Hall, Dudley, was awarded the first prize, Mr. T. Wheeler was first with *Cyclamens*; and Mr. W. R. Armstrong, nurseryman, Newcastle, first for *Lily of the Valley*, and also first for six fine plants of *Keen's Seedling Strawberry*.

The table plants were keenly competed for, Mr. J. McIntyre being placed with plan's an equal height and thickness. *Croton Tortilla*, *Aralia Veitchi*, *Cocos Weddelliana*, *Dracæna superba*, and *Pandanus Veitchi*, and all draped with *Panicum variegatum*; Mr. J. Morris second; and the third prize collection, shown by Mr. T. Wheeler, contained the new *Dracæna Mrs. Laird* in good colour.

*Auriculas* have in recent years formed an important feature of this Exhibition, and there are now many growers in the north devoting their leisure hours to the cultivation of this interesting spring flower. For twelve *Auriculas* not less than nine varieties, *Alpines* excluded, Mr. R. Patterson, gardener to Mrs. Backhouse, Ashburne, Sunderland, was first, as has been the case since he commenced to exhibit at this Exhibition. Mr. Dodwell eight pips, *Black Bess* seven pips, *Heatherbell*, *George Lightbody*, *Acme*, and *George Rudd* were amongst the best of his flowers. Mr. T. E. Hay, Killingworth, was second; *Trail's Beauty*, *Acme*, *George Lightbody* were the best flowers of this old *Auricula* exhibitor. For six *Auriculas* and four Mr. T. Patterson was also first, and likewise for one green edged, one grey edged, white edged and self, he secured the same position. The *Alpines* were very good, the *Fancy* ones a fortnight earlier would have even been better, as the hot, strong sun has told upon them for colour. For twelve *Alpine Auriculas*, Mr. G. Lee, gardener to H. B. Watson, Esq., Millfield House, Newcastle, was first.

For one *Alpine Auricula* Mr. J. E. Hay was first, and for one *Auricula* seedling, equal to those in commerce, Messrs. J. Thompson and Son, Newcastle, were first. Gold laced *Polyanthuses* were well shown, Mr. J. Ellison being first with *Buck's William IV.*, *Formosa*, *Favourite*. Mr. R. Willis, Albion Row, Shankhouse, was second; and Mr. J. Cawthorne third. For a gold laced *Polyanthus* and for a seedling equal to those in commerce Mr. J. Ellison was also first.

With twenty-four *Hyacinths* there were five competitors. Mr. W. J. Watson, nurseryman, Fenham, Newcastle, was first. Owing to the season the *Hyacinths* were not so good as on former occasions, although creditable examples of skill were staged. For twelve *Hyacinths*, J. Hood & Co., florists, West Parade, Newcastle, were first, showing good blooms. Mr. W. J. Watson was second. Mr. G. McDougall was first for nine pots of single *Tulips*, and also first for six pots of double *Tulips*. For six pots of *Polyanthus Narcissus* Mr. W. J. Watson was first, and Mr. T. Wheeler second. For six pots of *Daffodils* Mr. T. Wheeler was first.

For cut *Camellias* Mr. Wm. Blackwood was first. For twelve *Rhododendron* bunches Mr. J. Wood, Morpeth, was first; Mr. Blackwood also scoring for *Azaleas*. *Roses* made a splendid show, *Maréchal Niel*, shown by Mr. A. J. Badenoch, Ponteland, securing the first prize.

*Pansies* were also an interesting exhibition, considering the season. Seven collections of Show *Pansies* were staged, and eight of *Fancy*, Messrs. T. Oliphant and J. Gardner being the respective winners.

*Drawing-room epergnes* were, as usual, numerous, and strongly competed for. Five were staged, all possessing commendable merit. Mr. G. Webster, Sunderland, was first; the arrangement was very perfect, the upper tiers were light and the base not too large. Mr. T. Pattison was second with an epergne where *Cattleyas* played the important part. Messrs. Perkins & Sons, Coventry, were first for bridal bouquets, and also for a hand bouquet containing the usual flowers. No less than fifteen ladies' sprays were staged, Mr. J. McDougall winning with an arrangement of dark *Roses*, probably *Sultan of Zanzibar*, and *Adiantum gracillimum*. Mr. Dougall is a new exhibitor and a young man, and his exhibit in every respect did him credit. The second prize exhibit, by Mr. F. Edmondson, was very good, and contained *Odontoglossum grande* and other choice Orchids. No less than twenty-five buttonholes were staged. Mr. T. Pattison was first with *Odontoglossum grande* and *Euphorbia splendens*, all neatly backed up with *Adiantum gracillimum*.

The B Division was open to all, nurserymen excepted. Messrs. J. McIntyre, J. Smith, Geo. Corbett, J. Punton had winning *Azaleas*, *Acacias*, *Dielytra spectabilis*, *Deutzia*, and *Spiræas* in the order named. For six *Cinerarias* Mr. T. Wheeler was first, and for *Primula sinensis* Mr. Larke was first. *Bulbs* in this class were very good, Mr. G. McDougall winning the twelve *Hyacinths*, which were excellent, included *La Grandesse*, *Koh-i-noor*, *Mont Blanc*, and *Giganteus*. The former

exhibitor was also first for six pots of single *Tulips*, three in each pot, and also first for double *Tulips*.

Cut flowers and table decorations were an important feature of this class, and quite equal to those in the open class for nurserymen. Seven drawing-room epergnes were exhibited. Mr. J. Battensby, Swallowwell, was first with the usual flowers used, the upper and second tiers of the Marsh stand, but the base rather heavy in comparison. Miss Edmondson and Miss Oliphant were second and third each.

Hand bouquets were also well shown. Amongst six staged Mrs. J. Jennings was first; only white and dark *Roses*, *Lily of the Valley*, with *Maidenhair Fern* were used. This caught the eyes of the Judges, and had a most pleasing effect, although more valuable flowers were in many of the others.

Some fine stands of spring blooming plants were shown by Messrs. John Hood & Co., Elswick Road, Newcastle, and Mr. H. H. Hillar, florist, Darlington; Messrs. W. Flynn & Co., 3, Stockton Road, Sunderland, stands of seeds; and Mr. W. R. Armstrong, Benwell.

The arrangements for the Show by the Committee were excellent. The staging was done by Mr. J. Hood, jun., of Elswick Road, Newcastle, who carried his work out in a very able and practical way; this work was hitherto done by the Committee, but the above arrangement has been found to answer much better. The late Secretary since entering the Newcastle Council has retired and is succeeded by his nephew, Mr. J. G. Gillespie, B.A., LL.D., and must have been most gratifying to him the success that has attended the first exhibition he has supervised.

## ROYAL BOTANIC SOCIETY.

APRIL 26TH.

THE second spring Show of the Royal Botanic Society was held in the gardens at Regent's Park on the above date. Beautiful weather prevailed, and the Exhibition was of a bright and diversified character. The competitive classes were well filled, and there were some fine miscellaneous exhibits. *Roses*, as are reported below, were well represented, and in consequence much admired by the numerous visitors. The same may be said of hardy plants, and the groups of flowering and foliage plants, the latter forming quite a feature in the Exhibition.

Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea, had a splendid group of flowering shrubs and miscellaneous plants. This comprised *Azaleas* in variety, *Cystisus Scoparius*, *Andreas*, *Acers*, *Wistaria sinensis alba*, *Andromeda speciosa cassinefolia*, *Liliums*, and *Spiræas* (large silver medal). Messrs. Veitch also had a box of *Streptocarpus*, a pan of *Vriesia McCrei*, and *Strobilanthes Dyerianus*. Messrs. W. Cutbush & Sons, Highgate, sent plants of *Little Gem Calla*, *Leschenaultias*, and *Abutilon Souvenir de Bonn*. Messrs. J. Laing & Sons, Forest Hill, S.E., staged a magnificent group of flowering and foliage plants, including a new *Caladium* named *Ibis Rouge*, and *Louis Van Houtte*, and *Calla aurata* (silver medal). Messrs. J. Peed & Sons also sent a well arranged group of stove and greenhouse plants tastefully arranged (silver medal). These groups were arranged in the corridor, and being in such a conspicuous position, naturally attracted attention.

*Roses* were splendidly shown by Messrs. W. Paul & Sons, Waltham Cross, the plants being excellently flowered. Half a dozen boxes of cut blooms were also sent by this firm, the flowers being fresh and delightfully fragrant. The *Tea Rose Corinna* was most conspicuous in this exhibit (large silver medal). Messrs. G. Paul & Sons, Cheshunt, likewise had *Roses* and a new dwarf *Canna* named *Primrose* (small silver medal). Messrs. Hugh Low & Co., Clapton, were represented by a group of hardwooded plants (silver medal); and Messrs. J. James and Sons, Slough, sent well-flowered *Calceolarias* (small silver medal). Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, had a grand group of single and double *Begonias* in pots (silver medal). Mr. Ware also had some yellow *Carnations* named *Pride of Britain*, *Tree Pæonies*, and other border flowers (small silver medal). Mr. A. Knowles, Horsell Nursery, plants of *Daphne cneorum majus* (bronze medal). This is a very dwarf growing form with small pink flowers very sweetly scented.

Mr. G. Perry, gardener to J. C. Tasker, Esq., Brentwood, had a group of pot *Roses* and *Cannas*, all well flowered (silver medal). Messrs. H. Lane & Sons sent the *Azaleas* which were shown at the Drill Hill (bronze medal). Mr. J. Pike, South Acton, a small group of *Carnation Uriah Pike*. Messrs. Peter Barr & Sons, Long Ditton, staged a collection of *Narcissi* and hardy cut flowers (large bronze medal), and a number of mixed *Tulips* (bronze medal). Mr. J. Walker, Thame, had *Maréchal Niel* blooms and *Zonal Pelargoniums* (bronze medal). The *Roses* were richly coloured, and the *Pelargoniums* were exceedingly bright.

Messrs. G. Paul & Sons were first for six pot *Roses*, showing grand plants of *Alphonse Soupert*, *Violette Bouyer*, *Baron N. de Rothschild*, *Céline Forestier*, *François Levet*, and *Heinrich Schultheis*. Mr. W. Rumsey, Waltham Cross, was second, who also had a grand collection of *Roses* in the miscellaneous classes (silver medal). Mr. R. Scott, gardener to Miss Foster, The Holme, Regent's Park, secured first prize for six *Clivias*, the same exhibitor being also first for six *Dielytra spectabilis*. Mr. J. Douglas was first with twelve *Amaryllises* and nine *Cinerarias*. Mr. T. S. Ware was awarded first prize for twelve *Begonias* and twelve pans of *Primula Sieboldi*, and for a collection of herbaceous plants. The *Primulas* made a rich display, the plants being covered with blooms of various shades, and the hardy plants made a most interesting feature.

Mr. Scott secured first prize for twelve greenhouse *Azaleas*, showing

well-flowered plants. Mr. Eason, gardener to B. Noakes, Esq., Highgate, was second; and Messrs. J. Peed & Sons third. Mr. Scott was also first for twelve Spiræas; Mr. W. Morle, Fenchurch Street, E.C., being second; and Messrs. J. Peed & Sons third. Mr. Morle was first with twelve pots of Mignonette; and Mr. A. White, Stanmore Park, second.

Alpine Auriculas were best shown by Mr. C. Turner, Slough, in the class for twelve plants, Mr. W. L. Walker, Reading, being second, and Mr. J. Douglas third. Mr. Douglas was first, however, for twelve plants of various types; Mr. A. J. Sanders, gardener to Viscountess Chewton, being second. Messrs. C. Turner secured a silver medal, and J. Douglas a bronze medal for a group of Primulas and Auriculas. These exhibits comprised all the leading varieties, and the plants were shown in grand condition.

Messrs. G. Paul & Sons were first for a collection of alpine plants, and the Guildford Hardy Plant Nursery Company second. Messrs. Paul's plants were in pans, whilst those from Guildford were tastefully arranged in baskets, and staged thus excited much interest.

Certificates were awarded for Auricula Engineer shown by Mr. C. Turner and Mr. A. J. Sanders; Carnation Uriah Pike, Mr. J. Pike, South Acton; Azalea Raphael de Smet, Messrs. H. Lane & Son; Iris Hellæa, Mr. T. S. Ware; Auricula Tonjours Gaie, Mr. J. Douglas; Azalea Anthony Koster, Strohilanthes Dyerianus, Lælio-Cattleya Ascania, Lælia Latona, Vriesia Morreni, and Wistaria sinensis alba, Messrs. J. Veitch & Sons; Caladium Louis Van Houtte, Messrs. J. Laing and Son; Stanhopea Amesiana, Messrs. Hugh Low & Co.; Double Begonia, Miss Jennie Fell, Mr. T. S. Ware.

### ROYAL METEOROLOGICAL SOCIETY.

At the last monthly meeting of this Society, Dr. C. Theodore Williams, President, in the chair, Dr. R. L. Bowles, Miss E. Brown, Dr. W. C. Falls, Mr. R. Lamont, and Mr. A. R. M. Simkins were elected Fellows of the Society. The following papers were read:—

1, "The Direction of the Wind over the British Isles, 1876-80," by Mr. F. C. Bayard, F.R.Met.Soc. This is a reduction on an uniform plan of the observations made twice a day, mostly at 9 A.M. and 9 P.M., at seventy stations during the lustrum, 1876-80, and the results are given in tables of monthly and yearly percentages.

2, "Notes on Two Photographs of Lightning taken at Sydney Observatory, December 7th, 1892," by Mr. H. C. Russell, F.R.S. These photographs were taken with a half-plate view lens, mounted in a whole-plate camera, and as a matter of course there is some distortion at the edges. Both photographs show the gaslights in the streets as white specks, the specks being circular in the centre and crescent-shaped in other parts of the plate owing to distortion. The lightning flashes are also distorted. Mr. Russell believes that this distortion may account for the so-called "ribbon" flashes which are seen in many photographs of lightning. He has also made some measurements of the length and distance of the flashes, and of the intensity of the light.

3, "Notes on Lightning Discharges in the Neighbourhood of Bristol, 1892," by Dr. E. H. Cook. The author gives some particulars concerning two trees in Tyntesfield Park which were struck by lightning, one on June 1st, and the other on July 18th, and also some notes concerning a flagstaff on the summit of Brandon Hill, which was struck on October 6th.

4, "Constructive Errors in Some Hygrometers," by Mr. W. W. Midgley, F.R.Met.Soc. The author, in making an investigation into the hygrometrical condition of a number of cotton mills in the Bolton district, found that the mounting of the thermometers and the position of the water receptacle did not by any means conform to the regulations of the Royal Meteorological Society, and were so arranged that they gave the humidity results much too high. The Cotton Factories Act of 1889 prescribes the maximum weight of vapour per cubic foot of air at certain temperatures, and the author points out that if the instruments for determining the amount present in the mills have an error of 20 per cent. against the interests of the manufacturer it is necessary that the makers of the mill hygrometers should adopt the Royal Meteorological Society's pattern for the purpose.

### GRAFTING: DOES THE WOOD OF THE STOCK AND SCION UNITE?

THE Journal for the 6th inst. contains a letter (page 272) from Mr. H. Dunkin, putting the question, Does the wood of the scion and stock unite? Your note to the letter bears that no union of the heart-wood takes place.

Ten or twelve years ago I had occasion to take up two standard Morello Cherry trees grafted on the Mahaleb stock, they were a little over twenty years of age. A section was made through the graft, which apparently shows the wood to be quite solid, both before and after the graft. I have sent you one of the sections to enable you to judge for yourself. The other half of the stem was sent some years ago to the Museum of the Botanic Gardens in Edinburgh at the request of the Curator.—M. G. F.

[The section of grafted Cherry wood which we have received is a very handsome one, having a diameter of 6 inches below and 4 inches above the point of union between the stock and the scion. It illustrates

clearly how, despite the organic incorporation of the two, the character of each wood remains distinct on both sides of the line of grafting. We cannot admit, however, that there is organic incorporation to the very centre, or, as our correspondent expresses it, "that the wood is quite solid before and after the graft." It is certainly solid enough after the graft, as the 3 inches of compact timber on each side of the grafting scar testify. So great, indeed, is this in its amount and its power of compression that it reduces to insignificance the original heart-woods of the scion and the stock. They can still, however, be discerned merged in a brown cicatrix at the centre, but it is a mechanical approximation merely, and preserved by the constrictive force of the superadded rings of new wood. Were these removed the original heart-woods would fall asunder of themselves, as they are decayed and penetrable by a sharp

FIG. 64.—SECTION OF A GRAFTED CHERRY.

pointed instrument. From this we are justified in reasserting our conviction that, though there may be some union between the woods of the stock and the scion, it does not extend beyond the softer outlying portions which merge into the alburnous layer, and that the heart-woods remain distinct and ultimately degenerate as their vitality expires. The illustration (fig. 64) is from a photograph (reduced) of the section above referred to.]

### TRADE CATALOGUES RECEIVED.

G. Bunyard & Co.—*Hardy Herbaceous Plants, Pot Roses, Bedding Plants, &c.*

E. H. Krelage & Son.—*Herbaceous Irises.*

G. Phippen, 108, Broad Street, Reading.—*Bedding Plants and Dahlias.*

Toogood & Sons, Southampton.—*Farm Seeds.*

B. S. Williams & Son, Victoria and Paradise Nursery, Upper Holloway.—*New and General Plants.*

## FRUIT FORCING.

**Vines.**—*Early Houses.*—A dry atmosphere in result of incessant firing and the necessity of withholding the customary dampings when the fruit is advanced in ripening encourages red spider, and, as this pest spreads with alarming rapidity where it obtains a footing under such conditions, prompt steps must be taken against it. Water is undoubtedly the best preventive of red spider; but the application of water to Vines by the syringe, even when clear soft water is used, is destructive of the bloom, and in some cases leaves a deteriorating mark where the water hangs on the berries. If a sharp look out is kept on the foliage, and whenever the smallest patch of brown appears to be caused by red spider, and the part is carefully sponged with a soft soap solution, 2 ozs. to a gallon of water, the pest will be prevented from spreading. The Vines will be kept in health until after the crop has been removed, when recourse can be had to insecticides, and the eradication of the insects by syringing. As future crops depend upon the preservation of the foliage in health, early attention to this work is imperative. Where Grapes are swelling a careful examination of the border should be made, and if the inside or outside borders (the latter, in some cases, being unusually dry for the time of year through the prolonged drought) are dry, a liberal application of tepid liquid manure will be a powerful aid to the Vines and inimical to red spider.

Grapes now colouring will require abundance of warm air by day and night, with plenty of moisture on the paths, walls, and border, but avoid keeping the latter constantly saturated. Gradually reduce the night temperature as the berries ripen, keeping the atmosphere cool and rather dry, yet not arid, for the Grapes will keep better with moderate air moisture, provided it is not stagnant, the temperature being kept at about 60° at night. The soil also must be kept in a moderately moist condition, early Vines requiring much more water after the fruit is ripe than late ones. If fermenting materials have been employed on outside borders, remove them gradually, leaving a light mulching only of the most suitable, the partially decayed, for the protection of the surface roots, and allow them to have exposure to the summer rains, which will wash in the fertilising elements of the mulching and promote root action, stimulating the Vines into the production of new laterals after they are relieved of the crop, these preventing the premature falling of the foliage and consequent starting of the principal buds.

*Midseason Houses.*—Proceed with tying down the growths, stopping the shoots and laterals, and attend to thinning the bunches and berries. If a large percentage of the surplus bunches were cut off before they flowered there is likely to be a better set of Grapes than where they were left until the flowering is past. Allow an even spread of foliage over the space at command, but avoid crowding, yet the more leaves a Vine has the more food it will assimilate contingent on their being in a position to do so—that is, are fully exposed to light and air. Supply liquid manure to inside borders, also outside when needing moisture, and mulch with a little lumpy manure, renewed from time to time so as to maintain about an inch thickness. Nothing answers better than horse droppings for heavy soil, but they must be sweetened, otherwise the ammonia evolved will be too powerful for the tender foliage of the Vines. For light soil cow manure is better, drying it a little before use, so as to have it rather lumpy, for a close surface prevents the access of air and the food elements are liable to become effete. Ventilate early—a little by the time the sun acts on the house, and increase it with the rising temperature, closing sufficiently early for the latter to rise it to 85° or 90° with plenty of atmospheric moisture, and if there is too great an accumulation of it a little ventilation given at the apex will allow the vitiated air to escape and prevent excessive moisture being deposited on the foliage.

*Late Houses.*—April has been everything the Grape grower could desire—not cold and plenty of sun—and late Vines have started well and are making rapid progress. Disbudding must be attended to, leaving no more shoots than there is room for, not being in too great a hurry in tying down the growths, yet not allowing them to touch the glass, and stopping them to within three or four joints of the fruit. The best time to do this work is the latter part of a fine day when the growths are limp through the evaporation and the warmer and drier atmosphere. Fertilise Muscats and other shy setting varieties every fine day when they come into flower and the “caps” are being thrown off or easily removed, choosing the time when the temperature has reached its maximum and air has been admitted for an hour or two.

*Late Hamburghs.*—Where these have been allowed to start naturally they will be in a condition to require disbudding, tying down, and regulating the growths, stopping not less than two joints beyond the show of fruit—preferably a joint or two more where there is room. Pinch the laterals at one joint below the fruit, above also where the space is limited, otherwise allow them to extend so as to insure an even covering of the space with foliage that can have exposure to light, afterwards keep closely stopped. Commence ventilating early and freely to secure

short-jointed sturdy wood and stout leathery leaves. Avoid a saturated condition of the atmosphere, as that only tends to soft growth, and is further accelerated by a soapy state of the soil. A light mulching of lumpy manure or loam will encourage surface roots, save watering, and in some cases greatly benefit the Vines by causing them to emit roots from the stem at the collar.

*Newly Planted Vines.*—When the Vines have recovered the effects of planting they will grow freely, and therefore aim at a sturdy and short-jointed growth, with thick leathery leaves of a healthy bluish green colour. Take advantage of sun heat to increase the ventilation early in the day to get the food elements well elaborated, aiming more at food stored than an extensive growth; stopping laterals at the first leaf and the cane when it has made 8 or 9 feet of growth, taking every possible care of the main leaves, not allowing them to be interfered with in any way by the laterals. Keep the soil moist, but rather under than over wet, and close early with plenty of atmospheric moisture.

**Melons.**—The fruit in the early house now ripening will require a drier atmosphere in order to secure high flavour, ventilating a little at night, for pent up air does not favour colouring and quality, but is likely to cause the fruit to crack. In houses where the fruit is swelling the night temperature should be maintained at 70°, 70° to 75° by day artificially, ventilating at 75°, increasing it with the heat, and maintaining through the day at 80° to 85° or 90° from sun heat, and close the house about 3 P.M. or earlier, so as to run up to 90°–100° with plenty of moisture. Add more warm soil to the hillocks or ridges as the roots push through their sides, which must be repeated at intervals until the allotted space is filled, pressing it firmly. Young plants must not be allowed to become pot-bound before being planted, or they become stunted and rarely make a free satisfactory growth afterwards. Any that are likely to get into this state should be shifted into pots 2 inches larger in diameter than those they are at present in, so as to keep them in steady progressive growth until the hillocks are got ready for them. Sow seed to raise plants for successional planting.

**Cucumbers.**—Syringe the plants in hot-water heated pits or houses twice a day, so that every part of the foliage may be kept free of red spider, but it must be done without damaging the leaves, which are very brittle and easily injured. Plants in full bearing require liberal and frequent applications of liquid manure at a temperature about the same as the bed, but do not supply it so as to cause a soft growth. Avoid crowding and overcropping. Use no more fire heat than is absolutely necessary, yet the temperature must be maintained at 65° to 70° at night, and 70° to 75° by day artificially, and as the fire heat is lessened less moisture will be required, and must be reduced accordingly. Attend to the necessary stopping, thinning, and tying of the shoots, keeping up a succession of fruitful growths. Straight fruit are finer looking than crooked; where the first are in request the fruit should be placed in glasses as soon as fairly set and the flower kept on, or three pieces of board nailed together so as to form an open-ended trough, make a good substitute. Make sowings or plantings as necessary to maintain a supply of fruit exceeding rather than unequal to the demand.

Plants in pits and frames should be frequently seen to for the regulation of the growths, keeping them rather thin, stopped one joint beyond the show of fruit, and removing bad leaves as they appear. A sprinkling at closing time will be sufficient for these plants, not allowing them to suffer through lack of moisture at the roots, nor supplying water until it becomes necessary, for a sodden soil is destructive to the roots and induces canker and gangrene, which sometimes affects the fruit and renders it unwholesome. Ventilate early, increase it with the heat, and close early in the afternoon so as to maintain a good temperature well into the night. Attend to the linings, taking care to avoid rank steam getting into the frames or pits, and employ covering over the lights for some weeks longer, or until the weather becomes so warm that the night temperature of the frame does not fall below 65°.

## THE KITCHEN GARDEN.

**Brussels Sprouts.**—If this important crop is liable to fail early, then ought more seed to be sown in the open; these late-raised plants, duly put out in good ground, frequently producing excellent late sprouts. All raised under glass ought to be pricked out about 4 inches apart on somewhat sheltered borders, the soil of which has been well pulverised. Exceptions may be made to this general rule in favour of any raised rather late and thinly; these, if not unduly coddled, being quite strong enough to be dibbled out where they are to remain for the season. The latter is the least laborious plan, as those pricked out have to be transplanted with a trowel the next time they are moved. Brussels Sprouts pay well for liberal culture, and should have a fairly rich and deep root run, this being made rather firm for them, and the plants be put out in rows, if the varieties are strong growers, 3 feet apart and 2 feet asunder in the rows. On poorer ground, or if the varieties are of a neat habit of growth, Paragon and The Bullet not requiring much room, the distances may be 30 inches and 18 inches respectively. The usual practice, however, is to dispose them between early Potatoes widely planted directly the latter are moulded up.

**Early Broccoli.**—A good batch of these, notably Veitch's Autumn Protecting, should be raised under glass, and treated in every way similarly to Brussels Sprouts, only given rather less room, the rows being 30 inches apart and the plants 2 feet apart in the rows; or these may also be grown between widely arranged rows of Potatoes. There is no such thing as making these early Broccoli really frost-resisting, but they are of the greatest value for lifting and storing under glass, and therefore should be grown most extensively and well. If sufficient

plants of the variety named are put out a good supply of hearts of superior quality can be had from the time autumn Cauliflowers are over till February, always supposing ample protection from frost is afforded. Late-raised plants, or any obtained by sowing seed in the open during April or the first week in May, not unfrequently prove exceptionally profitable at midwinter and later.

**Cauliflowers.**—Those put out under hand-lights, and also quite in the open and roughly protected, have made good progress, the extra warmth in the soil, coupled with help from the watering-pot, suiting them well. They will be wanted, too, earlier than usual, owing to the Broccoli turning in so rapidly; and liquid manure ought to be given them directly they shows signs of hearting. This will expedite growth, and also considerably increase the size of the hearts. Any raised thinly in boxes or beds of soil under glass, and well hardened off, may well be dibbled out where they are to remain, and thus treated are less likely this season to heart in prematurely than will be the case if pricking-out into nursery beds, and then transplanting, has to be resorted to. Not many summer Cauliflowers are wanted, but no mistake is often made in the direction of growing too many plants of the Autumn Giant. Treat plants of this variety that were raised under glass similarly to the Autumn Protecting Broccoli, and if more seed is sown now, the plants obtained will, if planted on good ground in succession to early Potatoes, afford a supply of acceptable late hearts, especially if roughly protected. Eclipse is the only other variety worthy of being sown at this late date, and grown alongside the Autumn Giant will heart in from ten days to a fortnight earlier than that old favourite.

**Borecole.**—There is no necessity to raise any of these under glass, or in many cases very early in the open. Instead of sowing seed thickly in beds and either pricking out the seedlings or allowing them to stand about long enough to become very leggy before they are put out, the wiser plan is to sow the seed late in April or early in May thinly in drills and well in the open. By the time the plants are fit to set out the sites are usually ready for them. Read's Hearting, though not particularly hardy, ought always to be grown owing to the very superior quality of the hearts, while the Asparagus Kale is worthy of being cultivated owing to its hardiness, good quality, and productiveness late in the spring. The last named answers well when sown during May in drills where the plants are to remain. The drills need be no more than 20 inches apart, and the plants may be left rather thickly in the rows.

**Midseason and Late Broccoli.**—The remarks anent sowing Borecole too early also apply with even more force to midseason and late Broccoli. Unless early raised plants can be put out quickly they soon become drawn, and leggy plants are the worst to deal with and the first to succumb to frosts. The end of April or early in May is also the best time for sowing Snow's Winter White Broccoli. Raised and planted out much earlier the plants are liable to attain a great size and produce nothing but quite worthless hearts. In each and every case open drills rather thickly, well moisten them if at all dry, then sow the seeds thinly and level over. The seed will germinate quickly this season, and serviceable plants be had without much further trouble. If birds are troublesome either roll the seeds first in a damp cloth and then in powdered red lead prior to sowing, or else net over after they are sown. Slugs and the Turnip flea should be kept off by means of occasional dustings over of the tiny seedlings with a mixture of soot and lime.

**Chou de Burghley.**—This, again, is liable to grow far too rankly to be serviceable when raised and put out early, but if the seed is sown in the open now, and there be no undue delay in getting out the plants, Chou de Burghley will be found one of the best winter vegetables that can be grown. The other "hybrid" Cabbages may be similarly treated.

**Savoy.**—These rank among the most popular of winter vegetables, especially if not grown too strongly, extra large close heads not being nearly so much appreciated as those smaller and not so close and blanched. Raising and planting early is also very likely to result in most of the varieties being ready for use long before they are wanted, spoiling accordingly. If Tom Thumb, Dwarf Elm, Dwarf Green Curled, and Drumhead Savoy are sown now, and the seedlings receive fair treatment, the first-named will be ready for use quite as soon as usually required, and the rest will afford a good and long succession.

**Other Seeds to be Sown.**—The Extra Early Milan Turnip succeeds well on a south border, but in order to have the milder and more tender Snowball and Veitch's Red Globe good, these ought to be sown either on an east border or on ground partially shaded by fruit trees and bushes. Now is a good time to sow Carrots in variety, and also Beet, Chicory, Salsafy, and Scorzonera. All form the cleanest and straightest roots when sown on freely working ground, well manured for the previous but not these crops, contact with solid manure causing the tap roots to fork. The rows of Horn Carrots should be 10 inches apart, the other varieties 12 inches, while 15-inch distances are suitable for all the other kinds named.

#### PLANT HOUSES.

**Ericas.**—Pot any plants of *E. hyemalis* that have started freely into growth and that need more root room. Drain the pots well, and use for a compost good peat and coarse sand. Do not disturb the old ball further than is necessary to remove the drainage. The soil should be pressed firmly round the ball so that water will not pass through the new material and leave the old dry. After potting place the plants on moist ashes in cool frames. Give abundance of air daily, so that they will make a firm sturdy growth. Water carefully at first, and keep the plants moist as long as possible before giving them water at their roots

by gentle syringings and amongst the pots. Give the plants light shade for the first ten days or a fortnight after repotting them.

**Epacris.**—Repot plants that need more root room if they are in a healthy condition. Similar compost should be used in potting these plants as is needed for *E. hyemalis*. If the plants have been grown in cool quarters they may be placed in cold frames, but they do best when encouraged to make their growth by closing the frame early in the afternoon, syringing at the same time. Directly these plants are rooting freely in the new soil more air should be given them, so that their growths are firm and sturdy. It is a mistake to shade too long or to grow the plants in a close confined atmosphere.

**Hardwooded Heaths.**—All plants that need tying should be attended to without delay. Do not use more stakes than are absolutely necessary. Water with care, but do not allow these plants to become dry at their roots. Any plants that are required to flower late may be retarded by placing them in a cool airy house with a northern aspect. Young plants should have strong growths that are taking the lead drawn towards the rim of the pots so that the weaker ones will gain strength. Any flowers that show on these young plants should be removed at once if the object is to grow them as rapidly as possible.

**Azaleas.**—Remove the seed pods from Azaleas as they go out of flower, and place the plants where they can be kept close and moist to induce them to make a good growth. These plants, if they need more root room, may be repotted now. They do well in good peat and coarse sand, or may be grown satisfactorily in leaf mould that has not been heated and fibry loam, with a liberal addition of coarse sand. Material of this nature must be free from worms, and pressed firmly into the pots. Before potting, examine the plants carefully, and if infested with thrip syringe them at once with a solution of tobacco water.

**Camellias.**—Shade, where practicable, all plants that are making their growth. Give them liberal supplies of water at their roots, and maintain a moist atmosphere. Any that are confined at their roots in pots or tubs should have weak stimulants every other time they need water. Soot water in a clear state will prove very beneficial.

**Cytisus racemosus.**—Plants that have flowered may be cut close back, and when they have broken into growth, repotted, if they need more root room. These plants do well in good fibry loam and sand; if the former is poor one-seventh of decayed manure may be added. Place the plants in cold frames, which may be closed early in the afternoon until the former start into growth, when abundance of air should be given them. Pinch the shoots of young plants to induce them to branch, and pot them if they need more root room.

**Coronilla glauca.**—Place young plants in cold frames and ventilate freely. If they need more root room put them into larger pots; the compost advised for Cytisus, with the addition of a little leaf mould, will suit them well. Pinch the shoots to induce them to branch, and continue to do so if any display signs of taking the lead. Syringe freely, because this plant is very liable to be attacked by red spider.

**Callas.**—Put young plants into 5-inch pots, and grow them cool, so that they will be ready for planting out soon and thus produce an early batch of flowers. Plants that are flowering feed with weak stimulants every time they need water, but those that have done flowering may be hardened and stood outside to rest.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### CORRESPONDENCE.

THE extremely fine weather on the 19th and 20th, when the night temperature was 48°, and the day temperature 72° and 73° respectively, has put action in bee-keepers as well as bees, the latter working as if it was midsummer, and the former examining stocks and making inquiry about them and their management.

"A Yorkshire Bee-keeper" sends me a queen to see if I can unriddle the cause of her laying eggs that produce drones only. The queen is evidently one of 1892, and owing to the extremely low temperatures of that year, she, like many others, never mated. I am in receipt of nearly a dozen letters of a similar nature.

#### PUNICS.

The writer of another letter says, "I have had to put on a second super to a stock of Punics, the first being nearly full of honey, drones flying, and everything just now like June. I am satisfied pure Punics are in no way inferior to hybrids." I hope other persons having their bees pure or crossed will send in reports.

#### DRONE-BREEDING QUEEN AND UNFED HIVES.

About the middle of April I observed many bees issuing from one hive with drone seals between their mandibles. It appeared a strong hive, and in a normal state; but that did not satisfy me, and an inspection was made. Two divisions of a storifying Lararkshire hive were well filled with bees, and every available drone cell had its egg, larvæ, or pupa, and there were moreover many

queen cells in their various stages, but, of course, containing drones only. I at once made a search for the queen, and removed her, knowing at a glance she was a virgin, throwing her carelessly upon the alighting board until I arranged the hive, then found her in the lower division. Had I been a novice, or a pupil under the modern school, could the inspection of that hive done other than prompted the following questions:—Am I being misled? how comes all this brood in these hives without stimulative feeding? why any bees at all? and how is it possible that in the clusters of queen cells raised the queen regnant could have deposited eggs in them?

In one hive the brood for queen-rearing was taken from a Punic prime swarm of 1892 completely filled with brood, newly gathered honey, and pollen; scarcely an empty cell, bees and drones hatching in great numbers. A second one in a Stewarton hive of three boxes, ready for supering; and the third one, the drone breeder; neither of them having been fed, yet they are full of brood, and overflowing with young bees, as are most of my other hives. It must therefore be conceded that my bees are either different from those of the moderns, or are better managed, or that they must acknowledge that "stimulative" feeding is a fad.

Another point, unfertilised queens deposit eggs at first in drone cells, and when these are filled they lay in the worker cell's one egg as regularly as if they had mated. When the bees were few I have witnessed a departure from this, which but proves the rule. On the contrary, fertile workers or imperfect queens incline to lay in worker cells first in an irregular manner, an experienced person being perfectly able by a glance to know which he has to deal with.

The drone breeder was a stock hive having sent off a swarm about the middle of June, 1892, besides having four of its brood combs removed. When inspected the hive had evidently lost few of its bees, which are now nearly ten months old. According to many of our modern bee-keepers they ought to have been dead last August. They will be living months hence.

#### TWO QUEENS IN ONE HIVE.

In addition to the above letters I have several inquiring about the two queens in one hive system, while some writers term it the "Wells" system. I have never observed that Mr. Wells claimed it as his system. It has been so described by others who either knew, or ought to have known, that the system is not, and that it did not originate with Mr. Wells. The foregoing are facts, affording matter for study and reflection.

Working two queens in one hive is at least half a century old. The keeping of stocks on the twin system originated in Scotland as a preservative of bees during winter before the wintering problem was solved. We can with perfect safety, with our system of ventilation winter very weak stocks. For example, a nucleus that was started 1st August last year, with not more than from 300 to 400 bees and brood cells combined, has with only 9 lbs. of sugar wintered, and is doing well. Bee-keepers, therefore, need not be apprehensive for the safety of their bees during severe winters when our instructions have been carried out.

The telescopic and convertible Lanarkshire hive, lately explained, was specially made for working two queens in one hive, but it had its drawbacks in some respects; it was unsuitable for moving to and from the Heather, although it was easily converted into a storifier. How much more unsuitable then for that purpose will a one-storeyed hive large enough for two prolific queens be? The bee-keeper to be successful ought to be prepared for every contingency. Huge hives tenanted with two queens are sure to swarm. When the bees of both queens are allowed to intermix indiscriminately extra hives must be in readiness.

With two Lanarkshire storifying hives in full strength a little before the commencement of the honey flow, and a little precaution to have both lots of bees gorged, they and the combs are united into one hive, with the exception of a nucleus, if desired, for raising, or rather nursing, a future queen. The young bees, after the two hives are joined, will be hatching from the cells in a greater ratio than the queen regnant can replace with eggs. These are simply the outlines of a system long and successfully practised. It must also be borne in mind that the advantage is not always on the side of the strong hive. In a poor honey season like 1892 the stronger the hive the less the honey. I can speak advisedly upon the subject and system I have so long practised; therefore, nothing is tentative with me, as it is with those who are claiming to be the diffusers of a "new" system.—A LANARKSHIRE BEE-KEEPER.

#### EARLY SWARMING.

THINKING it may interest some of your readers who are interested in bees, I can say that on April 21st I had a good swarm

of bees from an old-fashioned straw skep. As it is far earlier than ever I had one before in my experience of over forty years of bee-keeping, I thought it might interest someone.—A. ALDRIDGE, *Manor Farm, Petersham.*

## TO CORRESPONDENTS

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Calceolarias Diseased (G. F.).**—The disease is of a fungoid nature, and some varieties are more liable to injury than others. The plants sent have been much overcrowded, favouring the affection. Wednesday morning's letters can only be answered briefly, if at all, in the current issue.

**Definition of a Cottager (B. and D.).**—In some districts persons who do not pay more than a given amount in rent, and in others those who do not receive more than a stated amount in wages, are regarded as cottagers for purposes of exhibiting at shows. The amounts in both cases depend on the custom of localities.

**Culture of Gasterias (J. B.).**—Gasterias belong to the Aloe section of the Lilyworts. They are very neat plants for a succulent collection. They will do well in a house kept from 45° in winter to 60° and more in summer. They flourish best in sandy loam with a little peat and very rotten dry cowdung, and some lime rubbish and broken bricks—say, two parts sandy loam, half a part of cowdung, and half a part of broken bricks and lime rubbish. The chief care they require is to keep them almost quite dry when in a state of rest in winter. If the pots stand on a damp stone or damp gravel they will absorb enough moisture in the dark months.

**The Pistachia Nut (A. L. B.).**—So common and so much esteemed in the south of Europe, is the produce of *Pistachia vera*, a tree about 15 feet high, obtained originally from Syria, but now extensively cultivated in Spain, Italy, the south of France, and Sicily. The fruit is of the size and shape of an Olive, but convex on one side and concave on the other, and with a rougher surface. It has a tender, crimson-coloured pulp, which is rather sparing, and encloses a nut which opens with two valves, disclosing a greenish kernel covered with a red pellicle. These nuts are sweet and agreeable; they enter into the composition of ragoûts and other dishes, and are used for flavouring ices and creams, besides being preserved incrustated in sugar and other forms of confectionery. The best come from Arabia and Syria, but large quantities are exported from Sicily. They are said to be very nourishing and wholesome.

**Destroying Slugs (T. P.).**—The most simple and effectual method with which we are acquainted is to water the beds where the pests are so destructive with lime water; but it must be applied when they are feeding after dark, not when they are hiding in the daytime. A peck of "shells" or lumps of lime will be sufficient for thirty gallons of water, and it should stand to get clear. Slaked or powdered lime is of no use. There are scarcely any plants that will be injured by the lime water; on the contrary, the majority will be benefited by it, especially Box. If a line of moist tar can be spread between the orchard and flowers slugs will not cross it. If you will repeat your question relative to spring-flowering plants, and state whether you require them for growing in pots under glass or for planting in the garden, your letter shall have our attention. The lime water should be applied through a rosed watering pot, and it will destroy all the slugs that are drenched with it.

**Market Prices (M. I. D.).**—You ask "if the Covent Garden quotations given weekly are reliable, and actually obtained by salesmen and commission agents for their customers." The prices are as reliable as can be given for representing the average. The amounts are actually obtained by salesmen who, of course, deduct commission in remitting to the growers. But you must understand that the prices given are not the lowest on the one hand nor the highest on the other. Large consignments of so-called "goods" reach the market that are scarcely disposable at any price, and we have known salesmen send every penny they have obtained to the consigners with an intimation that no further supplies are needed. Some produce is essentially inferior, some is good,

but a week or more too late for insuring the best returns, while no small quantity is good when cut or gathered, but spoiled through bad packing. The very best fruit, flowers, and vegetables that reach the market at the earliest date in faultless condition realise higher prices than those quoted. The prices of perishable articles of necessity fluctuate extremely according to condition, and even produce of good quality falls quickly and considerably in value in an overstocked market. The averages are as fair as can be compiled on the spot; but it may be said that London is not by any means the best market at all times for garden produce of various kinds and necessarily differing quality. Respecting books, "The Pansy," by James Simkins (Simpkin, Marshall and Co.), is good. The price is not recorded in it. We have no work on the other subject in our library.

**Using Sulphate of Ammonia (Amateur).**—This is a very active plant stimulant, but by no means a complete manure. It will make almost everything to which it is rightly applied grow quickly, and will kill almost anything when used in excess. If it is used alone and continuously the soil must eventually become the poorer, because of the abstraction of phosphates, potash, and other ingredients from it through the accelerated growth. An ounce to the square yard is a fairly good dressing, twice that quantity a very liberal one, though we have known it exceeded to some crops without injury. Some soils are much poorer, and consequently need more manure than others. If you can mix twice the quantity of superphosphate of lime with the sulphate of ammonia, and apply at the rate of 2 ozs. to the square yard, you will have a better, cheaper, and more permanently satisfactory manure than by using the ammonia salts alone.

**The Sweet-scented Barbadoes Cedar (N. O. L.).**—*Cedrela odorata* is the Sweet-scented Barbadoes Cedar, a native of the Caribbee islands and Barbadoes. In the West Indies it is simply called "Cedar." The tree is upwards of 80 feet high. The flowers are pale flesh-coloured, and are like those of the Hyacinth; the fruit, bark, and leaves have the smell of assafoetida, but the wood is fragrant and agreeable. The trunks grow to an immense size, and are converted into canoes by merely hollowing them out; some of which, when completed, are as much as 40 feet long and 6 feet broad; and the wood being so soft and light, they carry a great weight on the water. The wood is of a brown colour, with a fragrant odour. It is much used as shingles for covering roofs, and is employed in ship-building, for which purpose it is ill adapted, on account of its liability to attacks from the worm. It is also used for wainscoting of rooms, and to make chests, because vermin do not so readily breed in it as in many other sorts of wood, this having a very bitter taste, which is communicated to whatever is put into vessels made of it, especially when the wood is fresh; and hence it is never made into casks, because the spirituous liquors would extract the resin, and thereby acquire a very bitter taste. In France the wood is employed for covering black-lead pencils, and it is said that the Havannah cigar-boxes are made of it.

**Stove Flowering Plants (J.).**—The *Eucharis* must be encouraged to make good growth; when completed the plants should be gradually kept drier at their roots, and then retarded in a cooler structure. After a good rest, without unduly drying the plants, they may, after introducing them into heat, be had in bloom in a month. The *Allamanda* should be encouraged to grow, for upon the growth made will largely depend the size and quantity of the flowers produced. These plants are practically continuous in their habit of flowering, and after the first growths show flower each shoot will branch again into three or four, which will flower again. Under good treatment and liberal feeding flowers are produced for at least eight months. *Clerodendron Balfourianum* should not be closely pruned back; all that is needed is the removal of the unripe ends of the wood of the previous season. From the time of starting about eight weeks only is required under proper stove treatment to bring the plants into good condition for exhibiting. It is just possible your plant may be too early, or it may not flower satisfactorily if you pruned it hard back, removing the greater portion of last year's wood. If plenty of flowering wood was left do not hurry the growth, and if it advances too early gradually give the plant cooler and more airy treatment. You may safely retard this plant during the month of July without fear of injury. When retarding carefully avoid cold draughts.

**Figs Decaying at the Apex (Delta).**—The fruits are infested with the spot fungus (*Glæosporium læticolor*, B.) It was first noticed on half-ripe Peaches and Nectarines by the late Rev. M. J. Berkeley, and it has been found on Apricots, Cherries, Figs, Grapes, and Plums. Its filaments (mycelial threads) penetrate to the seed or stone, and the flesh decays, in advance of a pale salmon coloured spot or patch, which appears on the surface near the apex or eye of the fruit. This consists of the reproductive bodies (conidia or spores) of the fungus, but they ultimately become brown or black. The fruit, especially Figs, generally falls. This points to the necessity of collecting and burning all attacked fruits. It is believed to be accelerated by a moist atmosphere, the moisture condensing on the fruit, and so causing a softening of the epidermal tissues, if not actual decay, and this leads to attacks of the fungus. It is a question of germs finding a fitting nidus, and it has been found that a little sulphur brushed on the hot-water pipes and a little air admitted constantly, with water withheld from the fruit after it commences ripening, or slightly in advance of that change, act as preventives of the fruit spotting and decaying at the apex. Burn all the affected fruits, withhold water from the others, and maintain a circulation

of warm, rather dry air constantly. The feeding and syringing would aggravate the evil; in fact, the fungus almost invariably attacks the finest fruits, and, as a rule, those that should be the first to ripen.

**Names of Fruits.**—*Notice.*—Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (H. H.).—A good and well kept fruit of Golden Noble.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in fern boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (G. A. C.).—*Triteleia uniflora*. (A Subscriber).—Probably *Doronicum caucasicum*; specimen insufficient. (X. Y. Z.).—An *Erodium*; specimen too withered to identify species. (A. M.).—*Adiantum pedatum*. (H. T.).—*Arpophyllum spicatum*. (F. D.).—*Ansella africana*. (L. E. G.).—*Woodwardia angustifolia*. (H. E. M.).—The parcel arrived as flat as a pancake, and the contents crushed. We can discern No. 2 as *Streptosolon Jamesianum*, but cannot identify No. 1.

#### COVENT GARDEN MARKET.—APRIL 26TH.

Prices remain the same, with a steady business doing.

Bedding plants in variety.

## HEAVY LAND.

VERY general are the complaints of heavy land farmers about the condition of clays ploughed after the heavy rain of February, and so hardened by the dry weather of March and April that a seed bed in it for spring corn has been an impossibility. This applies to clay land ploughed when saturated by rain water. We hear also of some ploughed earlier, then pulverised by frost, only to be beaten down to the consistency of putty by rain subsequently, and then hardened like paving stones upon the surface—a hard crust over the “putty,”—two extremes, part of it being too dry and hard, the other too wet and sticky for spring tillage. Even when rain falls again it will be no easy matter to get a seed bed in such soil, and its unkind condition must surely give rise to the query, Is it worth while keeping such land under the plough? We think it is not worth while, and invite attention to the alternative of either laying it down to temporary or permanent pasture, or to imparting such a degree of mechanical division to it as to render the hard crude condition of so much of it now an impossibility in the future.

Friability, or the property of crumbling easily, is an indispensable necessity in all arable land. To this plain fact we invite special attention now, while heavy land farmers regard their acres of hard clods with dismay. To any inquiry as to the cause of their difficulty the invariable answer is “The weather.” Strange indeed is it that no thought of soil amelioration ever seems to occur to those engaged in its culture, whose very bread depends upon good tillage, and who must be aware of the fickle nature of our climate. Yet from all parts of the country come letters complaining of the impossibility of corn sowing, some just complaining, others seeking advice. For the moment nothing can be done, but for the future a radical change may be wrought, in many an instance well known to us. Take for example Essex clays. With London so near with its daily output of thousands of tons of dustbin refuse, its daily clearance of stable manure under wholesome sanitary laws, the soil of that county, so favourably situated, ought long ago to have been rendered so friable and full of humus as to take rank among the best mixed soil. If this appears too large an undertaking—this dealing with an entire county, let us take some farms in it that are under the wise and sensible management of Scotch farmers. Under the six, seven, or eight years’ rotation they have most of it in temporary pasture, breaking up a moderate portion of it yearly. If to such land mechanical division was gradually imparted by dressing the portion to be ploughed heavily with the “ashes given away,” as may be seen on many a notice board in the metropolis, precisely the desired effect of perfect friability would be imparted to it.

In part ii. of the Journal of the Royal Agricultural Society for 1891, Mr. Primrose McConnell, in writing of his work on the Essex clays, says, “I must not omit to mention the part played by gas lime in ameliorating the soil. The action of lime on a clay soil is well-known, and in this district (Ongar), we use immense quantities of the spent lime from the London gas works, which we get at the cost of the carriage. It is applied in various ways, and many are foolish enough to use it without manure. Some mix it with earth for compost for top-dressings. We prefer to apply it raw, at the rate of from 4 to 6 tons per acre, in autumn, to the lea land that is to be ploughed up during the winter. By this means all ‘grubs’ are killed, the turf is partly killed, the soil is made more friable, while, of course, the natural fertility is stimulated. By itself

I have seen it act on a crop as strongly as nitrate of soda, but the soil must be fed along with it. Its effect on the mechanical texture of the soil is wonderful. I remember one case of a field that was partly dressed and partly left undressed with it, and in broadcasting the seed afterwards I could feel the difference in the soil in stepping from one part to the other every time I went up and down the stretches, because the limed part was so loose and friable.”

Lime, pit sand, road sand, coal ashes, slag, gravel, burnt clay, charcoal, wood ashes, mortar rubbish, any and every available substance containing hard particles to impart mechanical division to the clay should be used. Not always from carelessness is it that ashes are not used. Repeatedly have we had to overcome the popular idea that coal ashes are poisonous to soil. Of course the idea is absurd; but there it is, an absolute stumblingblock to many of those we so earnestly desire to help. It is probably some such idea which prevents farmers in the coal districts from using some of the fine slag from blast furnaces. We have recently seen huge heaps of such slag near ploughed land where mechanical division was evidently much needed.

## WORK ON THE HOME FARM.

In such a dry spring manuring for Mangold by using farmyard manure in the furrows will go far to promote vigorous growth immediately after seed germination, because the large per-centage of moisture in the manure prevents the young plant suffering from drought. It grows so quickly, with its first roots spreading among the manure, that it is soon out of harm’s way. To this brisk growth the superphosphate and nitrate of soda sown with the seed contribute, and when the plant is thinned a surface dressing of the nitrate proves a good investment, the vigorous growth being so well sustained that an exceptionally heavy crop is a certainty. If Mangold is grown at all it is a crop that well repays all we can do for it by early sowing, by liberal manuring; but thinning the plant as soon as it is large enough, and by such a free use of hand and horse hoes as leaves the crop a clean one when the leaves meet across the space between the rows.

As usual, early sowings of Swedes will follow the Mangold sowing. This has long been a rule in Norfolk, and so far as we have seen it followed in other counties it has answered well. For this crop of Swedes we prefer ridges prepared precisely as for Mangold, as there is then very little risk of losing plants from the dry weather common to May. Some mildew there may be among the early Swede, just as there will be a slight per-centage of plants bolting to seed in the early sown Mangold; but neither of these blemishes are sufficiently bad to be worthy of serious attention. The later crops of Swedes are sown on the flat, a well drained free soil being chosen where the crop is to stand over for folding when the lambs are strong enough to go out with the ewes upon them.

We used to make an early sowing of White Turnips in May for use in August and September, when pasture herbage so often falls off. But since growing green Maize it has been used as a capital substitute for the Turnips, both as being a more certain, more nutritious, and much more productive crop. Both crops require rich land; of the two the Turnips involve more labour in thinning and hoeing, and the result is not nearly so certain as it is with Maize.

## METEOROLOGICAL OBSERVATIONS.

## REMARKS.

16th.—Bright sunshine in morning, clouded over in afternoon, spots of rain in evening.  
 17th.—Overcast throughout, with a little rain early, and frequent drops of rain till about 11 A.M.  
 18th.—Bazy, with faint sunshine.  
 19th.—Warm with bright sunshine throughout, cloud in evening.  
 20th.—Thunder from 6.50 to 7.10 A.M., followed by rain; foggy and thick from 9 to 10 A.M., then bright sun till 4 P.M., cloudy after, and thunder at intervals from 4.15 P.M., and raining from 6 to 7 P.M.  
 21st.—Almost cloudless throughout.  
 22nd.—Bright and sunny throughout.  
 A remarkably warm week, with enormous daily ranges of temperature, reaching 32.3° on the 20th. The maximum of that day, 78.2°, has not been equalled in April since 1874, on the 23rd of which month it reached 79.2°—G. J. SYMONS.

TWO years ago come June a writer in the *Journal of Horticulture*, fresh from a visit to a Tulip bed that impressed him—not one of those glowing masses of yellow, crimson, or rose produced by early bedding Tulips in parks and gardens in April and May—but the Tulip bed of an old florist, thus recorded his impressions:—“There are Tulips from many collections in England and several from continental sources, but there is no mistaking the superiority in form, substance, and accuracy in colouration of the best of the English florists’ Tulips over all others that are grown in comparison with them. The ‘amateurs’ Tulips, as they are called on the Continent (the equivalent term to our florists’ Tulips) are in general appearance attractive, and the colours of some compel admiration; but in most of the blooms these colours are where they ought not to be, running right down to the base of the petals, and in some other respects irregular. Many of the petals are also too long pointed and flimsy, lacking the close cup-like shape and stout texture of the best English forms. These, too, are clearer at the base, as if a sun was set at the bottom of the bizarres and the most silvery of moons in the roses and bybloemens lighting up the colours of the flamed and feathered petals there displayed in beautiful regularity and indiscriminate hues.”

Taking up the theme and observing the striking and well-defined characteristics of our home-raised flowers, as developed and established by generations of florists, another writer last year went on to say:—“Since Conrad Gesner brought *Tulipa Gesneriana* from Constantinople more than 300 years ago marvellous work has been accomplished by hybridisers in various countries (with that species as a parent), but it is in England that the properties which are most esteemed in the best Tulips of to-day—perfect form, smoothness, substance of petal, and clean base—were developed. There are florists’ Tulips in abundance that possess none of these qualifications, and the time has come for finding some distinctive appellation for the noble class of flowers which pay tribute to the English florists’ skill.” The natural and just name foreshadowed was thereupon adopted—“English Tulips.” The distinction is the more called for since many of the “amateur” or florists’ Tulips of the continent come of a different race.

The overwhelming majority of Dutch florists’ or amateurs’ Tulips, effective as they may be for garden decoration, are wholly distinct from and distinctly inferior to the highest type of Tulips that have not been “made in Germany” (or rather Holland) but in England. This is plainly seen when extensively grown in comparison, as in Messrs. Barr & Son’s collection, and to a more limited extent in many private gardens. It is important that this should be known and the essential differences between what may be termed home and foreign flamed and feathered varieties recognised now that a demand is increasing for Tulips that combine brilliancy with chaste refinement such as is represented in the florists’ forms of *T. Gesneriana*. These are usually in full beauty in May, sometimes June, but this year they were fully expanded in the south of England during the last week in April. Beds of these Tulips shaded with canvas remain attractive for a month—a veritable floral feast, fascinating and unique.

If this is so it may be asked, “Why are not these late English florists’ Tulips more popular? why are collections of them so few

and far between?” There has been no attempt to popularise them, but somewhat the reverse. Connoisseurs as a body have valued them for their rarity, and have not willingly let them “go.” It is not surprising in one important respect that this should be so. The highest forms are regarded by those who possess and love them as precious gems not to be entrusted to persons who do not understand them, and who cannot appreciate what they represent—years of unremitting care in their preservation following years of waiting, first for the flowering of seedlings and the then longer time of breaking from the self or breeder stage into the flames of colour or feathered fringes that come to stay, and give life-long pleasure to those who own and cherish them. There is not much wonder that they should be jealously guarded, and as far as possible kept in the hands of those who know their value instead of being scattered abroad and lost; and thus it is if a collection of real genuine English Tulips loses its owner in the course of nature, and the bulbs have to be dispersed, the cognoscenti travel far to see them, and mark them for their own, at least such as they desire and can secure. Of late floral pilgrims have wended their way to Petersfield, Hants, to obtain what they could of the late Mr. Lloyd’s varieties, Bentley and Barr, Hogg and Lakin, and Miss Lloyd knows who besides, have been down to share in the honour of preserving her father’s long-cherished flowers. There was no need to advertise them, and all have found new owners. How, then, under such circumstances can these genuine English Tulips, which are thus “run after” by owners of existing collections ever become popular, and the numbers of growers of them materially increase?

The choicer and rarer named varieties cannot be obtained and collections formed of them in a year or two; or in other words, persons who might, as several do, like to become growers of these remarkable flowers will have to do as their “fore-elders” did—start at the bottom of the ladder and steadily work upwards; but until recently it has been extremely difficult to make a start at all. Continental mixtures could be obtained, but these are not English, and do not form a good foundation; but inexpensive mixtures of real English Tulips are now procurable. Mr. Peter Barr has taken them in hand, and he is not the man to rest satisfied till he attains his object. The same energy, perseverance, and knowledge which, from the smallest of beginnings, resulted in the world-famed collection of Daffodils—flowers once unappreciated, and, as a rule, rejected from gardens, but now grown in most; flowers once rarely seen in markets, but now sold in hundreds of tons—the same untiring zeal by which so much has been accomplished in this once neglected family of bulbous plants is bound to have effect, if not to the same extent, yet in a very material way in inciting public interest in late Tulips.

Mr. Barr is evidently a believer in the dictum that the supply of anything good in itself creates a demand, and English florists’ Tulips have been obtained from various sources and increased at Long Ditton where they now number many thousands. The result has been encouraging, and the demand for bulbs last year has given an impetus to production. The start is at the bottom of the ladder, cheap mixtures of unnamed varieties in which flowers of sterling merit are included; in fact there are grades of merit, and steadily will these be recognised, the best flowers being noted and admired as their properties are appreciated; then still better will be sought for and named forms procured. In that way are florists made and collections of the flowers they love established. It is so in the case of all flowers. They are first liked, then understood, then become fascinating and make the lives of their owners better worth living. That is what flowers do, and Tulips not the least, and hence the desirability of encouraging a taste for an extension of culture of these among other flowers, which, if intelligently indulged in, can lead to nothing but good. In this work Mr. Peter Barr is worthily sharing, and he will not rest till he makes these Tulips “go.” He has, moreover, the active

co-operation of his son with true florist's instincts, and Mr. William Barr is destined to make his mark in the Tulip world.

The Long Ditton collection is in full beauty now. The plants are not vigorous nor the flowers large, as the long drought and abnormal heat have brought them out before the proper time; but the characters of a number of varieties are well displayed, and the collection, while full of interest to experts, affords valuable lessons for learners. Day by day, from far and near, come old florists' and young aspirants to view them. Every flower is scanned, its points noted, and merits or defects recorded. An hour to a bed may be termed a quick examination, and thus a long day may and is spent by many among Tulips. Good stocks of some of the leading named varieties are already established, while others are represented in yet small numbers, but increasing yearly. Among the *Roses*, *Aglais*, a fine stock, is charming in its translucency, and the same may be said of Middleton Maid; Alice is small but pure, a dainty gem; Modesty, both flamed and feathered forms, is one of the loveliest; Lady Derby is splendid in form, pure, and beautifully marked; and Mabel is represented in goodly number, but there will never be too many of this delightful Tulip, for whether in breeder or broken form it commands admiration. Of the *Byblœmens* Lord Denman is in the greatest force; it is beautifully marked, but has not the clear basal disc that is desirable, and hangs down its head, still it is one to begin with; and to it those who can may add Storer's No. 2, of fine character; Agnes, stately and upright; Downie's Feathered, very chaste; Bessie, in feathered and flamed form; Chancellor, in three strains—Bentley's, dark; Douglas's, light and neat; Leach's Medium—all good; Duchess of Sutherland, very clear; Friar Tuck, fine form and chaste; Talisman, small, but perfect; and Mrs. Jackson, almost black, stencilled with silver. Of the more rich coloured *Bizarres* two dwarf forms, Caliph and Colbert, shone very brightly; Charles X., taller, darker, and good—a fine display; Royal Sovereign, a feathered form of the last named, splendid; Duke of Devonshire, bold and fine; Dr. Hardy, a fine stock of a grand Tulip; Everard, rich and glowing; Orion, very bright; George Hayward, a noble flower in splendid colour; Masterpiece, dark and well flamed; Pilot, bright, well marked, a fine stock; Sir Joseph Paxton, one of the best, Barr's strain, very fine; and Lord Stanley, of similar character. The varieties named are only a few of the notabilities at Ditton, and whoever is fortunate in obtaining them will have the nucleus of a good collection.

From these series of beds of named varieties and mixtures near Surbiton Station we are whirled to the Sussex coast to see the Tulip bed of an amateur—just one bed of sixty-three rows of seven plants each under a canvas tent, but something to remember. At Ditton there is a large collection; under this Sussex tent a choice selection of splendidly grown plants and magnificent blooms. Mr. Barr was so entranced that he had to rush home and send his son to gather hints and inspiration. Rose, byblœmen, and bizarre is the order of planting throughout, each in sequence from end to end of the bed; and the soft warm flush of the first, the purity and delicacy of the second, and the rich glow of crimson and gold of the third type, form a combination that can only be seen in these flowers. It is not only a difficult matter which to admire most, but hard to tell whether the breeder or broken forms of the same variety are the more beautiful. Take Mabel in its first stage, a shimmering rosy salmon with a spotless circular base; then take the flower when the white shoots up in silvery streaks and, so to say, crushes the body colour together in darker folds; both are alike beautiful, and can be looked at again and again. It is the same with purple selfs and the central silvery moons, which in due time break into byblœmens, and the dark reddish selfs with golden discs that develop into bizarres—the dark ground deepening when the yellow shoots through it in golden rays, and the nearer the former approaches black the better.

It can only be said that some of the more striking blooms in this glowing bed were among *Roses*—Mabel, above mentioned;

Modesty, a charming flower; Annie McGregor, equally beautiful in its deeper hue; Madame St. Arnaud, very bright; Mrs. Barlow, a grand breeder, also breaking into a perfect beauty; Apollo, tall and stately, with Lizzie Watkins, Hermione, and Mrs. Whittaker, all worthy of their rich surroundings. Of *Byblœmens* Storer's No. 2 heads the list with its magnificent blooms correctly marked, though the goblet is a little deeper than the coveted champagne glass form; then follows each with distinct properties of its own. Duchess of Sutherland, Friar Tuck, Mrs. Jackson, Mrs. Pickerill, Queen of May, Talisman, and a fine break from one of Hepworth's breeders. In *Bizarres* George Hayward stands out grandly with glorious blooms; Dr. Hardy attracted by its richness and bright clear pencillings; Sir Joseph Paxton, in different strains, was in splendid condition; Masterpiece, in brilliant colour, black and gold, but the disc not quite perfect; while Ajax, Hardwick's grand Bizarre, John Brook, Lord Lilford, and Pilot, with the dwarf Vivid and Colbert, shone brightly in the collection.

This beautiful Tulip bed affords the owner much pleasure, though he does not sit on an elevated throne at the end of the tent for days together watching the flowers as an old florist used to do in past times in Hertfordshire. Dr. Hogg—the name is out—has other things to divide his attention, namely a fine collection of hardy shrubs, including a grand seedling Horse Chestnut as well as a collection of young and beautiful fruit trees giving a great promise of fruit all round; but Tulips are just now in the ascendant and charm all who see them, as well they may, for it is doubtful if there is an equal display of grand blooms to be seen in the south of England.—PROBATIONER.

## POLLINATION OF TOMATO FLOWERS.

AMERICAN writers use the term pollination in the same sense as we do the word fertilisation in referring to the transference of pollen from the stamens to the stigma of the pistil connected with the seed vessel. In most cases this occurrence is absolutely necessary in the case of Tomatoes. Fourteen years ago I proved to my own satisfaction, and briefly stated in my first edition of "The Tomato," that more than ordinary pains ought always to be taken in fertilising the flowers if perfect formed fruit are desired. On page 49 I pointed out that the fruit is apt to swell unevenly unless the flowers are properly impregnated, and fully demonstrated what could be done in the way of improving the form of varieties not noted for their handsome appearance, by repeatedly showing Trophy in nearly as good condition as Perfection is frequently shown now-a-days. The flowers which preceded these fairly handsome fruit were selected, those with fasciated pistils being early pinched off, the pollen from one flower being transferred by contact with the pistil of another, two flowers being "pollinated" at one time. This may have been a rather rough and ready method of achieving the desired object—viz., perfect fertilisation, but it answered well, or better than merely tapping the flower stems when the pollen was dry enough to disperse, depending upon some of this to lodge on the stigmas.

I think now that not enough was made of this point, and it has been left to Mr. L. H. Bailey, Professor of Horticulture, Cornell University, Ithaca, New York, to more amply demonstrate how much may be done in a more effective manner than occurred to me to try. In connection with this University there is an agricultural experiment station, and the various experiments being constantly conducted and ably reported comprise much that is of interest to fruit growers generally. Tomatoes being extremely popular in America, they receive a rather large share of attention at the hands of Mr. Bailey and his assistants, this including house as well as open-air culture. The conclusion has been arrived at that during the short, dull days of winter "some artificial aid must be given the flowers to enable them to set," and also that the common practice of tapping the plants sharply several times during the middle of the day with a padded stick is not so effective as desirable. The practice is stated to be "better than nothing," but compares unfavourably with the plan of transferring the pollen by hand. I cannot do better than to let Mr. Bailey describe his and a friend's practices in his own words. "There are various methods of pollinating the flowers. The most expeditious and satisfactory method which I know is to knock the pollen from the flowers, catching it in a spoon, watch-glass, or other receptacle, and then dipping the stigmas of the same or other flowers into it. There is a time in the life of a flower when the pollen falls out readily

if the atmosphere is dry enough to hold dust; this is when the flower is fully expanded and somewhat past its prime. The flower is tapped lightly with a lead pencil, and the light yellow powder falls out freely."

Mr. C. J. Pennock, a Cornell graduate, considers pollination of the flowers, in the case of winter Tomatoes, very necessary, and goes over the whole of his plants daily while they are in flower. He has devised a tool for himself in the shape of a light piece of wood about 16 inches long and one-half inch square, at one end of which there is a saucer-like depression. This stick is held in the left hand with the depression under the flower to be pollinated, while another light stick is used for tapping the blossom to shake out the pollen, the end of the pistil or stigma being pressed at the same time into the pollen accumulated in the depression. Since he has adopted this simple and by no means a slow or tedious method of pollinating the flowers, a good set of fruit has always resulted, or much better than had hitherto been effected by using a brush or jarring the stems. In Mr. Bailey's report or "Bulletin" the effects of complete and faulty pollination are shown by means of illustrations of fruit whole and cut cleanly across, those most perfectly fertilised having all the cells furnished with seeds and properly developed, others not pollinated (I like this term best) or only partially so swelling very irregularly owing to some of the cells being seedless and solid. The experiments need not be described, but were exhaustive and conclusive.

A wide-spread dissemination of this serviceable information would perhaps have been more to the purpose in the autumn or winter months; but I hold that it is unwise to leave anything to chance even during the most favourable weather for pollinating Tomatoes. For ordinary purposes all that is necessary during the late spring and summer months, in the case of plants under glass, is to keep up a circulation of warm dry air, and when the pollen is quite dry, or say towards midday, to smartly jar the stems, tapping them with a padded stick in preference to anything that would bruise them. This disperses the pollen in clouds, and enough of it settles on the moist stigmas to effect a good set. When, however, the desire is to have extra fine yet perfectly formed fruit, then it pays to take a little more trouble in selecting the flowers and pollinating them. Any with fasciated pistils, notably the extra strong central flower on each strong bunch, should be early pinched off, removing this and thinning out the rest greatly strengthening or enlarging those reserved. Fine fruit never follow small flowers, nor will they be had if the pollination is not perfect.

In addition to the fruit most perfectly furnished with seeds attaining the largest size, I hold that they are also the best in point of quality, the pulp that surrounds seeds being of far better flavour than the core or solid matter in the cells where no seeds are formed. There is, therefore, much to be said in favour of trying either the one or the other of the American methods of pollination, and they certainly promise to surpass the older methods practised in this country during the autumn and winter months. It has been found that an abundance of pollen applied over the entire surface of the stigmas by increasing the number of seeds increases the size of the fruit, and once this fact is better known artificial pollination will also become more general.—W. IGGULDEN.

CYPRIPEDIUM GRANDE.

A GOOD specimen of this handsome Lady's Slipper is now in bloom in the Edgbaston Botanical Gardens, Birmingham. It was raised by Mr. Seden, at Messrs. Veitch & Sons' Nurseries, and is the largest of the Selenipedium hybrids, a cross between *C. longifolium* Hartwegi and *C. caudatum*, having the appearance of the latter. It is described in Mr. Veitch's Orchid book as having the staminode pale yellow fringed with blackish hairs at the back, the upper sepal yellowish white with yellow-green veins, the lower sepal similar but with paler veins; petals 12 to 15 or more inches long, rose pink, except the broader basilar portion which is

yellowish with green veins; lip greenish yellow toned with brown, paler beneath, the infolded lobes ivory white spotted with deep rose. The flower scapes frequently exceed a yard in length, and the flowers measure 7 to 8 inches across the sepals from the top. It has strong handsome foliage and is a very striking plant.—W. D.

#### LÆLIO-CATTLEYA ASCANIA.

ONE of the most beautiful Orchids shown at the Drill Hall on Tuesday, April 25th, was *Lælio-Cattleya Ascania*, a bloom of which is depicted in the accompanying illustration (fig. 65). It is a bigeneric hybrid, the result of a cross between *Lælia xanthina*

FIG. 65.—LÆLIO-CATTLEYA ASCANIA.

and *Cattleya Trianae*. The flowers are marked with the characteristics of both parents. The sepals and petals are pale sulphur yellow, the lip being of a richer shade, with a rich purplish crimson lobe. This interesting hybrid was exhibited by Messrs. J. Veitch & Sons, and a first-class certificate was awarded for it.

#### ODONTOGLOSSUM CRISPUM NOBILIUS.

THOSE who have not seen this splendid Orchid can scarcely form an adequate idea as to its beauty. There are many fine forms of *Odontoglossum crispum*, but in my opinion this is the best of them all. The flowers are very large, being quite 3 or 4 inches across when fully developed. The sepals and petals are white, heavily blotched with rich chestnut red. The labellum is also white, with a brownish red and yellow crest. I believe a first-class certificate was awarded for this grand variety last year.—C.

#### A MANUAL OF ORCHIDACEOUS PLANTS.

PART ix. of this admirable work has been issued by Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea, and, like its predecessors, it bears the stamp of careful preparation. The instalment before us comprises 194 pages, and the genera dealt with include *Cymbidium*, *Zygopetalum*, *Lycaste*, *Acineta*, *Stanhopea*, *Trichopilia*, *Cycnoches*, *Maxillaria*, *Mormodes*, and *Anguloas*. Detailed and accurate descriptions of the species and varieties of the above and other genera are given, and in many cases accompanied by admirably executed illustrations. We may again have occasion to refer to this excellent publication.

#### SALE OF ORCHIDS AT AYMESTREY COURT, WOOLTON.

ON Friday last the excellent collection of Orchids owned by Col. H. J. Robinson, and which have been so successfully cultivated by Mr. C. Osborne, were sold by auction by Mr. John Cowan. There was not a large number of persons present, consequently prices did not rule so high as might have been expected. The following were some of the higher prices realised:—*Cypripedium caudatum*, a fine specimen in a 9-inch pot, nine very strong growths and eleven flowers, 9 guineas; *Odontoglossum vexillarium*, twenty-one growths, thirty-five flower spikes, very fine

variety, £7 10s.; *Cypripedium Spicerianum*, 7 guineas; *Odontoglossum Alexandræ*, hybrid £5; *Cypripedium superbiens* (Prince Demidoff's variety), 7 guineas; *Cymbidium Lowianum*, £4; *Lælia purpurata alba*, £5; *Lælia anceps* (white), 4 guineas; *Odontoglossum Alexandræ*, A1 variety, £3 10s.; and *Sobralia macrantha alba*, £3 5s.—R. P. R.

### SUPERFLUOUS GROWTHS.

THE necessity of "thinning" crops has been repeatedly brought under the notice of readers of the *Journal*. As a phase of gardening, it is indeed one of the points which has been advocated for so long as I have read its pages, and that embraces a long series of years. To add anything further may therefore appear superfluous; but, as there are always new readers, an old tale is fresh, and, moreover, I hope to show that the last word has not yet been said on the subject under review. I shall pass over the thinning of Vine growths, not because I do not realise its necessity, as I am persuaded the well-being of Grape Vines depends very much on the foliage being fully exposed alike to air and light; and in the same connection other kinds of fruits which are sometimes seen too thickly leaved through neglect in thinning out spurs and branches are not referred to at present. The particular "crop" I wish to draw attention to is the large one of plants grown in pots.

I do not think I exaggerate in saying that no young man of his own initiative ever attempts to thin out the shoots or foliage of pot plants. That, at least, is my experience. On the other hand, most young men have a good idea as to the need of thinning in the case of fruit trees. Tell an assistant to thin the shoots of a Vine or a Peach tree, and in most cases he knows how to set about it; but set him to thin a *Pelargonium*, and invariably he has to be told what to do. The obvious reason is that in the former case thinning is a matter of routine; while in the latter it does not appear to obtain to any great extent.

At first sight it appears somewhat peculiar that the removal of a few weakly growths and leaves from a plant in good health should exert so palpable an influence on the future of that plant. The immediate result is an increased vigour in the foliage and growth of the plant, and ultimately more bloom of better quality. One would naturally think that so long as growth is not, I will not say overcrowded, but simply not close, there would be benefit to the plant from the greater amount of foliage; but in practice it is not so. Every weakly growth, whether it crowds a stronger one or not, is a task on the energies of the plant, and there is an immediate improvement in the general development of the other shoots directly these are removed. There is something more than merely an increase of light and of air to be reckoned with, for in many cases which have come under my notice there were absolutely nothing like crowding of shoots or of foliage; yet the removal of weakly shoots, and sometimes of small leaves alone, had a pronounced effect on the plant. It would appear that a concentration of the energies of the plant on the best placed shoots possessed an equality of vigour, the chief factor in achieving this result.

I confess that when I at first began to thin plants in this way it was not with any idea of improving them, or of gaining an increase in vigour. I merely saw no good in leaving shoots which in no case could be expected to flower, but the result, as already said, is a marked improvement in all kinds of plants. As examples of what I mean, we take for example a *Tuberous Begonia*, which at present is producing a score of young growths from its crown. There is space for only a fraction of these growths; it may be one-half, perhaps a quarter. The result, if all are left, is that a few take the lead, and possibly no harm may be apparent from allowing all to remain; but if all the weaker growths are removed the vigour of those left will be enhanced in a remarkable degree. And suppose, as is sure to be the case, that young side shoots are developed as the first crop of flowers begins to go off, by the simple method of removing all growths which have done flowering the plant will become as vigorous and as floriferous as ever. I have treated plants of *Begonia Gloire de Sceaux* twice during the past winter to this cutting-out process, and they are still in beauty.

Again, let us take a very common plant—the *Fuchsia*, and instead of letting every weakly growth remain, and pinch-in every strong one to increase the strength of those which by no possibility can be strengthened, let us adopt the drastic method of removing every weakly shoot, and we secure vigour at once. Perhaps the most remarkable effect is exhibited by *Carnations*. The strongest, most floriferous, and largest-flowered flower stem is produced when the "grass" or the young shoots are thinned out. These, apparently,

can have no effect on a stem towering above them; but it is a fact that removing a thick growth of young shoots round the base of the plant has a great effect for the better. Bush *Chrysanthemums* furnish another example. Though there may to all appearance be plenty of room for the development of strong and weakly shoots, it will be always found better to remove the latter at an early period of their growth. The difference is made up by those left producing a larger number of flowers, and all of a better quality. I might add examples, but merely notice *Crotons*, which are improved by the removal of growths in the case of the small foliage sorts; while in those with large leaves all small ones taken off help others yet to come.—B.

### HARDY FLOWER NOTES.

It is well nigh impossible to write of the flowers of April without, to some extent at least, referring to the glorious weather we have had while the month of smiles and tears has been with us. She has falsified her proverbial reputation for once, and the bright sun and clear air have harmonised well with the beauty of the flowers which responded to the wooing of the sun and genial air. The season has, indeed, been a veritable "bridal of the earth and sky," as George Herbert says, and those who admire the flowers of spring have enjoyed a rich banquet of beauty. It is delightful to gaze on the garden's beauty, glowing as it is with golden *Alyssum*, with gleaming *Tulips* glancing in the sunlight; alpine *Phloxes* covering the stones of the rock garden with mossy carpets covered with flowers of varied tint; spikes of *Honesty*, varying through shades of purple or of snowy whiteness; stately *Crown Imperials*, *Chapman's Emperor of Flowers*, starry *Saxifrages*, drooping *Lyre Flowers*, or *Bleeding Hearts*, as *Dielytra spectabilis* is called; *Welsh Poppies*, *Lungworts*; *Primulas*, from the ever-popular *Primrose* of the hedgerow to the rarer species from other lands; *Arabis*, *Aubrietias*, and the many other flowers which gladden our eyes and by their number bewilder our thoughts.

Few of these have been finer than the varieties of *Primula Sieboldi*, a number of which from seed from one of the best strains in cultivation are brightening (if brightening were needed) a range of rockwork of some length. Here they are planted at the base, where they receive the benefit of the overflow from the terraces above, and where they are flourishing in great beauty. Very attractive are they with their flowers of varied form or colour, some being nearly round and others deeply cut and fringed, while the colouring is still more varied, some being pure white, others white with the backs of the petals rose, and others again ranging from pink to deep purple. Planted in sandy peat they are increasing rapidly, and although various pieces have been given to other flower lovers nearly all have filled their allotted space. They are so hardy and so beautiful that no one need hesitate to include these beautiful flowers in their collections. It is well, however, to remember that they die so completely down that they are difficult to perceive when at rest, and are thus at times destroyed by careless digging.

Very beautiful, too, have been the various *Anemones* which are so numerous both in species and variety that a lengthened notice would be required to do them justice. Our ordinary Wood *Anemone A. nemorosa*, when seen in masses in our woods is most attractive, and near me many beautiful examples of its decorative effect may be seen. It is not our purpose, however, to speak at length of the ordinary form, but to call attention to some of the varieties of this flower which, as Lord Lytton says, is

"fashioned so  
Like to the stars of the winter snow."

One of the most recommendable varieties and one of the best known is *A. nemorosa fl.-pl.*, the double form, which is very pretty with its button-like blossoms, not so unlike the flowers of the "Fair Maids of France," but if anything of still purer whiteness. Always interesting, too, although not so readily appreciated by the ordinary frequenter of gardens is *A. n. bracteata*, "the Jack in the Green" of *Anemones*, with its leafy bracts and its neat flowers. Then we have the rosy coloured varieties and several others with flowers larger than the ordinary kind. Doubly welcome, however, although not perhaps so much appreciated since *A. apennina* became more widely grown, and since *A. blanda* made its appearance in our gardens, are the varieties of *A. nemorosa* with bluish or blue flowers. Perhaps the one of these most frequently seen (if frequently can be used where a flower is only seldom seen) is *A. n. cœrulea*, with pale blue flowers. A rare variety which, through the kindness of the finder, I have flowered this year has been named *A. n. purpurea*. This was discovered in France some years ago, and is quite distinct in colour from the ordinary bluish

varieties. I do not, however, believe that any of these will ever surpass in the estimation of the lover of the Anemone species that beautiful plant *A. n. coerulescens*, which has no rival in respect of colour, and few competitors as regards size. This year it has been particularly fine with me in an eastern aspect at the base of a rockery. A plant so planted has been very attractive, with its pleasing blue flowers of large size, one I measured the other day being no less than  $2\frac{1}{8}$  inch across.

I have at various times expressed my regret at the loss of, or difficulty of, obtaining flowers which were well known long ago, and in the case of the Wood Anemones we seem to have lost two or three varieties, and here my authority for their former existence is Philip Miller, the pages of whose "Gardener's Dictionary" may with profit be frequently searched. In the edition of 1735, under the heading of "*Anemonoides*; Wood Anemone; vulgo.;" among others he speaks of a "Wood Anemone with double purple flowers;" a "Wood Anemone with large double blue flowers;" and a "Wood Anemone with purplish-red flowers." The first and the last may possibly be our rosy coloured forms, which are not otherwise mentioned by Miller, but the one with large double blue flowers I have been unable to hear anything of, unless a plant which is grown as the double form of *A. apennina*, but which I have not seen, may be the one of which Miller speaks. This is hardly probable, and the following extract from the "Gardener's Dictionary" may be of interest, and may also lead to the discovery of this plant. "The other varieties" (i.e., other than the single white) "I have gathered in great plenty in the wildernesses belonging to the gardens at Wimbleton (*sic*) in Surrey, which were, probably, at first taken from some woods in England; in this place they increase so fast that the surface of the ground is covered with them in the spring; and, what is more remarkable, that there the large blue and double sorts are the most common." Closely allied to *A. nemorosa* is *A. trifolia* with pretty white flowers with white sepals, and having ternate leaves. This was introduced from France in 1597. This year I had the pleasure of receiving a pretty variety—a seedling from *A. trifolia*—with white flowers, having a bright pink or rose-coloured zone-like centre. This was raised at Shepton Mallet by Mr. James Allen, and may be the beginning of a new departure in this species.

Many other Anemones would call for notice, conspicuous among them being the St. Brigid varieties of *A. coronaria*, recently noticed in the Journal. These I have grown for several years, and no encomiums can exaggerate their beauty or merit. Leaving for the present other species, I am led to notice more on account of its comparative rarity than for its beauty, a little-known species known as *A. albana*, described in Paxton's "Botanical Dictionary," and the older edition of the "Cottage Gardener's Dictionary" as white, but which would be more correctly called pale sulphur. With me it grows to about 9 inches in height, 3 inches more than the height given by these authorities, and although not of the first order of merit, is desirable with its rather hairy fresh green leaves, and its somewhat bell-shaped flowers, the sepals of which are covered on the outside with silky hairs. *A. albana* is a native of the Caucasus, whence it was introduced in 1821. It appears to grow well in ordinary loam, and is suitable for the front row of the border, although grown here on the rockery where its flowers are seen to more advantage. The press of other flowers will for the present prevent further reference to one of the most attractive genera in our gardens.

The brilliant display afforded by the golden Rock Madwort (*Alyssum saxatile*) is so much appreciated that its claims to further notice need not be dilated upon. Worthy, however, of attention from its neater and dwarfer habit is the variety of *A. saxatile compactum* which, like so many other dwarf flowers, rejoices under the title of "Tom Thumb." This variety was sent out by, I believe, Messrs. Backhouse some five or six years ago, and is now finding its way into the trade generally. For many purposes it will be found superior to the typical *A. saxatile* or to *A. s. compactum*, as it only grows to a height of 6 to 9 inches and flowers as profusely as the others. It will hardly come true from seed, but it is easily increased by means of cuttings inserted after the period of flowering in sandy soil and covered with a handlight or bellglass which should be shaded.

The first of the Poppyworts of the season, although not long preceding *Papaver nudicaule*, has been *Meconopsis cambrica*, which is always welcome with its clear yellow flowers and its fresh finely divided foliage. This little "Welsh Poppy," as it is popularly called, is so accommodating in its habits that it has become widely spread among gardens here. In my own garden it flowers in the sun and in the shade, and sows itself with great freedom.

But, alas! one must close, and with a regretful look at flowers of the highest order of beauty which I have either spoken of before or for which the exigencies of space will not afford

opportunity we must close and turn to the garden, with its stores of beauty such as no pen can describe and so fitted as to entrance us with their loveliness.—S. ARNOTT.

## GRAPES—SELECTING AND THINNING THE BUNCHES.

A BUSY time is now at hand for Grape growers. Thanks in a great measure to the long spell of sunshine Muscats have set splendidly, so the question as to how many bunches each individual Vine is capable of ripening satisfactorily should be determined forthwith. Needless to say, the finest, best placed, and most evenly set bunches should be retained, these being distributed regularly along the Vines. The vigour and length of each Vine should be considered in deciding the number of bunches that shall form the crop as well as the size of the bunches which the cultivator has the choice of retaining or removing. A fully established and well-conditioned Vine, say 19 feet in length, of Black Hamburgh, Muscat of Alexandria, Gros Maroc, Gros Colman, Mrs. Pince's Black Muscat, Foster's Seedling, Mrs. Pearson, Black Alicante, Buckland Sweetwater, and Madresfield Court, showing fairly large framed bunches, bunches likely to turn the scale at 3 lbs. when ripe, and colour well at the same time, should not be allowed to carry more than seven such bunches for a crop. A greater or lesser number of bunches, according to their size and the length of the Vine, may be safely retained for a crop, providing the weight of Grapes does not much exceed 1 lb. per foot in length of the Vine.

In the case of "large-bunch" varieties, such as Gros Guillaume and Trebbiano, mistakes are often made in leaving more bunches for a crop than the Vine can possibly "finish" satisfactorily, cultivators forgetting at the right time that the larger the bunches promise to be the fewer they should be in number for the crop. Three or four 7-lb. bunches of Trebbiano are ample for one Vine if its permanent vigour is considered, as it should be. One 12-lb. bunch of Gros Guillaume and one or two smaller bunches should be allowed for a crop in preference to leaving two large bunches. In a general way, ten or eleven bunches of Lady Downe's, weighing from  $1\frac{1}{2}$  lb. to  $2\frac{1}{2}$  lbs. each, may be left on each Vine of the length indicated for a crop. Superfluous bunches should be removed as soon as the best bunches can safely be determined, and the berries ought to be thinned on those retained for the crop as early as possible after they have set, so as to not unnecessarily waste the forces of the Vines, as is the case when the Grapes are allowed to become as large as Green Peas before being thinned.

The berries should be thinned out to 1 inch from berry to berry as soon as possible after they are set, retaining the crown or central berries, and being careful not to rub the bunches in any way, or to injure the berries with the scissors. In addition to a sharp-pointed pair of scissors, those engaged in the work of thinning should have a small forked birch twig for raising the shoulders of the bunches in the process of thinning. Loose shoulders are best cut off, as single-stemmed bunches are preferable. Large bunches of Gros Guillaume and Trebbiano should have the shoulders tied neatly and carefully out, suspending the points with a series of ties from the trellis, care being taken to give additional support to the points and shoulders generally as they extend in growth, otherwise the increased weight of the extremities of the bunch will cause them to assume a perpendicular position, and to cut at the point of contact with the trees.

With regard to Gros Maroc and Gros Colman, a space of rather more than 1 inch from berry to berry should be allowed in thinning; and in thinning bunches of Buckland Sweetwater and Gros Guillaume, all that is necessary in a general way is to cut out all the small berries, as these, being furnished with long footstalks, will have ample room to swell out to proper dimensions. In conclusion, I may remark that the Vines should be kept well supplied with water at the roots during the next four or five months, giving surface dressings of Thomson's Vine manure or some other approved artificial before applying clear water, and copious waterings of liquid manure, not too strong, being given at the roots alternately with the applications of clear water, and results of the most satisfactory kind may be looked for, other points being duly attended to during the period mentioned.—H. W. WARD, *Longford Castle*.

## NATIONAL AURICULA SOCIETY.

### SOUTHERN SECTION EXHIBITION.

I HAVE for a number of years—in fact, ever since the Society was established—given my estimate of the character of its exhibitions; these have been of the most varied description, and I have sometimes been severely criticised because I have written dis-

paragingly of the exhibits, and at other times I have been told that my faint praise was worse than downright censure. I have pleaded in extenuation that I was brought up in a very rigid school of florists, and that I could not bear patiently the more lax views entertained of recent years. By those old world ideas I still hold, and my notes of the Exhibition of last Tuesday must be guided by them, as they have been in former years.

I, however, think that there will not be anyone, either of the older or modern school of florists, who will be prepared to deny that the exhibition on Tuesday last was an inferior one, and was another instance of the old saying "Never prophesy till you are sure." Very glowing anticipations were indulged in, if I remember rightly, in the pages of the *Journal* as to the splendid prospects of the Show, and perhaps in many quarters these were well founded; but it was not strange that in this absolutely unique season they should have been all falsified by the enchanting weather of March and April, and while many would have hailed a date a week earlier than usual it so happened that the Show was nearly a week later, and these two factors led to the result which I have already mentioned, and this, if noticeable amongst the Auriculas, was still more so amongst the Primulas. A friend of mine came up all the way from Torquay on purpose to see these, and of course was grievously disappointed; true, he had plenty of other things to look at, but for the one special object of his journey there was, comparatively speaking, little to compensate him for his trouble. Another proof of the earliness of the season was the appearance in several cases of fine trusses of that latest of all Auriculas Richard Headly, which is certainly one of the best grey edges in cultivation, its rich gold-coloured eye giving it a bright and lovely appearance. It well commemorates the raiser and the grower, after which it is named, as does George Lightbody, raised by Mr. Headly.

As the list of prizewinners has already been given, I shall in my notes dispense with repeating them, and refer only to special points. Of course, we naturally look for the best flowers in those staged by that "past master" in Auricula growing, the Rev. F. D. Horner, and in his stands are pretty sure to find some of the best flowers in the Show. Nor was this year an exception. The premier plant was to be found here, and one which also obtained Mr. Smith's special prize for the best green-edge, to be superior to any of those already in cultivation. The flower which gained this distinction was a seedling of Mr. Ben Simonite's, bearing the honoured name of Shirley Hibberd—had it been in France it would have been called "Souvenir de Shirley Hibberd." It a beautiful flower with a brilliant green edge, and is apparently of the same series as Ben's other fine flower, the Rev. F. D. Horner, but the paste seemed to me to be better, and therefore the body colour was not so apt to come through as it does sometimes in that fine flower; the green-edge is a scarce class. Col. Taylor, a very old flower, has several failings. Prince of Greens has a brilliant edge, but a pale watery eye, and Imperator is rarely seen in good exhibition form. Booth's Freedom has almost gone out of cultivation. We may perhaps include in this class Lancashire Hero, which sometimes as a green edge is the most beautiful of all, but then it is not truly a green-edged flower; there is nothing else to compare with these two flowers of Ben Simonite's, the Rev. F. D. Horner and Shirley Hibberd. There was also in this stand a fine bloom of Alexander Meiklejohn; in fact, the finest I have seen for some years, as also Magpie, which I have already in former years written of as the best flower Mr. Horner has raised, and probably the best white edge in cultivation. Mr. Horner had also a very fine seedling called "Dusk," which promises to be useful in its class. There were few examples of that finest of all Auriculas Geo. Lightbody, although one or two excellent blooms of it were shown.

I was very much pleased to see the position which the flowers raised by my late lamented friend Mr. Woodhead, whose early death was so great a loss. He only raised, or rather sent out, four flowers—Black Bess, Rachel, Geo. Rudd, and Mrs. Dodwell; yet these were to be found everywhere in the winning stands, and in two notable cases occupied a very favourable place in the class for single selfs. The first of these (Black Bess) carried off the first and second prizes, beating that very much cracked-up flower, Mrs. Potts, which, though beautiful and almost perfect in its flower, is so hopelessly ungainly in its growth as to deprive it of most of its value. It out-tops all other plants, and moreover the footstalks are so long that the blooms sprawl about. By-the-by, that fine flower Heroine was completely out of court. It is an early flower, and I do not recollect seeing a plant of it in the Exhibition. Again, in the class for two plants the first prize was taken by two of Mr. Woodhead's flowers, Rachel and Mrs. Dodwell, a grey and a white edge. I am sure these facts must be most gratifying to Miss Woodhead, while to myself it is also pleasant to find that the estimate I had formed of these flowers was a correct one; and one cannot cease to regret that a grower who had

so evidently hit upon the right plan for hybridising had been so prematurely taken from amongst us. In this connection recurs to me an observation made by one of our best growers, who pathetically said to me at the Drill Hall, "Ah, my dear D., who is to succeed us?" Well, the prospect is perhaps somewhat gloomy, but there are some who will take up the running, although I fear that those who will occupy the place of the speaker are not in evidence. The Auricula is not popular, like the Rose, the Chrysanthemum, or the Carnation. It is the flower of the few, not of the many; the estimate of it even amongst gardeners is just what I overheard the other day. Three persons, who seemed to me to be gentlemen's gardeners, were standing opposite a collection of Calceolarias, very beautiful, but very common things, when one addresses his fellows, "See those men over there," pointing to a group of florists who were discussing the merits of some Auriculas, "why they will stand there all day discussing those things, and yet will not give a look at these beautiful plants." *O tempora!* &c., to compare the Auricula with a Calcy, or listen to the ladies. A few of them will call them loves, &c., but the general idea is expressed by "Oh! I don't think much of them; they are so stiff and formal, and then you know you can't cut them, and they are no good for bouquets."

Yet withal there has always been a select few to whom the Auricula is very precious, and I confess to being one of them. They are associated with my earliest days of horticulture; they have formed a bond of union with many a brother florist, and they give a zest to meetings such as those on Tuesday, when we see friends we are not likely to see at any other time, and find topics of conversation in the flowers we love so much.

Such are a few of the things which strike me in connection with this Show. It has not been a good Auricula year. Many plants did not bloom at all. Many threw small trusses; and I was glad to see that this did not condemn a plant; nor did a truss of twelve or thirteen, half of which had better been away, commend a plant. And so another season has passed. The younger growers will look hopefully on; the older ones, like myself, will ask themselves with sobered thoughts, Shall I ever see another? But we must do our best to encourage others, and tell them what a fund of enjoyment there is in the cultivation of this refined and beautiful flower.—D., Deal.

#### DRY WEATHER.

I HAVE a distinct recollection of the hot and dry weather experienced during the summer of 1868, not perhaps so much from my horticultural remembrance of it, although in some respects this was the case. I cannot say that I recorded the number of rainless days, but I know they were many. During June of that year I was suffering from illness, which interfered with my annual visit to the grand Yorkshire Gala held that month in my native city.

"An Old Gardener" (page 329) may be surprised to learn that I, so early as that year, did make a few Chrysanthemum cuttings. The method of growing the plants differed much in those days to the present fashion, and so did the varieties. On reference to my diary of that year I find noted such sorts as Queen of England, Venus, and Aigle d'Or. It was deemed necessary then to employ as many stakes as the plants had blooms, numbering hundreds to each.

Referring to our rain table of the present year, from February 1st to April 21st, as requested on page 329, I find recorded 3.84 inches, 0.35 inch, and 0.04 inch, or a total of 4.23 inches for the three months. This is considerably in excess of the total recorded by "An Old Gardener," February keeping up to its reputation of "Fill dyke." During the quoted period rain fell on twenty-four days, none whatever falling on fifty-one of that period. It will thus be seen that the rain during two of the months quoted—March and April—is less than one-third of the quantity which fell in 1868, and really for horticultural purposes the total rainfall for the three months of this year is of less benefit than that quoted by your correspondent; 3 inches of rain, falling at intervals of an inch at a time, is of more benefit to growing crops than the same quantity falling at once. With the exception of 0.04 inch, recorded for April 16th, and 0.02 inch on the 29th, we have up to the present time (May 1st) had sixty-five rainless days from February 1st, and at present the prospect is a continuance of the same order. Looking over the records taken during the last ten years, I find 1892 credited with the greatest number of dry days—253. The year 1889 follows next, with but six less. Singular to relate, the years 1883 and 1884 record the same number of days upon which rain (0.01 inch) fell—135, giving a total for each year of 230 dry days.

The total rainfall here for the last ten years is 300.60 inches, the average being 30.06 inches, which is a fairly good one considering the altitude, 390 feet above sea level. In spite of the unusual drought so early in the year the crops and trees look remarkably well in the strong land of this neighbourhood, except Grass and Clover. Trifolium is now in flower, and but a few inches high. Even the Brassica tribe have not yet taken on that blue tint of the leaf which betokens a suffering from want of moisture at the roots. It is the newly sown and planted crops that need attention in the matter of watering, mulching, and surface stirring. I can manage without complaint all garden crops, but

it is the 50,000 Larch, and a quarter of that number of evergreen Firs planted last season, that I despair of if a change does not quickly come.

Regarding the blossoming of Hawthorns in April it is indeed a rare occurrence here even. I have on several occasions known these trees not to be in bloom in May, but at present the likelihood of the blossoms falling from the trees before May has been in but a short time is not remote. Another instance of the precocious nature of this season is the fact of the leaves on the Oak trees are at the present time fully developed, whereas in some seasons on May 29th I have experienced a difficulty in finding leaves so forward.—E. MOLYNEUX, *Swanmore Park, Hants.*

**EVENTS OF THE WEEK.**—Next week will be a busy one amongst horticulturists in the metropolis. On Tuesday, May 9th, the Committees of the Royal Horticultural Society will meet at the Drill Hall, particulars of which are given in another paragraph. The Horticultural Club and National Rose Society meet at the Hotel Windsor, Victoria Street, on the same day. A flower show will take place at the Crystal Palace on Thursday and Friday the 11th and 12th inst., and on Saturday, May 13th, the Gardening and Forestry Exhibition at Earl's Court will be opened.

**THE WEATHER IN LONDON.**—With the exception of a few slight showers, the weather during the past week has again been remarkably dry. The rain fell in the metropolis on Monday and Tuesday night, but scarcely sufficient to moisten the soil. At the time of going to press it is cloudy at times with a little prospect of the much-needed rain.

**WEATHER IN THE NORTH.**—Although the weather of last week has been on the whole good for the season, very cold north-westerly winds prevailed during the latter part, particularly on Saturday and Sunday. Some showers fell on these days, but owing to the wind they had little effect. Slight frost occurred during the morning of the 1st inst., with heavy showers at intervals during the day. This morning (May 2nd) is calm and dull with light drizzling rain and promise of more.—B. D., *S. Perthshire.*

**THE GARDENING AND FORESTRY EXHIBITION.**—A private view was accorded to several gentlemen to this Exhibition and its popular adjuncts—the French Bastille and Captain Boyton's Water Show, on Tuesday. A great deal remains to be done in all departments, but the work will no doubt be completed by the opening day, May 13th. The combined attractions will be of a remarkable character, and a fuller account of the great undertaking will be given next week.

**ROYAL HORTICULTURAL SOCIETY.**—The next display of flowers, fruits, &c., will take place on Tuesday, May 9th, at the Drill Hall, James Street, Victoria Street, Westminster. Professor Cheshire will lecture on "How to Solve Chemical Questions Concerning the Soil," at 3 P.M. The Temple Show on May 25th and 26th will intervene between this and the next Drill Hall meeting, June 6th.

**OXFORD BOTANIC GARDENS.**—It is stated that these gardens are to be improved by the renewal and extension of the glass houses, the University having voted £3500 for the purpose, the expenditure to be spread over three years. The Gardens are held of Magdalen College, on a lease of sixty years, and when this was granted in 1876, it was stipulated that repairs estimated to amount to £5580 should be carried out, but only £2200 of this has been laid out as yet.

**EARLY STRAWBERRIES.**—Mr. W. N. White, fruit broker, Covent Garden, writes to the *Times* as follows:—"It may be of interest to many of your readers, comparing one season with another, to hear that we have to-day (May 2nd) received from the growers of Saltash, Cornwall, our first consignments of Strawberries grown in the open, being the earliest on record. The first consignment last year only reached this market on June 4th, and some years we have known it to be the 10th and 12th of June before they came forward. We consider the season to be five weeks earlier than ordinary. We also yesterday received the first large supply of French Cherries in flats, which we notice did not come forward last year until May 16th."

**THE EARLY SEASON.**—Mr. John Carter writes from Keighley, Yorkshire:—"For more than sixty years I have specially noticed Purple Beech showing its first leaves not earlier than 7th May, this year we had leaves on Friday, 21st April."

**SELLING FRUIT BY WEIGHT.**—It is stated that the Market Committee of the Town Council of Edinburgh, in reporting upon a letter from the Secretary of the Edinburgh Market Gardeners' Association, recommend that in future small or soft fruit should be sold by weight only.

**FRENCH BEAN, SUTTON'S FORCING.**—I have tested many varieties of French Beans for forcing, but I find none equal to this. In growth it resembles Osborn's, but is rather taller. Its cropping quality is superior to that old favourite, producing more pods, which are of superior quality.—E. MOLYNEUX.

**JOHNSON'S GARDENERS' DICTIONARY.**—Part III. of the new edition of this dictionary embraces the description of plants from the genus *Corylopsis* to Ferns. Cultural details relative to stove, greenhouse, and hardy Ferns are given, and their methods of propagation described. As before stated the work will be completed in eight parts.

**BIRMINGHAM AND DISTRICT AMATEUR GARDENERS.**—Mr. F. T. Poulson of Stafford recently gave an instructive paper on "Auriculas as Town Plants" before the members of the above Association. He advocated the encouragement of the growth of these plants by town dwellers. Fresh soil, clean pots, and plenty of drainage were all that was required to ensure good plants. A vote of thanks was passed to Mr. Poulson for his paper.

**ROYAL BOTANIC SOCIETY.**—Mr. J. Douglas writes:—"There are two errors in the report of this Exhibition on page 343. I received the small silver medal for Primulas and Auriculas, the bronze medal being awarded to Mr. Chas. Turner. Mr. Turner could not have shown the self Auricula Engineer, as there is but one plant in existence, and that belonged to Mr. A. J. Sanders, who obtained for it a floral certificate."

**THE TOTAL RAINFALL AT ABBOTS LEIGH, SUSSEX,** for the past month was 0.5 inch, which fell on the morning of the 17th. This makes the rainfall for the four months 3.15 inches below the average. The highest temperature was 80° on 20th. Highest in the sun 101° on 21st and 25th. Mean maximum, 64.19°; mean minimum, 39.08°; mean temperature, 51.13°—6.09° above the average. Hot sun and drying winds have dried the land to a remarkable extent, and rain is now very much wanted for growing crops.—R. I.

**DEATH OF MR. EDWARD SANDERSON.**—We regret to have to announce the death of Mr. Edward Sanderson of Chrysanthemum fame, which sad event occurred on Thursday last. The deceased gentleman had been unwell for some time, but his end was sudden and unexpected. Mr. Sanderson was officially connected with the Stoke Newington Chrysanthemum Society, which developed into the National Chrysanthemum Society, for thirty years, and for a long time occupied the position of President. He was a skilful grower of incurved blooms, and few men have staged smarter examples than he did. Mr. Sanderson was a most happy and genial man, highly respected by a wide circle of friends. His remains were interred at Willesden on Tuesday last, several of the officials and members of the N.C.S. being present at the ceremony, and placed a beautiful wreath on the coffin, which was covered with flowers from a number of friends. Mr. Sanderson was seventy-five years of age.

**HALLAMSHIRE FLORAL AND HORTICULTURAL SOCIETY PRESENTATION.**—At the last annual meeting of this Society Mr. Joseph Hancock, the Secretary, tendered his resignation in consequence of his entering a new sphere of labour, which would necessitate the severing of his connection with the Society. He had held the position for seventeen years, commencing when the Society was in somewhat low water and possessing but few members. By dint of perseverance and hard work his efforts were rewarded, and now the Society is in a prosperous condition. This is, for the most part, due to Mr. Hancock's untiring efforts, and the members thought that they could not allow him to leave them without some memento from them of their appreciation of his labours. A subscription list was, therefore, opened amongst the members, with Mr. Hamer Chalmer as Treasurer, and a goodly sum was raised. A handsome writing table of walnut, containing nine drawers, was purchased, and on the plate a suitable inscription was placed. The balance, 10 guineas, made up a purse.

— CARNATION PRIDE OF GREAT BRITAIN.—Mr. T. S. Ware sends us from Tottenham a bloom of this yellow Carnation, which he describes as unquestionably the best yellow Carnation ever raised. It is a border variety, and a very robust grower. The bloom is one of the largest we have seen, equalling in that respect *Souvenir de la Malmaison*, and pure, soft, yet bright yellow in colour.

— APPLE BUDS AND SPARROWS.—It is nothing fresh to me to hear of these pests stripping "W. R. Raillem's" (page 341) trees of the bloom buds. I look upon the sparrows as far more destructive in the fruit garden than the bullfinch; they favour the bloom buds of Pear trees more than the Apples. Nothing but a persistent war both winter and summer will lessen the damage annually done by this bird. In the same way I persistently kill all squirrels that enter the garden, or the woods for the matter of that.—E. M.

— BEDDING IN BATTERSEA PARK. — The bedding which is always such a noticeable feature in this charming park, has this year been started at an unusually early date. Already *Lobelias*, *Zonal Pelargoniums*, and *Gazanias* are being planted, and it is to be hoped that no frosts will now come, which will have a bad effect on them. However, I learn that Mr. Coppin, the Superintendent, is very wisely keeping plants in reserve, so that he is quite prepared to replace what may be killed or seriously injured.—H. J. W.

— CYCAS REVOLUTA FLOWERING.—Mr. A. Parrott of Cymlyn Burrows, Swansea, writes:—"I have a female plant of *Cycas revoluta* flowering here, which thirteen years ago had only five leaves, which I think rather unusual in one so young. Will any of your correspondents kindly give their experience if that is the case? And if anyone who has a male plant in flower will send cone, if seed result I will equally divide the same." [*Cycas* is dioecious, that is, the male and female organs are on different plants; so that "suckers or side shoots" from a female plant will not produce male plants.]

— CHISLEHURST AND DISTRICT GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—The above Society brought to a close a most successful winter session by an annual dinner on the 26th ult., when between sixty and seventy members and friends were present. The President, Mr. Lyne, gardener at Foxbury, along with the Hon. Sec. and other officers, have reason to be pleased with the present condition of the Society. During the past session many interesting papers were read. A circulating library of books of horticultural interest has been instituted in connection with the Society.

— THE DROUGHT AND FIRE ENGINES.—The urgent need for water in many country districts for the purposes of irrigating the land has led Mr. J. C. Merryweather, head of the well-known firm of fire-engine manufacturers, to send us particulars respecting the use of fire engines for watering crops and shrubs. We know how adapted a fire engine is for pumping water through long lines of light, portable, and flexible hose piping, by means of which, with suitable nozzles, either a heavy shower or a fine spray can be used on any part of an estate in a very short space of time. Messrs. Merryweather inform us that they are ready to advise farmers and landowners on the subject, and will undertake to lend the necessary machines at a few hours' notice. Many estates now maintain excellent fire engines both of the "Brigade" and "Squire's" pattern, and these might also be brought into service for irrigating purposes. We have seen them so used with excellent results.

— DRY WEATHER IN FRANCE.—It would seem that the spell of dry weather has been experienced on the Continent as well as in some parts of this country. A daily contemporary observes:—"The long-continued dry weather, which has now lasted in France for about seven weeks, is beginning to cause grave anxiety among agriculturists. Cereal crops are almost everywhere suffering greatly. The Clover and Lucerne crops are seriously endangered all over the country. Wheat, especially in the Beauce district, which is known as the granary of Paris, is generally withering and dying. In the north the drought threatens to be equally detrimental to the Beetroot crop. Beet sown after the beginning of the previous month is in a bad condition, as there has not been the moisture in the soil which is necessary for the proper development of the seed. Vines, on the other hand, which have so far given excellent promise, have not yet experienced any ill effect from the dry weather, and have only received a slight check from a few very cold nights recently, especially in Lower Burgundy, Aude, and the Orléannais. In the Beaujolais and Bordelais districts, and in Champagne, however, the appearance of the vineyards is splendid."

— LILACS IN BATTERSEA PARK.—It is now many years since I have seen the Lilacs in Battersea Park so fine as they have been this season. The quantities of bloom have been extraordinary. Unfortunately, owing to the hot dry weather, the flowers have very rapidly faded, and much of their beauty has, in a measure, been lost to the surrounding inhabitants, who so highly appreciate this delightful resort.—E. H. W.

— BOTANIST TO THE U.S. DEPARTMENT OF AGRICULTURE.—We learn from the "Garden and Forest" that Mr. Frederick Vernon Coville, one of the staff of the botanical section of the Department of Agriculture of the United States, and recently associated with Mr. E. Hart Merriam's Death Valley Expedition, has been appointed chief of the botanical division of the department, in place of the late Dr. George Vasey.

— PAMPAS GRASS PLUMES.—In the April number of the "Overland Monthly" it is stated that Pampas Grass was first introduced into the United States in 1848 from South America, where the area covered by this Grass amounts to 1,500,000 square miles. The plumes have been grown for market in California only since 1872. From one tract of 28 acres in that State, 260,000 plumes were sold in 1890. In California the Grass grows to a height of 20 feet, and a single stool attains an equal diameter. The principal market for the plumes is in London and Hamburg.

— THE HORTUS LODGE OF FREEMASONS.—Recently a considerable number of horticultural members of the Masonic fraternity from various parts of the country assembled at Freemasons' Hall, Great Queen Street, W.C., to take part in the consecration of the Hortus Lodge, for the establishment of which H.R.H. the Prince of Wales, M.W. Grand Master, has been pleased to grant a Warrant of Constitution to a small but influential body of metropolitan horticulturists. We understand that membership of the new lodge is to be restricted as closely as possible to members of the horticultural community.

— A "KEWITES" DINNER.—We are informed that the Kew gardeners gave a complimentary dinner on the 26th ult. to Mr. G. H. Krumbeigel and Mr. Willie, who are departing from Kew, the former to Baroda and the latter to the botanic stations on the Gold Coast. Some forty-seven persons, including several old Kewites, sat down to dinner. The gathering included representatives of England, Ireland, Scotland, Wales, Germany, Belgium, France, and Switzerland.

— MIDLAND COUNTIES PANSY SHOW AT TAMWORTH.—Pansy cultivators are reminded that this great gathering of growers and flowers will take place at Tamworth, which is about half way betwixt Birmingham and Derby, on the main Midland line, on the 24th of this month, and the date will evidently just suit the Pansy, as the season is so very early. Violas will also be exhibited extensively at the same Exhibition. Schedules can be had from Mr. W. Dean, Dolphin Road, Sparkhill, Birmingham, the Hon. Secretary.

— PRESENTATION TO MR. M'HATTIE.—A presentation was made recently to Mr. M'Hattie, gardener to the Marquis of Lothian, at Newbattle, on his departure to assume the charge of the gardens of the Duke of Wellington at Strathfieldsaye. There was a large attendance of members of the Scottish Horticultural Association and other friends, including several ladies. Mr. Malcolm Dunn made the presentation, which consisted of a gold watch with appendages, and a purse of sovereigns, while at the same time Mrs. M'Hattie was presented with a ring.

— EARLY BLOSSOM.—Mr. W. K. Woodcock writes from Taunton:—"I see a correspondent from Bridport (page 338) sends you some Hawthorn 'nearly out in bloom.' I think hereabout it must be still earlier, for more than a week since I noticed Hawthorn fully in blossom in the lanes, and at the present date (April 28th) the double flowering scarlet and pink varieties are making a fine display in many gardens in this neighbourhood. On the walls of the dwelling houses Honeysuckle, Clematis indivisa, climbing Roses, especially Gloire de Dijon and a small yellow Rose flowering in clusters (probably Fortune's Yellow), and Wistaria sinensis (the latter past its best) are everywhere making a grand display. Chestnut trees around here are very numerous, many of them exceptionally large and fine specimens, and all are now in their greatest beauty, being very full of blossom. Lilacs and Berberis have been very full of blossom, but are now past their best. Nightingales are numerous here. In the course of a short drive a few nights since I heard five birds in full song. They come so close to the town that I hear them singing from my bedroom."

— ORANGE CULTURE IN CALIFORNIA. — According to an American contemporary Orange growing in California has developed by leaps and bounds, and the demand for trees has been so great that numbers of people were induced to start nurseries. There are over 100 Orange tree nurseries in California, with more than 400 acres devoted to the business. These nurseries contain in the aggregate considerably more than  $3\frac{1}{4}$  millions of trees, sufficient in all to plant 40,000 acres of groves.

— INSTRUCTION IN ORNITHOLOGY. — With reference to this subject on page 316, it is no new idea with me, as I have included it in my syllabus of lectures under the Agricultural sub-Committee of Technical Instruction of the Worcestershire County Council, and have given six illustrated lectures in various centres, and have mentioned about sixty species in connection with agriculture and horticulture. Every twitter and every species is quite familiar to me. I have divided them under three heads—viz., destructive birds, partially destructive, and purely innocent and useful birds. I have also shown how to bring them under control either for use or to destroy by giving suitable homes to build in. Thirteen species have availed themselves of such accommodation. I believe all "W. R. Raillem" (page 341) says of the sparrow, and more too.—J. HAM.

— THE WEATHER IN HERTFORDSHIRE DURING APRIL. — The weather during the past month in this district has been exceptionally dry, with continuous bright sunshine. The sun has put in an appearance every day, and owing to the very bright weather everything is in an advanced state of growth. Caterpillars and insects of all the leaf-eating kind are multiplying very freely. Some exceptional sharp frosts have been registered, and the Plum crop in low-lying districts totally destroyed. On the morning of the 14th I registered  $13^{\circ}$  of frost. Rain has fallen on three days during the past month. Maximum in any twenty-four hours was  $0.07$  on the 16th; minimum in any twenty-four hours was  $0.01$  on the 20th. Total for the whole month,  $0.11$ ; against  $0.88$  of 1892.—E. WALLIS, *The Gardens, Hamels Park, Buntingford, Herts.*

— HOURS OF LABOUR IN GARDENS.—Noting the correspondence in the *Journal* about the hours of labour in gardens in Scotland, and the alarm such an innovation seems to have caused some of your readers, I think it may not be out of place if I mention the way we manage the Saturday half-holiday in Rothesay. From the middle of October to the middle of March we commence at 7 A.M., breakfast half hour, dinner half hour, leave at 6 P.M.; Saturday, cease work at 2 P.M. and no dinner time. From the middle of March to the middle of October we commence at 6 A.M., three-quarter hour to breakfast and same for dinner, cease work at 6 P.M., and 2 P.M. on Saturday. From April to September one man in each department takes a turn from 2 o'clock on Saturday till 5 P.M. to attend to customers, for which they are paid overtime at the usual rate. During the winter half year the one whose turn it is to be on duty at the fires does what is required in other ways. This arrangement works smoothly. Although the firm (Dobbie & Co.) lose an hour a week during the winter on each hand, during the summer there is no loss.—ANGLO-SCOT.

— SATURDAY HALF-HOLIDAY.—Your correspondent "J. L. B." (page 336) asks, "What do the young men intend to do with the houses when they leave off at dinner time?" I desire to inform him that they intend to do their duty. No young gardener who takes any pride in his work would entertain even the slightest idea of leaving his houses either open or shut from Saturday noon till Monday morning. It would be interesting to know whether such a thing as Sunday duty is in vogue in the locality in which "J. L. B." resides, or does he leave his houses to take care of themselves from four o'clock on Saturday afternoon till the men resume their duties on Monday morning? I thoroughly agree with Mr. Thorne (page 316) that the young men should take their turn to do duty on Saturday afternoon the same as on Sunday. Where the glass houses are extensive I would suggest that two men should take duty during the summer months. Your correspondent then goes on to say, "If they are to have a holiday, why not have it in the middle of the week or once a fortnight." It is well known that Saturday is the day universally set apart for a general cleaning for Sunday, therefore this argument alone should be sufficient to commend the end of the week as the most suitable. Then, again, by leaving work at noon on Saturday the men have an opportunity of visiting their friends and returning on Sunday. I venture to assume that a half-holiday in the middle of the week would be practically useless to the young men in the country and outlying districts.—P. A. L.

— KÖELREUTERIA PANICULATA.—This, says Mr. John Wilson, Leazes Park, Newcastle, is rather a singular looking, small tree. It comes from the North of China, and was introduced into British gardens in 1763. It is of deciduous habit; the leaves are imperi-pinnate, with leaflets ovate and coarsely toothed. It is quite hardy. From July to September it produces in considerable abundance small yellow blossoms arranged in terminal, spreading, conspicuous racemes. In October the flowers are succeeded by large, lightish brown, bladderly capsules. The young wood is also brown, and the leaves ripen to a fine deep yellow in the autumn before they fall. The plant thrives best in a light warm soil, where there is shelter from the blasts, and is particularly useful where the subsoil is chalk. The handsome foliage, yellow flowers, and general manner of growth, renders the *Köelreuteria* a picturesquely conspicuous object in the pleasure ground when it has been judiciously placed. It is a plant easily propagated, either from cuttings of the roots and branches, or from seeds, and can be rendered very serviceable in sub-tropical gardening. It is seldom met with having tree-like dimensions, but not unfrequently as a shrub 8 or 10 feet high. It requires a little special attention when young. The name is in honour of J. G. Köelreuter, a distinguished German botanist.

— THE GREAT RAINFALL IN QUEENSLAND.—If we have been short of rain on our side of the world lately it does not appear to have been the same "down under." Mr. Clement L. Wragge, the Government Meteorologist of Queensland, writes to the "*Daily News*:"—"I send a few particulars of the recent remarkable rainfall at Crohamhurst, situated on the western slope of Mount Blanc, a peak on a spur of the D'Aguilar Range, an offset from the Blackall Ranges, South Eastern Queensland. The whole of this district is watered by the Stanley River, a tributary of the Brisbane River, and hence the values given below were prominent factors in producing the terrible floods from which we have suffered. I may mention that the observer at Crohamhurst is Mr. Inigo Owen Jones, one of my specially trained assistants, and that implicit reliance can be placed on his figures. The following are the more remarkable falls of the flood period at Crohamhurst: For twenty-four hours ending 9 A.M. Feb. 1st,  $10.775$  inches; ditto, Feb. 2nd,  $20.056$  inches; ditto, Feb. 3rd,  $35.714$  inches; ditto, Feb. 4th,  $10.760$  inches. The gauge is a standard of the '8-inch pattern, standing 1 foot above the ground, at an altitude of about 1400 feet above mean sea level. The approximate latitude and longitude of Crohamhurst are  $26^{\circ}50'$  S.,  $152^{\circ}55'$  E. The gauge was emptied every three hours, night and day, on the occasion of the greatest fall. I think meteorologists will agree that for a twenty-four hours' fall we have beaten the world's record."

— A REMARKABLE APRIL.—Had the weather been more cloudy than it was, the month would probably have been quite cold, but the abnormal presence of bright sunshine served to keep temperature unusually high, more especially in the daytime. Taking the mean of all the minimum, or night, readings observed in London, equally high, or even higher, temperatures have been recorded in seven out of the past twenty-two years. The day readings give, however, a very different result, the mean of all the maximum temperatures being  $2^{\circ}$  higher than in any April of the past two decades, while the absolute maximum of  $82^{\circ}$ , recorded on the 20th, was undoubtedly the highest April reading on record. The most remarkable feature of all in the weather of last month was, however, the great deficiency of rainfall. As regards the London district it appears that last month was by far the driest April experienced for at least eighty years past, the total rainfall being only one-tenth of an inch. The nearest approach to this was in the year 1855, when April showers yielded just double the quantity of rain experienced this year. The effects of the April drought have been so seriously aggravated by the dry weather of March that a brief review of the conditions prevailing during the whole two months may be of interest. It appears then that over nearly the whole of the eastern, central, and southern parts of England, and also in the south of Ireland, the aggregate rainfall for March and April amounted to less than one-quarter of the average, and over a considerable portion of the English districts to less than one-fifth. In London and at Cambridge there was only 15 per cent. of the normal quantity, and in the Scilly Islands only 9 per cent., while at Oxford and Dungeness the proportion was as low as 7 per cent. The remark has of late been heard that after so unusually fine and dry a spring the summer months are nearly sure to be wet and inclement, and it is therefore consoling to find from an examination of the records that gloomy forebodings of this kind have no warrant in actual fact.

— THE THORNS.—These hardy trees are in bloom everywhere, and in rich profusion. Generally they are fully a fortnight earlier than usual, for it is quite unusual to have them in full bloom in April, although at the end of it. It is not merely the Thorns, however, for we have Laburnums, Mountain Ash, Lilacs, and myriads of similar trees in full bloom. Also in April, and by the 1st of May, not only Apple but Crab bloom in all directions about London will be past its best. If the tree-flowering season is an early one it has been because of the fine weather a very beautiful one. Still, because of the dry state of the soil and the atmosphere, a brief one. All the same it bids fair to leave behind a good profusion of fruit.—D.

— HAZEL-BUD GALL MITE.—I have read the article on page 320-1 with much interest, and it is very singular that Mr. Gibbon of Scaford Grange, Pershore—who has paid great attention to the Black Currant gall mite—and I were chatting about this subject on our return from the Toddington gathering, and he was under the impression that they were the same as the Nut phytoptus. Having never met with the Hazel Nut phytoptus in this locality, it was no less strange that as I was returning home, examining fruit trees right and left on the way, I came across some bushes badly infested. I obtained specimens, but unfortunately lost them. I intend getting other specimens for investigation under the microscope. I am very much interested to see the reference to Mr. Harrison Weir and myself, and our ideas as regards canker in Apple and Pear trees being caused by *Phytoptus mali* and *P. pyri*, and if Mr. G. Abbey can help me in fathoming these matters I shall be only too pleased to send specimens in illustration. There is immense damage done to Apple and Pear trees in this locality which might be cleared up. I feel sure from long observation and much writing—as readers know too well, probably—that the damage, or canker, is not attributable to the soil or the roots, as I get rid of canker on different lines and ideas, and no amount of writing can upset facts.—J. HAM, *Redditch*.

— THE APPLICATION OF WATER TO NEWLY POTTED PLANTS.—There is no period in the growth of a plant that requires such especial care as to the application of water as when newly potted. In the case of hardwooded plants it is very necessary to be certain that the ball of soil is in a proper condition as to moisture before repotting. No amount of water given after will penetrate the old ball if it was dry at the time of repotting. If the soil in which the plant has been potted was moderately moist I do not consider it advisable to apply water until the plants have somewhat recovered the slight check necessarily caused by the operation of potting, free watering not being essential until perfect vitality is restored. A free watering would only cause the soil to become sour, and consequently unfitted to the wants of the plants. If the plants are sprinkled lightly and the pots kept moistened until the roots are in a more active state this will be found a safe method for the cultivator to adopt. When he is satisfied that the roots are becoming thoroughly active, let a good watering be given to moisten the new compost. When this has been done carefully observe the gradual progress the plant is making, and increase the supply as it becomes necessary. I want to impress particularly upon all young gardeners who have an earnest desire to become good practical men how very important it is to study carefully the watering of plants.—B. CROMWELL.

— HORTICULTURAL CLUB.—A special dinner and conversazione was held at the rooms of the Club, Hotel Windsor, Victoria Street, Westminster, on Tuesday, when the chair was taken by Sir John T. D. Llewelyn, Bart., the Chairman of the Club. The special was to entertain M. Henri Correvon of Geneva, who had delivered a lecture on Alpine plants at the Royal Horticultural Society's meeting at the Drill Hall in the afternoon, but in addition several other gentlemen from abroad were present as guests—Mons. Froebel of Zurich and the Messrs. Seidel of Dresden. There were also present of members and their friends the Rev. W. Wilks, Dr. Power, Messrs. Philip Crowley, Henry Letholm, H. J. Pearson, Harry Turner, Edward Crichtett, Harrison Weir, H. Selfe Leonard, J. Morten Smith, A. L. Wheeler, J. S. Cousens, and others. The tables were beautifully decorated with some grand masses of hybrid Rhododendrons, which the Chairman had most kindly had sent from South Wales, and which arrived in great freshness, while Mr. Webber of Covent Garden sent some specimens of Tasmanian Apples and also a dish of Ribston Pippins (English grown) to compare with the Tasmanians. It was generally conceded that, although the foreigners looked well, in point of flavour they were greatly inferior. The Chairman gave the toasts of "The Queen" and "The Visitors," to

which Messrs. Seidel, Correvon, Power, and Letholm responded. Mr. H. J. Veitch gave the toast of "The Club" and of its "Secretary," who proposed that of the "Chairman," and a vote of thanks to him for his great kindness in sending the flowers.

— THE HOME PARK, HAMPTON COURT.—The Chief Commissioner of Works has announced that the truly splendid park, which has a frontage of some two or more of miles to the Thames opposite Kingston and Thames Ditton, and extends from Kingston Bridge to Hampton Court Palace, is to be opened to the public on and from Whit-Monday next. That is a great concession, and the gain, not merely to the local residents, but also to the metropolitan millions, will be enormous. The area of the park is some 800 acres. It contains grand avenues of Lime trees, and, so far, is entirely devoid of all formal aspects in the shape of roads or pathways. Kingston, which has the finest river frontage for pleasure purposes on the Thames, thus becomes the centre of such magnificent open spaces as Richmond Great Park, the Home Park, and Bushey Park, in addition to the beautiful gardens at Hampton Court. The famous Chestnut avenue in Bushey Park is just now in exceeding beauty.—A. D.

### STROBILANTHES DYERIANUS.

WHEN exhibited at the Drill Hall on Tuesday, April 25th, by Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea, this new plant attracted much attention, and the Floral Committee of the Royal Horticultural Society awarded a first-class certificate for it. The plants exhibited, and from a sketch of one of which our illustration (fig. 66) has been prepared, were rather small, but sufficiently large to discern their usefulness for decorative purposes.

*Strobilanthes Dyerianus* will undoubtedly form a valuable addition to the list of stove plants. In general appearance it resembles some of the *Bertolonias* so far as the colouring of the foliage is concerned. The leaves on the plants shown were from 3 to 4 inches in length, and an idea as to their shape may be gathered by referring to the engraving. The upper surface is covered with papillæ, from which rise very minute hairs, the colour being rosy lilac with prominent dark green veins.

### NOTES BY THE WAY.

THE history of a notebook is too often the history of good resolutions made and broken. A line on this page indicates an intention to do justice to a noteworthy trade exhibit, and on that to call attention to some point in private practice which merits recognition; but neither has been fulfilled. Matters of pressing moment cause them to be passed over for the time being, others crop up in succession, and so the fierce light of publicity never beats upon them, unless, perchance, an editorial ultimatum should chance to arrive, causing a resort to be made to the forgotten pages. Nothing, perhaps, could tell us so eloquently how much we are the creatures of the hour as a notebook. It is a record of impressions which pass away as rapidly as they come, leaving behind them nothing but a memory. The revolutions of the social wheel become more and more rapid, and in its ceaseless whirl there is little opportunity for pausing to pick up the threads that have once been allowed to fall.

We do not, perhaps, feel the rush of affairs so much in gardening as in some other circles. It affects us to a certain extent, but we jog along a little more comfortably than, for example, the money men, the lives of many of whom are a misery to themselves and to everybody connected with them. After all we display better taste in worshipping a floral goddess than a golden calf. But there is less food for comment at the service of the writer. Should there be the slightest symptom of a lull in finance, behold it is destroyed by some fresh crash or more than usually brazen and colossal swindle. The financial writer has rarely to cast about for subjects, with or without the notebook. He generally has an extensive collection from which to choose, affording free scope for his talents, and often of painful interest to a large section of the public. The gardening scribbler fishes in calmer waters and hooks more gentle prey. His notes are quiet instead of exciting, and awaken at the most a mild interest. His subjects do not involve the prosperity of his readers. In short, he writes peacefully (save on certain occasions) on a peaceful art, and it is good indeed that it should be so.

Duke of Buccleuch is a noble Grape, but it is not so often seen in good condition as to make an example of strikingly successful practice unworthy of mention; on the contrary, its character is sufficiently well known to render instances of success particularly interesting. The Duke is aristocratic by name, and is generally held to be decidedly aristocratic by nature, requiring special treatment to bring out its good qualities, but that it is not always so exclusive in its tastes is proved by the manner in which it flourishes and fruits at The Grove, Great Baddow, Essex, the charming residence of Robert Miller, Esq., under

the care of Mr. William Picksley. It shares a span-roofed house about 50 feet long and 20 feet wide, with such a heterogeneous mixture as Madresfield Court, Mrs. Pince, Alicante, Gros Colman, Black Hamburg, Museat Hamburg, Black Prince, and Buckland Sweetwater. It was planted about twelve years ago, and the roots inside the house having access to an outside border. Up to three years ago the Vine was cut down annually, but Mr. Picksley did not continue the system when he took charge, and the change in the Vines under his management is very remarkable. Two rods have been taken up, reaching the ridge in three stages. The Vine is fruited on laterals managed on the usual spur system. Last year 29 lbs. of Grapes were cut from a length of 15 feet of rod, and notwithstanding that this was somewhat heavy work the Vines have again a wonderfully fine show, and promise to bear a magnificent crop. The strength of the laterals is very striking. They are long and exceedingly stout, many being half an inch in diameter at the base. The foliage, too, is finely developed. It is quite evident that the holding soil suits the Vine, but nevertheless Mr. Picksley deserves the heartiest

Chaffey Brothers has organised "down under." I wonder if Mr. A. H. Pearson is going to have anything to say about his Russians at Chilwell this year. Hitherto they have not fruited.

Accounts have reached me of Mr. Gumbleton's Tulips which have caused the one little feeling of discontent with the season that I can bring myself to entertain. Had they not been hurried on so quickly by the wonderful weather, but had bloomed at the average season, a long deferred trip to the Emerald Isle might have become an accomplished fact, and had it been possible of arrangement be sure that a visit to Belgrove would have formed an important feature of it. Those who are acquainted with the Irish amateur, and he is not an infrequent visitor to English shows and nurseries, are aware that he has his peculiarities, one of them being an outspokenness not always relished; but he is a true florist, and no pains seem to be too great when the achievement of some special object is in view. Lately he has set his heart on having an altogether exceptional display of Tulips, and he has shirked

FIG. 66.—STROBILANTHES DYERIANUS.

commendation for the way in which he has managed it. He has succeeded where many other good fruit growers have partially or completely failed. It will be of interest to note the future career of Mr. Miller's Vine. It is more than likely that if a time for severe restriction came it would begin to lose its vigour, but it is wisely being allowed to "have its head," and is now making its way down the other side of the roof. When it gets to the bottom it would not be a bad idea to let it work back again.

There seems to be an exceptional set of Apricots this year. Wanderings into various districts reveal the pleasant fact that fruit is thickly clustered on most of the trees, and the crop of 1893 should be a fine one. In some instances the set is quite remarkable, and will necessitate severe thinning. When to do this is the point. If done at once the fruit removed is worthless, but if some are left to swell until on the point of stoning they can be utilised for tarts and other culinary purposes. The mere addition of a little pulp will not hurt the trees, and so long as the strain of stoning is saved, the fruit may be left on as long as possible. I do not know if any readers of the *Journal* have tasted imported Apricots, but some fruit received from the Irrigation Colonies in Australia was really excellent. It had not a Moorpark flavour, but it was very good for all that; and Apricots on the table in winter and early spring make a most acceptable addition to the bill of fare. We shall hear more yet of the enterprise which the engineering skill of the

neither trouble nor expense in order to produce it. That I happen to know, for Mr. G. is one of those men who like others with corresponding tastes to share his pleasures. One large border in his garden, containing nearly 1600 bulbs in eighty-eight varieties has, I understand, been a dream of beauty, and Tulip lovers will be prepared to accept the description without cavil. If the early Tulips have not the special interest and qualities of the late varieties, about some of which we shall doubtless be shortly hearing something in these pages, they are still both beautiful and varied, capable of giving very rich effects in spring flower gardens.

At a recent meeting of the Royal Horticultural Society Mr. Bunyard pointed out to me a tiny plant in a collection of hardy flowers on which he said one firm had spent a round hundred pounds in vain attempts to establish it, and which another could only manage by annual importations. I venture to think that such plants should be done without. What is there in *Eritrichium nanum* that money should be poured out upon it like water? It is not unattractive, but compared with *Myosotis dissitiflora* it is a weed. Surely it is fostering a false taste to encourage attempts to cultivate plants which are conspicuous only by their fastidiousness. To say that a firm can only maintain a supply by annual importations practically means disappointment to every buyer, for if skilled growers cannot succeed with it what chance have others? Attempts to cultivate such plants as this by those who know its

character, are made, not to find pleasure in its beauty, but to outdo others. It is not an artistic but a sporting matter. It is hardly for an Englishman to take exception to wholesome rivalry, but there is not the healthy tone about this kind of thing which one can appreciate fully.

Was there ever such a dearth of "places" in the spring as exists this year? There seems positively to be nothing moving, and the sickness of hope deferred must be finding its way to the hearts of those who are waiting for something to turn up which will give them an opportunity of getting into harness again. Of all men, gardeners are the least anxious to eat the bread of idleness. They love their profession and find joy in their labour. They do not fight for high wages or special privileges. A tithe of the conditions demanded by the average trade unionist would more than satisfy them. It is hard, therefore, that those who are able and deserving should have to stand idle in the market place, waiting and still waiting for the openings that do not come. Why is it? Last year such a state of affairs could have been understood, for the cloud that gathered over the heads of the reigning family spread and had far-reaching influences, but this season no such calamity has occurred to disarrange the springs of society. It is likely enough that the financial troubles of which all men wot are largely responsible for the stagnation. Crash after crash has come in quick succession, and one establishment after another has been reduced to meet the exigencies of altered circumstances. Let us hope that the lowest depth has now been reached, and that a feeling of security will gradually grow up to replace the uncertainty and suspicion of the present. Foreign mines and foreign rails may seem to have but little connection with British gardening, yet swirls in the financial stream extend far beyond the limits of everyday vision.—W. P. W.

### TOMATO GROWING.

[By Mr. E. D. SMITH: read at a meeting of the Sheffield Chrysanthemum Society.]

PARALLEL with the advance of the Chrysanthemum the Tomato has risen in popular favour. The reason of its popularity is not far to seek. It is an easy plant to grow, and the results secured generally compensate for the time and trouble expended in its cultivation. Not only can fruit be secured which is attractive and ornamental in appearance, but possessed of highly nutritive qualities, establishing it at once as a most important article of diet.

Viewed commercially from a wide standpoint the cultivation of the Tomato has become to be a stupendous industry particularly in the United States of America, where, without much trouble and under outdoor conditions, immense crops of fruit are produced, the surplus of which by the process known as "canning" is distributed in the markets of the world. Here, in this country, but chiefly under glass, many industrious men succeed in producing profitable crops, which for excellence of flavour, beauty of form, and richness of colouring, perhaps surpass the outdoor produce of more favoured climates. In fact, there are very few lovers of Tomatoes who do not prefer English grown fruit to any that reaches here from foreign parts, this being explained when we know that fruit that has to travel must be gathered before being ripe, consequently the flavour is deficient.

### RAISING TOMATO PLANTS.

As a rule, seedlings form the best plants. For the main crop the best time to sow the seed is early in March. Early crops can be had by sowing the seed in January, but progress is somewhat slow, and requires extra care, heat, and attention. Tomato seed germinates quickly in a temperature of 60° to 65°. Sow the seed thinly on the surface of 6-inch pots, well drained, and filled firmly to within an inch of the rim with light sandy soil and leaf mould. Water gently, allowing the moisture to drain away, then scatter the seeds not less than an inch apart, covering lightly with soil, gently pressing it level. Darken the pot with glass and paper until the seedlings appear, standing or plunging the pots on a moist base of cocoa-nut refuse to prevent undue drying of the soil. Further watering will not be required until the seedlings appear. Light becomes absolutely necessary to Tomatoes immediately the first seed leaves protrude above the soil. The best place for them at this stage is on a shelf, close to the glass, in a warm structure. In a temperature of 60° to 65° they will grow rapidly. In a shady position and a confined temperature the seedlings lengthen unduly; instead of being sturdy, erect, and showing stem roots, they are flabby and soft.

When four leaves have been made they are ready to put singly in 3-inch pots, or several round the edges of larger pots. Sink the seedlings in the soil up to the pair of seed leaves. The advantage of having kept the little plants sturdy up to this point will be seen in the tendency of the young stem to throw out rootlets, especially at the base, also higher as the stem strengthens. These additional roots at this period coming to the assistance of the plants are of immense advantage in building up strong plants, which will produce flowers and set fruit early, continuing to do so throughout the season. The Tomato is naturally a soft-wooded plant, and growth must to a certain extent be solidified as it is made—not as in the case of some plants, first make the growth, to be afterwards ripened. This shows the importance of air during every stage of growth. Any lack of this important element is at once seen in soft growth, long-jointed and weak, but a due amount of it buoyant and free, aided with light and heat, will produce good plants. It is no mere assertion to say that light, air, and water are of more importance than the nature of the

soil. The Tomato will flourish in a very small quantity of the latter, but of the former it must have no stint.

### POTTING THE PLANTS.

Passing on now a stage further, it will be found that when the young plants have strengthened themselves in small or other pots they are usually large enough to be transferred to 5-inch pots, from which size they are the most conveniently taken for the final potting or planting out. Drain the pots lightly, and in potting place the plants low down as for previous shifts, so that some portion of the stem is again buried in fresh soil. The compost for this shift may be fairly rich and good, turfy loam being its main constituent. A little bonemeal, at the rate of a pound to a bushel of soil, may be added in preference to decayed manure, also a little sand and burnt refuse. Pot firmly, though not absolutely hard. Place the plants on a shelf close to the glass in an average temperature of 55° to 60°. Both the soil surrounding the roots and the fresh compost being moist, there will be no need of watering for a day or two if the weather be dull, but if sunny water must be given. I find shading to be unnecessary, even if bright sunshine follows closely on repotting. Growth will soon be rapid, and care must be taken to afford water as required, this often claiming attention twice a day in very bright weather.

### FINALLY POTTING OR PLANTING OUT.

As soon as roots are plentifully formed, and the plants are still vigorous, they should be moved to their fruiting positions. It is the custom of some to defer this until the first bunch of fruit has set, but in my opinion it is not the wisest course. Directly Tomatoes become root-bound in small pots the main growth extends in a weaker manner, the succeeding bunches of bloom also suffering in size and vigour. Therefore it is much the best plan to finally pot or plant out before the latter conditions are brought about.

Pots 11 or 12 inches in diameter are the best for fruiting plants; larger or smaller sizes than those are not desirable. When smaller enough support cannot be given, while in larger stronger growth is made in the course of the season than is wanted. Excessively vigorous growth is always liable to be fruitless. Drainage for the fruiting pots may consist of a good sized oystershell placed concave side downwards over the large central hole in each, placing over this a small handful of various sized potsherds, finishing off with a layer of fibrous turf picked from the compost or prepared specially. On this, before introducing any soil, place the plant turned out from its 5-inch pot. The object should be to have the plant as low as possible, because it is an error, and would not conduce to good results, if the whole space within such large pots was at once filled with soil. Just sufficient ought to be added to surround and cover the ball of roots, making it firmer than in previous pottings. The limited amount given is ample for a time, usually until the first bunch of fruit has set and is swelling, when more may be applied. Only a slight top-dressing of a couple of inches is given each time. The same kind of compost may be used for the final potting or planting out as recommended for the previous potting.

In planting out Tomatoes the error of giving a root run too wide and deep must be avoided. I like to form a border for Tomatoes on a hard bottom such as is afforded by a slab or slate stage, with a slight fall to the front, so that superfluous water can run quickly away. In such a position no drainage is required. The depth of soil at first need not be more than 4 inches. The top-dressings subsequently given will raise the bulk a little higher during the season. Contract the width of the border as well as the depth, 14 inches being a good width. The size of plant for placing in fruiting positions is important. When turned out of pots larger than 5-inch into a border too much soil has to be introduced, as it is obvious the balls of roots must be covered. For planting out I prefer plants from 4-inch pots. Quite sufficient soil can then be packed round and made firm without overloading.

Never pot or plant out Tomatoes unless the soil and roots are thoroughly moist. The fresh soil also should be in that intermediate state of moisture, which gardeners know so well to be neither wet nor dry. Surrounded with this friable and sweet material the roots soon make progress and take full possession.

(To be continued.)

### THE ROYAL GARDENERS' ORPHAN FUND.

#### ANNUAL DINNER.

As briefly announced in our last issue the supporters of the Royal Gardeners' Orphan Fund held their annual dinner at St. James' Hall, Regent Street, W., on Wednesday, April 26th, under the distinguished presidency of Baron Ferdinand de Rothschild, M.P. Although but yet in its infancy, this excellent charity has made considerable progress during the comparatively short period it has been in existence, and as on previous similar occasions, the festival was a great success. About one hundred gentlemen were present, and amongst others we noticed Sir T. Lawrence, Bart., Sir J. T. D. Llewellyn, Bart., Rev. W. Wilks, Major Foster, Major Sexey, Lieutenant Pott, Dr. Walker, H. J. Veitch, Esq., N. N. Sherwood, Esq., P. Crowley, Esq., Messrs. T. Manning, A. G. Manda, F. Sander, G. J. Ingram, H. E. Milner, H. Turner, H. Williams, E. D. Shuttleworth, A. F. Barron (Secretary), J. T. Anderson, J. Assbee, H. Balderson, W. Y. Baker, P. Barr, F. Bausé, G. Bunyard, R. Cannell, W. L. Corry, W. W. Cousens, H. J. Cutbush, W. Denning, J. Douglas,

H. P. Glendenning, H. Herbst, W. Iceton, P. E. Kay, F. Q. Lane, W. Marshall, G. Monro, A. Moss, W. N. Nutting, W. Poupert, E. Rochford, S. M. Segar, J. Smith, G. F. Strawson, J. Sweet, O. Thomas, A. W. G. Weeks, J. Wills, J. Willard, and J. Wimsett. The tables were beautifully decorated with flowers and fruit kindly supplied by Messrs. B. S. Williams & Sons, J. Laing & Sons, F. Sander & Co., Wills and Segar, H. Cannell & Sons, J. Walker, G. Wythes, and J. Smith.

The Chairman, after the customary loyal toasts, proposed the toast of "Success to the Royal Gardeners' Orphan Fund," associating with it the name of Sir J. T. D. Llewelyn, Bart. Baron Rothschild said he need hardly tell the company what the nature of the Institution was, because they were all acquainted with it. It was, however, comparatively speaking, an infant among the many charitable institutions of the great metropolis; it was not only an infant, but it might also be described as a dwarf, but age would diminish the fault of its being an infant. (Hear, hear.) They were assembled together that evening to obviate that defect in the stature of the institution, and by their generosity to enable it to increase its size to the proportions of a giant. The infant had, in his opinion, done very well during the first few years of its existence. He was pleased to know that during the past year it had given weekly allowances of 5s. to fifty-six children under fourteen years of age, which distribution represented an outlay of £750. (Applause.) That was, he considered, a most creditable piece of work. The metropolis abounded with not only hospitals, but homes and charitable institutions of every kind. He knew that that evening there were several dinners being held in the City in aid of similar institutions, and the pockets of the benevolent were always being called upon to keep pace with the growing demands of charitable causes. In spite of these numerous dinners, however, they were gathered together that evening in the interests of the Royal Gardeners' Orphan Fund, and he looked forward confidently to an excellent result in the shape of subscriptions. (Hear, hear.) The charity, as they all knew, had been established for the maintenance of gardeners' orphans, and although the occupation of gardeners was a good and healthy one, yet they were exposed to certain risks which often left children fatherless, and therefore orphans. He did not know what the statistics of gardeners' lives were, but in the proper execution of their work in hothouses, and during the night time, gardeners caught chills, and died sooner, perhaps, than might be expected. Gardeners were, moreover, frequently transferred from one place to another, and were thus compelled to reside in localities that were perhaps the reverse of beneficial to them. He was not aware if the children of gardeners travelling about the world in the course of their occupation were included among those benefited, but if not, he certainly thought they ought to be. Who knows, the Chairman said, but that the men who had administered to our luxury in gardening had contracted some disease? For instance, he had an Orchid in his coat that evening, and no one knew whether a man had not died in the discharge of his duty in some foreign land; if it was so, the children of that man should be as well looked after and cared for as those of a gardener who had died at home. (Hear, hear.) He considered the opportunity of allowing the orphans a sum of £10 when the weekly allowance ceased, when the children had arrived at the age of fourteen, a most excellent measure, for it was just the time when boys were becoming young men and when girls were growing into womanhood, that £10 would be almost a means of salvation to them. It may happen that £10 judiciously laid out at that period of a boy's life may be the means of producing some great man to whom they would be indebted. He did not believe there was a charity throughout the length and breadth of the country which was more economically administered than this Fund. (Applause.) By a reference to the report they would see that the cost of the Institution had been quite trifling compared with the expenses of others. He was bound to say, therefore, that the balance-sheet was a credit to the charity. At the dinner last year the handsome sum of £1000 was subscribed, and the Chairman on that occasion possessed some rich relations and friends in the City, but although he had done his best his influence had not been quite so successful as that of Sir James Whitehead. Last year, continued the Chairman, his friend Mr. Veitch celebrated his silver wedding, and in memory of that auspicious occasion he presented the Fund with a splendid donation of £500. (Applause.) He hoped that other gentlemen present had that year celebrated their silver wedding, and looking around him he did not think that any of them had celebrated their golden wedding yet, or he might look perhaps for a donation of £1000. (Laughter.) He trusted, however, that Mr. Veitch, when he celebrated his golden wedding, which he sincerely hoped he would do, would make a donation perhaps of £1000. (Applause.) He would conclude by pointing out that if each of the hundred gentlemen present added four times 5s.—he would not call it a pound—it would mean an additional £100 to the sum which had been promised. If gentlemen were to realise this fact it would be the means of relieving the sufferings and raising the hopes of many a young man and many a young woman. The Chairman subsequently announced that Mr. Sherwood had handed him a cheque for £100 as a donation to the Fund. (Applause.)

Sir J. T. D. Llewelyn, Bart., in responding to the toast, said the institution was doing an immense amount of good, and as one of the Trustees he was sure no one had the welfare of the Fund more at heart than he had. It ought to be remembered that the parents of the orphans they were called upon to assist had taken their share in gardening. The profession of gardening had made very rapid strides during the past half century, and no one could say where it was going to end, to what

extent it would grow, and what further improvement would take place in fruit and flowers and vegetables. Kew had set a valuable example in horticulture; indeed, it had been the means of greatly improving the welfare of the people living in the colonies, and the value of those colonies to a very appreciable extent. (Hear, hear.) This, he thought, was sufficient evidence as to the beneficial results of gardening, and those who represented the "upper ten" of horticulture should not forget that it was part of their duty to make the existence of orphans a little more tolerable. The work which had been done through the Fund proved how much lay before it in this direction. In 1887 the Fund was started, and a commencement was made with the election of eleven children. The number grew in the following year to thirty, and from thirty to fifty, and last year eight more were elected, making a total of fifty-eight, and only two had arrived at the age of fourteen. Fifty-six children were therefore on the books of the Fund, and if it progressed in the same ratio year by year there was a great future before it. (Cheers.) All should put their shoulder to the wheel, and much more might then be done. The most satisfactory feature during the past year's operations was that H.R.H. the Princess of Wales had graciously consented to become Patroness of the Fund, expressing at the same time a hope that the association of her name with it might be the means of benefiting it. This had clearly been the case, for their excellent Secretary, Mr. Barron, had now secured the Duke of York and the Duchess of Albany as life subscribers; that was the first fruit of the Princess of Wales being Patroness of the Fund, and he doubted not that it would bring a further accession of supporters. (Applause.) The handsome donation which Mr. Veitch presented to the Fund could not fail to have a good influence upon the leaders in the horticultural world, and he confidently looked forward to their patronage. He thought also they might approach the professional gardeners of the country. During the five years the Fund had been in existence the sum of £6570 had been invested. The value of such an invested sum as that could not be over-estimated, especially in the future if subscriptions did not come in so readily, although he hoped the day was far distant when they would be compelled to touch the capital, at the same time it was most desirable to have such a sum invested. (Cheers.)

Sir Trevor Lawrence, Bart., gave the next toast, that of "Gardeners and Gardening." In doing so he said the British people could fairly lay claim to the possession of the most beautiful gardens and the most skilful gardeners. (Hear, hear.) He had travelled about a great deal, and he had frequently been asked to go and look at some garden that was thought beautiful in the locality he might for the time be staying; but although he had seen some fine gardens he could honestly say he had never seen anything on the Continent equal to what could be found in this country—(applause)—indeed, he believed the British had established throughout the world their reputation for the highest form of cultivation and the good standing of the calling of a gardener. Whether one went to the northern or southern part of these isles the same thing was noticeable. The sentiment applied also to cottage gardens, which sometimes succeeded in producing plants which the park or mansion could not do, and one of the great attractions about a garden was that whether it was large or small the owner felt an equal pride in it. He thought there was as much pleasure derived by the owner from a few plants in a window as from a large garden. (Hear, hear.) Referring to his recent visit to the Ghent Quinquennial Sir Trevor remarked that although the Show was a very good one, and the Belgians the most hospitable race in the world, he had no hesitation whatever in declaring that English horticulturists could do equally as well, and he ventured to say a great deal better. (Hear, hear.) He trusted that as long as England lasted the beauty of her gardens would be maintained, and, further, that the interests of such an excellent and most intelligent body of men as the British gardeners would never be forgotten. (Applause.)

N. N. Sherwood, Esq., responded to the toast, and said he almost felt the wrong man in the right place. He could not call himself a gardener, but he rather wished he was able to do so, after hearing the high praise Sir Trevor Lawrence had showered on British gardeners. He expressed a hope that gardeners would always gain the approbation of gentlemen like the Chairman and the proposer of the toast, and that the Fund would ever receive the support and sympathy of such distinguished men. He was sure that gardeners in this country could hold their own. It was quite true that gardening had made immense progress during the past fifty years, and it was not to be surprised at when they remembered that almost every little village and provincial town in this country had its flower show; and then looking at the magnificent show that was held annually at the Temple, he thought gardeners could not help feeling proud of their calling. (Hear, hear.) With respect to the Fund itself, this happened to be the Jubilee year of the firm he represented, and he asked the Committee to accept a cheque for £100. (Applause.) He knew of a very sad case in which a poor gardener had recently died and left a family of seven children. He wished to pay for the maintenance of one of those children, and would be perfectly willing to pay down in a lump sum the amount which was necessary for the maintenance of the little orphan for the next seven or eight years. (Applause.)

Dr. Walker proposed "The Chairman," and briefly remarked that they all knew that Baron Ferdinand de Rothschild was always ready with his assistance when the interests of horticulture were at stake, although he did not give that indiscriminate charity which did more harm than good.

The Chairman in responding said that he had always taken great interest in gardening, and after many dreary hours of parliamentary duties he fully appreciated his garden. Mr. R. Dean submitted the

toast of "The Visitors," to which Mr. J. Collingridge and A. White responded.

Mr. A. F. Barron, the Honorary Secretary, announced that the subscriptions promised that evening amounted to £490. The donations included—Baron F. de Rothschild, £50; Messrs. Hurst & Sons, £100; Messrs. Rothschild, £25; Sir John Llewelyn, Bart., £10 10s.; Sir Trevor Lawrence, Bart., £10 10s.; Mr. F. Sander, £18 18s.; Messrs. J. Veitch and Sons, £10 10s.; Mr. G. Munro, £14 14s.; Mr. J. Wills, £10 10s.; Mr. W. Marshall, £10 5s.; Mr. J. Wimsett, £10 10s.; Mr. R. Dean, £10 10s.; Mr. F. Q. Lane, £9 8s.; Mr. A. W. G. Weeks, £8 1s.; The Thames Bank Iron Co., £9 9s.; and numerous other smaller sums from various supporters of the Fund.

#### ROSE SHOW FIXTURES IN 1893.

- June 20th (Tuesday).—Westminster (N.R.S.).  
 „ 22nd (Thursday).—Ryde.  
 „ 28th (Wednesday).—Clifton,\* Earl's Court, and Richmond (Surrey).  
 „ 29th (Thursday).—Eltham, Newport, and Windsor.  
 July 1st (Saturday).—Crystal Palace (N.R.S.).  
 „ 4th (Tuesday).—Bagshot, Canterbury, Diss, and Gloucester.  
 „ 5th (Wednesday).—Croydon, Dursley, Ealing, Hereford, and Lee\*.  
 „ 6th (Thursday).—Bath, Farningham, Norwich, and Sutton.  
 „ 7th (Friday).—Hitchin.  
 „ 8th (Saturday).—Reigate.  
 „ 11th (Tuesday).—Harleston and Wolverhampton.†  
 „ 12th (Wednesday).—Earl's Court and Tunbridge Wells.  
 „ 13th (Thursday).—Worksop (N.R.S.), and Woodbridge.  
 „ 14th (Friday).—Helensburgh.  
 „ 15th (Saturday).—New Brighton.  
 „ 20th (Thursday).—Trentham.  
 „ 21st (Friday).—Ulverston.  
 „ 22nd (Saturday).—Manchester.  
 „ 25th (Tuesday).—Tibshelf.  
 „ 27th (Thursday).—Halifax, and Southwell.  
 „ 29th (Saturday).—Bedale.

\* Shows lasting two days.

† Shows lasting three days.

I shall be glad to receive the dates of any Rose Shows not mentioned above for publication in my next list of fixtures, which will be issued early in June.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

#### PARIS GREEN FOR ROSE CATERPILLARS.

HAVING again proved the efficacy of this on Rose bushes, a reference may be of interest to some. A friend happened to be in my garden the other evening, and noticing the vigour and healthy appearance of the foliage, exclaimed, "What have you done to your Roses to produce such foliage?" I told him that I had applied poultry manure as a top-dressing in winter, and a spraying of Paris green to kill the grubs in spring. He remarked he could not obtain such, do what he might. There is something one cannot understand about the prices charged for Paris green. If I send to Worcester I am charged 2s. 6d. per lb., or 4d. per oz. in less quantities; at Evesham, 1s.; and a friend informs me he gets his at 9d. per lb. from a first-class house.—J. HIAM.

#### ROSES AND ROSARIANS.

IN my article bearing the above title in your last issue there is a typographical error which I hope you will kindly allow me to correct. In this special instance "so" has been substituted for "if," and thereby my previous arguments are practically undermined, and I am rendered logically inconsistent, which I have no special desire to be. The expression in which this error occurred should read thus: "If the great English, Scottish, and Irish rosarians are unanimous in pronouncing this magnificent Rose (Mrs. Paul) to be a pure Bourbon, I accept their verdict unquestioningly."

But on this point they are not perfectly unanimous, for several of them, as I stated in previous contributions, class this stately and imposing variety as a Hybrid Bourbon. I am quite disposed to admit, however, that the law of variation may have had something to do with the formation of Mrs. Paul; for in accordance with this law, and especially I think in the case of Roses, attributes and characteristics often seem to pass over the second generation, and are found in the third. Of course this manifest eccentricity of operation on the part of Nature may entail for the recipient either weakness or vigour, either a virtue or a vice. The former influence has manifestly been the experience of Mrs. Paul.

With reference to my theories regarding the parentage of Roses, and the phrases I have made use of in describing these, Mr. Cranston of Hereford writes to me as follows:—"Seedlings are, of course, as you have indicated, distinct from 'sports'; but a variety producing either is the parent under any circumstances." I think this decision should be held as conclusive. I am glad to have the support of so great a rosarian and so accomplished a writer upon Rose cultivation. Nor, I may add,

does he at all object to my previous assertion that the finest Tea and Noisette Roses produced in England are grown under glass.

I learn that these are at present most impressive at Waltham, and I only regret that I cannot be in London in time to see Mr. Paul's superb Roses in perfect bloom. He informs me in his latest communication that they are three weeks earlier than usual this year. I can confirm this assertion, for even in my own garden there are already many Roses visible on Gloire de Dijon, Marie Baumann, La France, Lady Mary Fitzwilliam, Etoile de Lyon, Belle Lyonnaise, William Allen Richardson, and Maréchal Niel.—DAVID R. WILLIAMSON.

#### PEAR PROSPECTS.

I AM not a large Pear grower, but I have besides those on my walls some large trees of Williams' Bon Chrétien, Pitmaston Duchess, Comte de Lamy, Beurré de Capiaumont, and Bishop's Thumb. They are all as full as they possibly can be, and a vast number fall off, but I have never in my twenty-five years' experience seen them so well set, but then the lowest reading of the thermometer 4 feet from the ground was 31° on the 13th.—D., *Deal.*

YOU ask for reports as to Pear promise. I looked in the other day upon Mr. E. Bennett, who has recently taken the extensive private walled-in gardens at Hampton Court Palace, and found on most of the standard trees there, as well as those on walls, quite a heavy set of fruit. I could not refer to varieties, for Mr. Bennett does not yet know what they are; but as these gardens are within a couple of hundred yards from the Thames the full crop is all the more remarkable. Plums in every case there are also a heavy set. I learnt over in Middlesex that Pears promised a fair crop in the market gardens. "I think," said an old and experienced grower, "we shall have a good fruit crop all round this season." That is comforting, although it is certain that rain is most badly needed.—A. D.

THE crop here promises to be the best I have seen for the last fifteen years, especially on the unprotected trees, growing as bushes in the open. Such varieties as Doyenné du Comice, Maréchal de Cour, Williams' Bon Chrétien, Comte de Lamy, Duchesse d'Angoulême, Beurré Clairgeau, and Catillac are very full of promising fruit. All varieties growing against walls, whether cordon or horizontally trained, likewise promise abundantly, especially the latter.—E. M., *Swanmore Park.*

I NOTICE several varieties of Pears, which, although well filled with blossom, are only going to carry very moderate crops. The Pear weevil has been especially destructive, also the Gooseberry caterpillar, which has completely destroyed a row of splendid bushes in a cottage garden near where I reside.—R. P. R.

#### ROYAL HORTICULTURAL SOCIETY.

APRIL 25TH.

SCIENTIFIC COMMITTEE.—Present: Mr. McLachlan (in the chair); Mr. Blandford, Prof. Green, Rev. W. Wilks, Mr. Wilson, Dr. Bonavia, Prof. Müller, and Rev. G. Henslow, Hon. Sec.

*Eucalyptus Galls*.—Mr. Blandford reported upon his examination of the large woody galls sent to the last meeting by Baron von Müller from Australia (wrongly referred to Acacia). They appeared to be formed at the base of the leaves. The gall was occupied by a large solitary coccid, the head being turned away from the orifice by which the larvæ escaped. Mr. McLachlan observed that coccids usually live externally on plants; but for some time a group has been known, including several species, which form galls on Eucalyptus in Australia, the coccids being sometimes upwards of an inch in length.

*Bardfield Oxlips Changing Colour*.—Rev. C. W. Dod sent a clump bearing several umbels of yellow and one of red flowers with the following communication. Referring to the specimens brought to the last meeting by Dr. Masters he writes: "I have during the last few years investigated many of these cases in which I used to believe, but I have come to the conclusion that if a plant growing in the same soil and position, and not having been drugged, seems to have changed the colour of its flowers, *aliquis latet error*. In the particular case of the Bardfield Oxlip, which I grow in many spare corners of my garden, I find the duration of life of the plants to be about four years. Seedlings take the place of those that die, and are often amalgamated with them, flowering all together; so that it seems that one with dull red flowers (always the first departure from the typical colour in the *Primula veris*, L., class) appears to be part of the same plant which is bearing yellow flowers. By the next year the yellow-flowering plant is probably dead, and the red-flowering one has quite superseded it." On carefully washing the mould away from the "clump" sent by Mr. Dod it was readily resolved into seven perfectly distinct plants, six bearing yellow flowers and one being dull red flowered, thus entirely corroborating Mr. Dod's account of the origin of a change of colour being by seed only.

*Erythronium grandiflorum*, giant form, &c.—Mr. Wilson exhibited a flowering spike of this plant, 16 inches in height, with leaves proportionally large. It appeared first in 1892 among some seedlings, and is considerably larger in the present year. He also showed a specimen of *Narcissus triandrus*, remarkable for its strong growth, bearing four

instead of the usually two flowers; also an umbel of a *Primula*, with the flowers dissociated along the peduncle.

*Myosotis Proliferous and Many-petalled.*—Dr. Bonavia exhibited sprays of this variety, which is now in the market. The petals are often as many as nine or ten in number, though no flower appears to be "double." Two or three flowers are sometimes fused together as in Tomatoes. An examination of this variety made by the Secretary showed that instead of the separate flowers along a common peduncle, as in the ordinary Forget-me-not, each flower is represented by a raceme, a proliferous condition sometimes seen in Solomon's Seal, Bluebells, &c. The individual flowers were characterised by "symmetrical increase," the sepals, petals, and stamens being multiplied uniformly. The pistil was malformed, consisting of a conical structure, the stylar tube being open above, with a rudimentary stigmatic border. About eight ovules were arranged in a circle at the base of the ovary, the placentation being thus free central. The terminal flower on the main axis was very remarkable, recalling somewhat similar malformations often seen in Foxgloves, Larkspurs, &c. It consisted of a whorl of many sepals, within which were five clusters, consisting of oval scale-like carpels, with a row of glands outside them; then followed in succession within the scales a mass of petals and stamens. Five similar carpellary scales then were seen around the axis, within which all round were numerous abortive ovules. The central axis consisted of a flower turned inside outwards, the members of which being in a reversed order—viz., stamens on the outside of the tube of the corolla, the corona being thus on the exterior surface, the petal lobes over-arching them outwards, while the centre was occupied by a tuft of erect sepals. Information as to the origin of this remarkable variety and the name of the raiser is greatly to be desired.

*Peach Leaves Malformed.*—Rev. F. C. Dillon sent leaves which were curled, and with a blistered appearance, the lower epidermis peeling off. It was thought to be due to a chill by east winds, and not to the presence of fungus or insects. They were referred to Prof. Green for further examination.

#### THE NARCISSI EXHIBITION AT BIRMINGHAM.

THE long spell of hot weather upset this Exhibition very considerably, and only about one-fifth of the prize money offered was won. Had it not been for the very early season, there would have been a large display.

Mr. J. W. Wilson, South Cave, East Yorkshire, was the only exhibitor in the cut bloom classes, and he had in his collections fine flowers of *Incomparabilis Eclipse*, Sir Watkin, Harry Collins, a very distinct variety; *poeticus tripodalis*, *Horsefieldi*, *bicolor grandc*, and others. The only exhibitor of Narcissi in pots was Professor Hillhouse.

There were some very praiseworthy honorary exhibits of Narcissi, which made up a small and select display. Messrs. Pearson, Chilwell Nurseries, Nottingham, had an excellent collection, which formed a striking feature, and to which a silver medal was awarded. Many of the choicer kinds were in this contribution, and it was a surprise that so many could have been kept back for the Show. In this collection were that very fine new white variety *Madame de Graaf*; also a superb deep yellow trumpet, *Glory of Leyden*, with lighter segments, a wonderfully fine flower of excellent form and substance, and to which a first class certificate was awarded. Mrs. Vincent and Mrs. J. B. M. Camm are two very fine whites, and a new white variety raised by Mr. de Graaf, named Mrs. Pope, was also in this collection. Other fine kinds were *King of the Netherlands*, *Princess Mary*, *Goliath*, and *Frank Miles* of the *Incomparabilis* section; *P. R. Barr*, a beautiful yellow of the *Empress* type; *Leedsii Duchesse de Brabant*, white, with pale sulphur cup, changing to white, and very free blooming; *Leedsii Mrs. Langtry*, a pale creamy white; *Poeticus grandiflorus*, and *poetarum*, the true Poets' Narcissus.

Mr. Robert Sydenham, Birmingham, staged a bright collection, amongst them several groups of very fine *Burbidgei*, Mrs. J. B. M. Camm, *Nelsoni major*, and others. *Barri conspicua* very highly coloured, and Mr. Sydenham also staged fine blooms of the various kinds of *Parrot* and other Tulips.

The Edgbaston Botanic Gardens contributed a group of Narcissi, chiefly such as *Burbidgei*, *Mary*, and *Robin Hood*; *Incomparabilis Glow*, *Marginata*, *Cynosure*, and *John Stephenson*; *Bicolor James Walker*, *grande* and others.

Mr. T. Jannock, Dersingham, King's Lynn, staged *Lily of the Valley* plants in jardinières, baskets and pyramids, a superb display to which a silver medal was awarded. Messrs. Hewitt & Co., nursery and seedsmen, contributed Narcissi and hardy border flowers. Messrs. Pope & Sons, nurscrymen, staged a superb bouquet of *Narcissus* blooms which obtained the first prize.

#### GARDENERS' CHARITABLE AND PROVIDENT INSTITUTIONS.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—Secretary, Mr. G. J. Ingram, 50, Parliament Street, London, W.C.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—Secretary, Mr. W. Collins, 9, Martindale Road, Balham, London, S.W.

ROYAL GARDENERS' ORPHAN FUND.—Secretary, Mr. A. F. Barron, Royal Horticultural Society's Gardens, Chiswick, London, W.

#### HIBBERTIA PERFOLIATA.

THIS interesting plant is now flowering in most gardens where it is grown, although unfortunately there are exceptions to the rule, inasmuch as *Hibbertia perfoliata* is not generally cultivated. The *Hypericum*-like flowers are bright yellow, and being freely produced renders the plant very attractive. Several species of *Hibbertia* are grown in conservatories, usually trained to pillars or the roof, but *H. perfoliata* is more compact in habit, and, like the small-flowered *H. Reedi*, is better suited for

FIG. 67.—HIBBERTIA PERFOLIATA.

culture in pots. The flowers are not of long duration, but so many are produced and in such close succession that the plant continues ornamental for a considerable time.

VINES IN GERMANY.—It is not, perhaps, generally known, says *Nature*, that the largest wine-growing district in Germany is Alsace-Lorraine. According to a report forwarded to his Government by the French Consular Agent at Frankfort, while the Wiesbaden Regency has only 7300 acres planted with Vines, which in 1890 yielded 1,644,040 gallons, the Coblenz Regency (18,950 acres) giving 3,755,220 gallons, that of Trèves (8980 acres) giving 1,832,400 gallons; Alsace-Lorraine alone contains 75,640 acres, the production of which in 1890 was 16,999,000 gallons (6,429,740 gallons in 1891), a production which is chiefly consumed in the country itself. According to the same authority the average annual production of wine in the whole world during the five years from 1886 to 1890 is estimated at 2,811,600,000 gallons. In this production Italy figures for 690,008,000 gallons, Spain for 657,250,000 gallons, and France for 606,562,000 gallons; that is to say, these three countries supply two-thirds of the total quantity produced. Germany, with an average annual production of 51,705,610 gallons, only occupies the tenth place among wine-growing countries. The value of some of her wines partly compensates her, however, for the relatively small quantity of her annual crop.

## HARDY FRUIT GARDEN.

**Summer Mulching Fruit Trees.**—The advantages of a manurial mulch on the surface of the soil round fruit trees and bushes are very apparent during hot dry weather. The rapidity of evaporation which takes place from surface soil soon exhausts the available moisture within reach of the upper roots. The result of this is that the finer and most important feeding fibres suffer considerably. Roots dislike to ramify in dry soil, and those so situated will, when the surroundings are not moist, attempt to find the moisture they need by descending to lower levels. Thus, the absence of a summer mulch encourages deep rooting, and causes strong unfruitful growth to be made in trees.

**When to Mulch.**—The best general time for applying mulching material is during May, after the ground has received benefit from the warm spring sunshine, raising the temperature of the soil for several inches below the surface. It should be applied before long-continued drought has deprived the soil of the needful moisture which is necessary to maintain healthy root action near the surface. If the soil appears too dry, the area occupied with roots ought to be thoroughly moistened, either with clear water, or if the trees are old and fruitful with liquid manure prior to spreading the mulch. The manure being sweet and of a lumpy character may be applied about 2 inches thick, spreading it in a circle round the bole, so as to cover the distant rootlets.

**Renewing Mulch to Newly-planted Trees.**—With young trees planted in autumn or early spring the mulching material then applied consisting chiefly of open, strawy material will to a great extent be dried and exhausted. The loose material may, therefore, be raked off and a little fresh substituted. Should the soil be at all dry water may be needed, and it will be best to apply it before renewing the mulch over the roots. This will ensure a moist condition of the soil for a considerable time. Apply the mulching a little beyond the points to which the roots extend, taking care that the manure used is not heavy and solid, but of a light, partly decayed character. The object with young trees is not to feed the roots but to conserve the moisture about them, at the same time admitting air and warmth to the soil.

**Mulching Stone Fruits.**—The treatment of stone fruit trees as regards the roots needs special attention, as the application of an excess of manure is very likely to produce strong gross growth and favour gumming. In applying a mulch to these, then, neutralise rich manure with loamy soil of a calcareous nature. If not possessing the last characteristic add old mortar rubbish well pulverised, or lime in some other available form. Introduce such material direct to the roots, carefully removing the soil until they are reached. See that the soil below is moist. After placing on the roots a couple of inches of compost return on the top a layer of the old soil. Weakly trees that require the growth accelerating may receive a mulching composed of manure only, or at least with less soil added. Heavily cropped trees also require extra support in order to swell the fruit, and to such a mulching of manure will be of great assistance in finishing the crop.

**Mulching Strawberries.**—It is quite time now that all beds and borders of Strawberries which have not already been attended to should be mulched with good manure. Manure containing an equal quantity of both long and short material may be used. The latter will feed the plants as well as conserve the moisture about them in hot dry weather. The former is useful for providing a clean base for the fruit to rest on when ripe.

**Watering Strawberries.**—In most soils this spring, but especially in that which is light and dry, watering will be beneficial. Liquid manure, however, in most cases will be preferable, affording a thorough soaking before mulching, or it can be done with advantage after. New plantations will need moisture in order to aid the plants to obtain good foothold before the hottest weather arrives. If manure is not laid between the rows as a mulch, keep the surface open with the hoe.

**Thinning Apricots, Peaches, and Nectarines.**—Much fruit, especially of Apricots, has received a preliminary thinning, the weather having favoured a good set, and quickly brought on the young fruit to the size of horse beans when the first removals are effected. Thinning the fruit, like disbudding the shoots, should be performed gradually, carefully eschewing all the worst-placed first and those which are behindhand in swelling. More fruit may be left on a vigorous tree than on a weakly one. The same applies to the number left on the branches. Over-vigorous parts may be considerably checked by allowing an extra quantity of fruit to remain. Weaker parts, on the other hand, may be proportionately invigorated by early reducing the number of fruits. In thinning, also take the size of the fruit into consideration. That which naturally develops to a large size thin to wider distances. Properly fertilised fruit swells the soonest; therefore retain these to the last, or until it is seen that some may be dispensed with to the advantage of the trees, and the whole can be considered safe from adverse climatic influences. The stoning period is a critical time. If any injury has been received when in a young state the fruit will drop at this time, if not before. Leave the final thinning until this important period is

past, taking care not to overburden trees with too many in order to see which will pass through the ordeal the best.

**Watering Fruit Trees.**—Newly planted trees will need sufficient moisture to maintain a healthy growth. Let the water used stand, if possible, exposed to the sun and weather for a day or two, or obtain it direct from a soft-water tank. It is always best to apply slightly aired and softened water in preference to that which is cold and hard.

**Destroying Gooseberry Caterpillars.**—When first attacked and the pests are not numerous, hand-picking is effectual to rid the trees. During the early stages dusting with hellebore powder will destroy numbers. Lime also, newly slaked and in fine powder, dredged on the under side of the leaves when damp, acts both as a destroyer of the larvæ and a deterrent to further deposits of eggs upon the foliage.

## FRUIT FORCING.

**Peaches and Nectarines.**—*Early Houses.*—Alexander or Waterloo Peaches started at the beginning of last December now have the fruit ripe, and the foliage must be kept dry until the whole of the fruit is cleared. The wood that has borne fruit and not being required for extension should then be cut out to the successional bearing shoot at the base of each, and the foliage afterwards be thoroughly washed by means of the syringe or garden engine, so as to cleanse the trees of red spider and dust. This will need to be attended to daily in bright weather to preserve the foliage in health. The soil must also be kept in a moist condition, air being freely admitted, but a very low night temperature is not advisable at present, nor too close restriction of the laterals, as upon the health and preservation of the foliage mainly depends the retention of the fruit buds during the rest period. Early Louise Peach and Advance Nectarine started at the same time are now ripening their medium-sized well-flavoured fruits. Water, of course, should be withheld from the fruit, but the trees must not be neglected for water at the roots, and moisture in the atmosphere is absolutely essential to the health of the foliage. Damp the floor and border in the morning and afternoon of fine days, and at other times when these surfaces become dry. Hale's Early Peach and Lord Napier Nectarine in the same house are advanced towards ripening and require similar treatment.

Royal George Peach and Elruge Nectarine, however, under the same conditions are swelling and colouring the fruit, and require a free circulation of air in order to secure flavour, but it should be given carefully during the prevalence of cutting winds, placing some netting over the ventilators. Elevate the fruit well above the foliage by placing pieces of lath on the trellis for them to rest upon. Guard against crowding or shading with more young wood than is necessary for next year's supply of fruit and the extension or furnishing of the trees. Finish stopping and tying the shoots. Continue syringing until the fruit commences to ripen, employing water that will not leave a stain upon the fruits. Inside borders should be well watered, also outside borders, this being necessary on account of the deficiency in the rainfall. A little spent manure placed on inside borders will keep the soil more evenly and longer moist, and by damping the mulching when it becomes dry, surface roots will be encouraged and the moisture evaporated favour the health of the foliage. In reducing the material on outside borders enough should be left to protect the roots and act as a light mulch.

**Succession Houses.**—Attend to the usual routine operations, and keep the trees healthy and vigorous by the timely application of water to the roots and foliage. Early and free ventilation is necessary to secure the solidification of the growth. Weakly trees, and those carrying heavy crops, should be assisted with liquid manure, mulching the borders with a little partially decayed lumpy manure. Allow a free growth of wood through the stoning process, but guard against retaining more shoots than can be tied to the trellis. If red spider appear apply an insecticide, and afterwards syringe forcibly. Brown scale usually attacks the young wood first, and if care is taken to remove it with an insecticide and a brush it may be kept from spreading to the foliage.

**Figs.**—*Earliest Forced Trees in Pots.*—When the very early varieties—Early Violet, St. John's, and Angélique—are cleared off their first crop, the trees should be well syringed, the top-dressing renewed, and copious supplies of liquid manure given to induce the second crop fruit to swell freely. If the fruit is very abundant it should be thinned, leaving a moderate crop only of the best fruits at the base of the growths, for it is necessary to secure a full first crop next season that the points of the shoots be well ripened, and not burdened with fruit in the current year. The watering at the roots will still require to be moderate for White Marseilles and Brown Turkey, now affording ripe fruit; but still afford the supplies needed to keep the foliage in good health, and damp available surfaces occasionally to prevent too arid a condition of the atmosphere. For the colouring and ripening process a free circulation of warm air is necessary, leaving the top ventilators open a little at night. This is essential to the fruit attaining perfection—high colour and quality. When the first crop of fruit is gathered commence syringing the trees twice a day, also watering copiously at the roots with weak guano or other form of liquid manure, with top-dressings of lumpy material, so as to encourage active feeders, and enable the trees to make a more vigorous second growth. If the fruit in the second crop show very abundantly they must be thinned, as before advised, so as not to overburden the trees, to the prejudice of next season's bearing.

**Planted Out Forced Trees.**—The trees in the house started at the new year are now giving indications of the first crop of Figs ripening and from that until the crop is perfected a little ventilation should be allowed constantly at the top of the house, and when the weather is

favourable a free circulation of warm, rather dry air must be afforded. Syringing must cease directly or slightly in advance of the fruit commencing to ripen, and, though moderate air moisture is essential to the health of the foliage, a superabundance of moisture about the house should be avoided. Let the fruit be perfectly ripe before gathering for home use; if it has to be packed it should be gathered a few days earlier, but never before it is nearly quite ripe at the base of the fruit. A good watering should be given when indications of ripening appear, which more particularly applies to trees with only limited space for the roots.

**Succession Houses.**—Attend to stopping the young shoots at the fifth or sixth leaf, but avoid overcrowding the growths, for the fruitfulness of Fig trees depends greatly on the exposure of the foliage and wood to plenty of light and air, and too close pinching and a superfluity of spurs is not desirable, as the finest fruit is borne on extensions. The successional growths also should be kept rather thin, allowing those only to remain that will be required to supplant the branches annually; cut out and maintain a proper successional supply of bearing parts. It is no use, however, striving to render gross trees fruitful by stopping and thinning, for nothing will do that but judicious root-pruning and limiting the rooting area, rendering it firm, so that the trees live thriftily. Attend to syringing the trees twice daily, and water abundantly at the roots as often as required; employ weak tepid liquid manure, especially where the borders are small, and add to the mulching so as to keep about an inch thickness of lumpy material on the border, into which the roots will spread, and they can then be fed to any extent.

**Cherry House.**—Early Rivers, Belle d'Orleans, Black Tartarian, and Governor Wood afford a supply of welcome and delicious fruit for some weeks. The fruit must be kept dry from the first indications of ripening, but the house should have atmospheric moisture furnished by damping the surface of the borders and paths occasionally. Admit air constantly, or condensation will take place, and moisture being deposited on the fruit, it will be ruined by cracking, and instead of having an agreeable be given an unpleasant flavour. The trees must not suffer from dryness at the roots, but the soil be kept in a moist condition, an examination being made periodically; and whenever a supply is needed, afford it thoroughly without delay. Tie in the shoots as they advance in growth, leaving no more than are necessary for furnishing the trellis regularly, allowing sufficient space for the spurs, and stop those not required for training in at about the fifth leaf, pinching subsequent growths to one leaf. Ventilate freely on all favourable occasions, and when the external conditions are unfavourable recourse must be had to the heating apparatus to ensure a circulation of warm, moderately dry air. Netting will be necessary over the ventilators to prevent the birds attacking the Cherries. Black aphides must be kept under by dipping the shoots or leaves in tobacco water.

**Strawberries in Pots.**—John Ruskin proves as prone to attacks of mildew as the Black Prince, and in many places this is a serious drawback to their cultivation. La Grosse Sucrée, therefore, still holds first place as the best first early forced Strawberry, and to succeed it none equal Auguste Nicaise, which is not only great in size, finely shapen, bright in colour, and a certain and great cropper, but the fruit is of excellent quality. Arrangements should be made to secure a succession of fruit, which is a matter of difficulty where forcing has to be carried on in vineries and Peach houses, for red spider is soon transmitted to the Vines or Peach trees from the Strawberry plants, which must be kept clean by regular syringing and due supplies of nourishment at the roots. Crops that are ripening may be retarded in various ways for several days in case an extra supply of fruit is required for particular occasions. Turning the fruits from the sun, shifting the plants to a north house, or removing them from under glass into an airy fruit room or other cool place after the fruits are fully ripe, are some of the expedients had recourse to. Much can be done to relieve fruit houses of Strawberry plants by accommodating as many as there are room for in cold pits or frames, where they will finish off well with judicious management, not forgetting to use protection over the lights on cold nights. All that were placed in cold pits some time ago for a late successional supply of fruit should have the flower spikes thinned out to the requisite number, keeping the plants well supplied with water, leaving room between them for a free circulation of air, and the foliage must be kept clear of the glass. Liquid manure should be given at every alternate watering to plants swelling their crops, taking care not to give it too strong, as that destroys the roots, and when cold it chills them, and causes the fruit to swell irregularly.

#### THE FLOWER GARDEN.

**Beds of Spring Flowers.**—A long spell of exceptionally hot and dry weather has greatly shortened the duration of the spring flowers generally, and it is not many of them that will interfere with the preparation of the beds for their summer occupants. In many cases the removal of the former may well be commenced at once, and this, though unsatisfactory in some respects, is not so in others. Usually the spring flowering plants that are reserved for propagating purposes or for future use are neglected during the month of June, but this year they ought to be taken in hand before summer bedding out commences. Some of the hardy plants are also very suitable for summer use, and these should be transplanted where this is necessary as early in May as possible.

**Ajuga reptans rubra.**—This is scarcely showy enough for the beds in summer, but is of good service during the winter. Nothing is more easily propagated. All that is necessary is to pull the old plants

to pieces, every little division with a few roots attached being dibbled in rather thickly in a cool moist position, and given water occasionally if the weather is dry till well established.

**Alyssum saxatile and Iberises.**—These are most showy spring flowering perennials and require almost identical treatment. The same plants if taken good care of are available for several seasons in succession, but it is always advisable to propagate a considerable number every summer, as they are rather slow in attaining a serviceable size. Much may be done in the way of splitting the old plants, every piece with a few roots attached being planted somewhat closely in rows 10 inches apart on a cool border. All old flowers and any fresh ones that form should be kept closely gathered from them, and without much further trouble a lot of strong spreading plants should be the result. Short rootless pieces or cuttings can be either dibbled out rather thickly and firmly at the foot of a north wall, though if enclosed by handlights and given the benefit of sandy soil they will strike more surely and quickly. They must not be allowed to suffer from want of water, and if not close up to a wall should be carefully shaded from bright sunshine.

**Arabises and Aubrietias.**—The variegated forms of the former if prevented flowering are very pretty, and quite good enough for summer bedding, as well as the winter decoration of beds. If there is no necessity to disturb them so much the better, but large old plants may well be lifted, divided freely, and replanted as an edging. Should the soil be at all dry, and very heavy rains will be needed to remoisten them, well water prior to replanting the Arabises, and again after they are planted, also shading them from fierce sunshine for a few days, branches of trees or evergreens answering well for the purpose. The ordinary flowering varieties of both Arabises and Aubrietias can be pulled to pieces freely and replanted somewhat thickly on good ground, taking care to well bury and fix the stems. This will be found a better plan than dividing the old plants when they are transferred to the beds in the autumn.

**Daisies.**—Already these plants have suffered badly from the heat and drought, and unless attended to soon many plants may be lost. The variegated form will be found a very effective edging plant for beds or borders in cool moist positions. Those growing solely for their flowers can be pulled to pieces and replanted somewhat closely in lines 6 inches or rather more apart, a cool position, such as the spaces among fruit trees and bushes, best suiting them. See that they do not become dry at the roots before they have time to take possession of their fresh quarters.

**Cerastium and Stachys lanata.**—These silvery foliaged plants are of good service during the summer as well as the winter, the former forming a neat edging for small beds, and the latter being most effective in a broad band surrounding large beds, or it may form the groundwork for groups in circles of Zonal Pelargoniums, Heliotropes and such like. The Cerastium may be pulled to pieces and replanted closely and deeply, much as Box edging is put out, and be kept trimmed into shape, while the Stachys can be very freely divided and replanted just clear of each other. Water the ground freely both before and after planting unless sufficient rains have fallen to well moisten the soil.

**Wallflowers.**—Hot sunshine quickly spoils these. Large old plants of the commoner forms, or such as can be readily raised from seed, are not worth keeping; but late-raised stocky plants if replanted among shrubs and other somewhat similar quarters and not again disturbed, would give a display of early bloom next spring. Now is the best time to sow seed. If the sowing is deferred later than May the chances are the plants obtained will be too small to be of any real service. Open shallow drills 6 inches apart on a well prepared border, water these gently, sow the seed somewhat thinly, and level over. Nothing but a long-continued drought ought to necessitate watering of these seed beds. If only a few dozen plants are required sow the seed in pans or boxes, and set these in a cool place. Double flowering varieties, other than the tall German strains, and which latter are raised from seed with the ordinary forms, are propagated by means of short cuttings taken or pulled off with a heel, and either dibbled in handlights set in a cool place, or else at the foot of a north wall or fence. Given the assistance of good light sandy soil, the cuttings being firmly fixed in this, and they will root more surely, and also transplant more readily than they will out of poor hard soil.

**Dactylis and Festuca.**—Dactylis glomerata variegata and Festuca glauca are effective for the beds either during the winter or summer, and ought to be very extensively grown where much bedding out has to be done. Both are suitable for edgings, the first named being the neatest in growth. If it is intended to increase the stock or to change the position this should be done soon. They will bear being pulled to pieces severely, but the divisions ought to be firmly and rather deeply replanted in fairly good moisture-holding soil, and watered occasionally till well established.

**Miscellaneous.**—Hepaticas transplant readily enough, and may also be freely divided at the present time. They succeed best in peaty soil and cool positions. Hellebores may also be removed from the flower beds, split if large, and be replanted among fruit trees or in other moderately cool positions. The Gentianellas do not move well, and thrive best where not exposed to fierce sun-line and are planted in strong soil. Now is the time to propagate by division. Saxifragas can be lifted, divided and replanted much as advised in the case of Daisies, and if sufficient seedling Primulas, Primroses, and Polyanthus are not already raised, the stock can be increased and improved by dividing and replanting on cool borders. All bulbous rooted plants that must of

necessity be moved from the beds to be relaid in moist garden soil till the foliage has ripened, when they may be again lifted and stored in boxes of sand. Many of the Conifers and evergreens when lifted will be found very dry at the roots. Soak the balls in tubs or tanks of water prior to re-planting.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### EXCESSIVE HONEY GATHERING.

THIS sometimes acts in a detrimental manner early in the year, causing hives to be unprofitable. Strong hives will have their combs well filled with brood and food for the young, and meanwhile the surplus honey can be stored in supers or extra divisions. This cannot be done with weak colonies, as all the bees are required to attend to the internal economy of the brood nest, and to the filling and sealing of the rest of the combs with honey necessary for breeding purposes. This prevents the extension of the brood chamber, almost putting an entire stop to the queen depositing eggs, consequently both queen and bees become crowded out, and the hive becomes unprofitable.

Between the extremes of having too little or too much honey the bee-keeper must act judiciously, as the one is as great a fault as the other when the remedy is neglected. In the one case the bees must be fed; in the other, honey-gorged combs should be removed, and full sheets of foundation supplied. With storifying hives, supplying an extra storey is an effective and simple remedy; but in no case should it be given without foundation, or drone combs will be built.

#### DRONE COMB.

Prime swarms, especially those having effete queens, are very liable to make a superabundance of drone comb, which also militates against profit. This should be watched and guarded against. The best remedy is to utilise nuclei with a youthful and fertile queen, which the clever bee-keeper will be sure to have in plenty early in the season to supersede aged queens. Queens are at their best when they at first begin laying, when there are sufficient bees to care for the eggs and larvæ, and they continue to be good for ten months or so after. Queens just a little before becoming useless show a remarkable degree of fecundity for a brief period. I do not argue that two-year-old queens are unprofitable, but place a number of queens in their first year and the same number of two and three-year-old ones side by side in equal condition, they will at an early time in the spring make it obvious to the merest tyro that the youthful queens are not only the most advanced, but that they are free from casualties that more aged queens are subject to, to the loss and dismay of the bee-keeper.

#### BEES AND THE WEATHER.

All the bee-keeper's hopes hang on fine weather, with a profusion of flowers, sunshine, and heat, with that amount of moisture that makes the earth fruitful and the atmosphere salubrious. At this period when bees are well supplied with stores and the weather is rather cold they remain within doors, there is no loss of bees, consequently the hives become quickly crowded with young ones, and the bees are all in the best of condition at the proper time to gather honey from the profusion of flowers. It is seldom that the honey season from any particular flower lasts longer than two weeks, and this is the reason that the largest yields of honey have been in seasons when the fine snaps of weather were fine but brief, and always after copious soft rains with heat. Heather blossom suffers greatly from excessive rainfalls. It is the evaporated moisture from the hills that sustains Heather, and makes it so rich in honey.

These remarks may appear to some to be superfluous, but the fact is many people are unaware that a long continuance of sunshine is inimical to the secretion of honey, far more so than a similar period of dull weather previous to the opening of the honeyed flowers. Beginners should study these things, and be able to understand bees and bee-keeping. When these items are understood and mastered bee-keeping becomes an easy matter and perplexity disappears.—A LANARKSHIRE BEE-KEEPER.

#### EARLY SWARMS OF BEES.

With reference to this subject on page 346 it may interest bee-keepers to know that Mr. Gibbon, Seaford Grange, Pershore, had a swarm on the 20th April. I heard of several others in the locality about the same time, but did not obtain the exact dates. Reference is made in the "Worcester Journal" of April 22nd, to many early swarms in various districts. I can only call to mind one swarm in April before, and that would be forty years ago.—J. HAM.

••All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Tea Tree (W. D. H.).**—This is *Lycium europæum*, and belongs to the natural order of Nightshades (*Solanaceæ*), and to the Linnæan order of Pentandria.

**Fungi in Mushroom Beds (T. R.).**—Your specimens arrived too late to have a thorough examination to enable us to give a full reply in this week's issue, but the matter shall be dealt with in an early number.

**Tomatoes Diseased (A. K. & Sons).**—The fruit sent is attacked by the destructive disease *Cladosporium lycopersici*, which causes the decay of the Tomatoes. An illustration and description of the fungus, also a method of eradication, were published in the *Journal of Horticulture* for May 19th, 1892, to which you may refer with advantage.

**Beeches Dying (H. F. C.).**—If the trees are not too far gone, a top-dressing of 9 inches of good soil would probably arrest decay, induce fresh growth, and in time render them healthy flourishing trees again. This is all that can be said without actual inspection. A practical man after examining the trees might be able to give useful advice.

**Vine Leaves Perforated (W. H.).**—The large, thick-textured, leathery Vine leaf has been eaten or perforated in its younger state by some insect, the appearance being that produced by the larva of the Apricot Moth (*Tortrix angustiorana*), which is also sometimes called the Vine Moth, as it occasionally finds its way into vineries and deposits its eggs on Vines, generally when they are starting into growth or later in the points of the shoots or bunches, where it spins a web and lives on the berries. There is nothing on the leaf and the damage is not recent, as the edges of the wound or perforation are healed over. It is hardly necessary to say—keep a keen eye on the Vines, especially the bunches.

**White Worms in Manure (G. W. C. R.).**—The "white worms" belong to the same order (*Oligochaeta*) as the earthworm—that is, they are true worms (*Annelida*). The eelworms belong to *Nematelmia*, and are not included in the *Annelida*, but with tapeworms in the *Scolecida*. "White worms" are often very abundant in partially decayed manure, especially that containing much vegetable matter, such as leaves, grass, vegetable refuse, hay, and straw, undergoing decomposition, and in soddened, sour soils. They chiefly subsist on dead or decaying vegetable matter, but they are supposed to injure the roots of plants by sucking the root-hairs, and in that way produce an unhealthy growth in the plants. Clover sickness, disease in Cucumbers, Tomatoes, and Vegetable Marrows have been attributed to "white worms" without sufficient reason; our observations tend to prove them mere scavengers, and not subsistent on living tissues, or only on those unhealthy and undergoing incipient decomposition. They soon die in drought, and quicklime destroys them.

**Basketing Orchids (A. L. M.).**—The following note, written by one who is an expert in the culture of Orchids, will answer your question:—The chief reason for using baskets for many Orchids is to provide those plants which have roots inclined to ramify beyond the limits of a pot, or are in need of more light and air and moisture, with a suitable medium for keeping them in a healthy state, besides affording the roots appropriate material to cling to, as well as for those of a pendant growth, such as *Dendrobium Wardianum*, and for suspending from the roof, where their beauty is better seen. There are some Orchids which refuse to grow in a pot or pan, but will thrive in a basket or upon a block. *Cattleya citrina* is one of these; *Cattleya Acklandiæ* and *Sophranitis grandiflora* are much healthier so treated. Other examples might be named, but where there are several plants of a genus it will be safest to start the plants under three different ways—by placing some in pots, others in baskets or on blocks. Experience will in time tell which presents the most suitable condition for their health. The operation of basketing imported plants is not more difficult than that of potting, because being already disentangled, and more or less injured in consequence, the object is to put the plants in the right way for recovery; therefore use reasonably small baskets, and fix the plants high in the centre of it, using two-thirds sphagnum to one of peat, placed carefully and rather firm round its base, adding

pieces of charcoal rather freely for large baskets, but in the case of small plants and small baskets little else besides charcoal and sphagnum will be necessary to give them a start. Such plants as Vandas, Saccoboliums, and Aërides require rather shallow baskets, Stanhopeas especially so, as they have a habit of sending their flower stems through the bottom and sides of the basket.

**Insects on Camellia Leaf** (*Somerset.*)—The cottony substance over the cylindrical patch or on the under side of the leaf acts as a covering to a number of small insects, which you may discover with an ordinary pocket lens to be brownish, and to have the shape of small scale, which they really are, and will soon spread over the plant. The insects, however, seldom become very numerous, as they are preyed on by other minute insects belonging to Hymenoptera, which are parasitic in the Camellia scale (*Aspidiotus* or *Dactylopius Camelliae*), but it should be extirpated by sponging the leaves without delay and so as to remove the cottony matter with a solution of softsoap, 4 ozs. to a gallon of water, to which a teaspoonful of petroleum may be added. The best way to prepare the mixture is to dissolve the softsoap in hot water, place in a 2 gallon stone bottle, add the petroleum, cork, and shake the bottle up and down, or to and fro for five minutes, pour about a pint into a vessel for use with a sponge, not using it at a temperature exceeding 100°, and so proceed. It is important that the petroleum be well mixed with the soapy solution.

**Zoospores** (*A. B.*)—The statement of a correspondent that the zoospores and fungi float in the air is probably incorrect, Griffiths notwithstanding. De Bary says:—"The spores of many Phycomycetes have the characteristics of autonomous motile cells, and are therefore named swarm spores, or zoospores, as having motion like animals. They are always formed endogenously by simultaneous division, and are liberated from the sporangium by a process of swelling. Their origin and their development, at least up to the period of germination, take place only under water; the species which produce them are inhabitants of the water, or at least their sporangia find their way into water for the purpose of forming the spores. . . . These movements commence in some species (*Saprolegnia*, *Pythium*, the *Chytrideæ*) inside the sporangium shortly before the liberation of the spores, and the cilia are by that time already formed; in other cases, as *Achylya* and *Cystopus*, the cilia and the movements make their appearance after the spores have entered the water. The motion under favourable circumstances only lasts a short time in the swarm spores of the fungi, sometimes only one or a few minutes."

**Gymnogramma chrysophylla Culture** (*A. S.*)—Your plant does not grow because the temperature has been too low. It requires a night temperature of not less than 55° in winter, and a moist atmosphere without the foliage being wetted. The plant is probably old; such plants never do so well as those which, from being very small, are liberally treated until they become specimens, after which they gradually decline. If you have now a small plant in, say, a 4½-inch pot, we should put it at once into an 8-inch pot, draining the pot to one-fourth its depth, and using a compost of sweet leaf mould one-half, turfy yellow loam one-half, and fibrous brown peat one-fourth, adding one-sixth of silver sand, the whole well mixed and broken with a spade, but not sifted. Pot rather deeply, but not so much as to cover the crown. The plant should be set in the lightest part of the house, have room on all sides, and be not more than 18 inches from the glass. The soil should be kept moist, but not wet, until the roots are working freely, and the temperature may range from 60° to 65° by night. By day it may be 70° without sun, and from 80° to 85° with it, shade being afforded from 9 A.M. to 4 P.M., when the sky is clear, but when cloudy do not shade at all. No shade will be needed from September to April. The plant must always have the soil moist, but no water should be given until it is really needed, then afford a supply sufficient to show itself through the bottom of the pot. If your plant grow as well as we expect, it will need a shift by the end of July, or at latest by the third week in August, so that the pot may be filled with roots before winter, as it will be in six weeks after potting if a 10-inch pot be given. From that time no more water should be given than is sufficient to prevent the soil becoming dry, and if a sufficiently moist atmosphere be maintained it will winter safely in a temperature of 60° at night, and occasionally as low as 55° or even 50°, but this degree must be seldom reached.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*G. P.*)—*Cerasus Padus*, the Bird Cherry, a native tree and plentiful in some districts. It is often called *Prunus Padus*, ornamental when flowering and is fragrant. (*J. B.*)—1, *Begonia metallica*; 2, *Alonsoa Warscewiczii*; 3, *Begonia ascotiensis*. (*J. J.*)—*Doronicum plantagineum excelsum*. (*L. B.*)—*Odontoglossum citrosum*. (*W. D. H.*)—*Lycium europæum*.

Bedding plants in variety.

#### FRUIT AND VEGETABLE FARMING.

MENTION is frequently made of more and more land being devoted to the cultivation of fruit and vegetables as a sign of progressive improvement, and it undoubtedly is so. But this extension of fruit and vegetable farming has a significance of far greater importance than the mere fact of planting so many more acres with such crops; it is part and parcel of a commercial revolution, which is swiftly bringing within the means of all classes of the community an abundant winter supply of the choicest fruits and vegetables of summer, either by means of evaporation, under which the water is simply driven out and all nutritive properties retained, or by canning or bottling, which involves some boiling and a total exclusion of air. Clearly this points to a profitable extension of this branch of farming on a very large scale, and the establishment of factories either at the farms or at convenient centres for obtaining an abundant home-grown supply. It is a matter of the utmost importance to farmers, which, if rightly turned to account, will enable them once more to make the land teem with plenty.

Judging from bottled fruit and vegetables now on sale this branch of the work is well understood, flavour, colour, and freshness being alike of remarkable excellence. Careful corking, sealing with melted resin, and the use of a thin metallic capsule, is the general method for air-exclusion. Some of the most delicious bottle Raspberries we have tasted were preserved by a lady in Derbyshire. She boils 3 lbs. of loaf sugar in a quart of water till it is clear; it is let cool, then 12 lbs. of the fruit is added, and the whole boiled together for two or three minutes, then put in warm bottles and tied down with bladder at once. She does Currants and Plums equally well, dividing the Plums and taking out the stones.

In the United States of America this has long been regarded as an important and highly remunerative industry. Here is a description of how they work, as given by Mr. Charles Whitehead:—A canning factory is provided with apparatus and machinery necessary for paring, coring, and stoning fruit. It is furnished with large tanks heated by steam for boiling fruit and vegetables. The process is as follows:—The fruit in the case of Apples, Peaches, and Pears is pared, cored, and washed in troughs in which there is clear water. It is then placed as tightly as possible into the cans. Plums are rapidly stoned by machinery and put closely into the cans. Then the cans are marked with the class of fruit in them, and are arranged in racks holding many dozens, placed upon trucks and carried to a tank of syrup from which each can is filled. At this juncture caps, or metal coverings, are soldered on by means of a clever machine which works most rapidly. A tiny hole is left in the centre of each cap. The truck with the cans is moved forward to a tank containing boiling water, in which the racks of cans lifted from the trucks are placed and kept, for spaces of time varying with the kind of fruit. It should be mentioned here that the hole left in the cap is so small that no water gets in and no syrup comes out. After the boiling the racks of cans are replaced on the truck and passed on to a station where the holes in the caps are stopped with solder. Again the cans are put into boiling water for a few minutes to destroy any germs within that might cause fermentation. They are then labelled and packed for delivery.

Syrup is added just in sufficient quantities to make the fruit pleasant to the taste, and not with any idea of preserving it. To Pears and Apples from 5 to 6 ozs. are given per quart can; to Peaches and Apricots from 3 to 4 ozs. per quart can; Gooseberries, Currants, Blackberries, Cherries, and Plums take from 6 to 7 ozs. per quart can.

With regard to vegetables the same process is adopted, but of course no sugar is added, and the cans are filled two-thirds full of water. The vegetables are prepared as for cooking, and they must be boiled much longer than fruits. Tomatoes are canned most extensively, and retain their fine flavour and agreeable qualities for long periods. Green Peas, French Beans, Asparagus, and young Carrots are peculiarly suited for this process.

As we explained last October, glass jars have very generally taken the place of tin cans in the United States. They vary in capacity from a pint to two quarts, have simply a neck flange, rubber ring, and screw top, which makes them quite airtight. Tin cans are regarded with suspicion from their tendency to render the preserved fruit or vegetables unwholesome by the acids which they contain acting upon the metal. Glass jars do not impart any flavour or taint to their contents if well washed, and are useable again and again. Fruit or vegetables are boiled till done, say ten minutes for any of the soft fruits, upwards to twenty minutes or two or three times as long for Apples and Pears.

#### WORK ON THE HOME FARM.

Lambs are being pushed on by trough feeding whether they are intended for sale in June or as hoggets at from twelve to fifteen months

old. They are compact, thrifty cross-breeds, which answer well under really good management, and are still profitable, but profits with lambs as well as everything else in farming become less every year under the persistent foreign competition, which has and will have to be met as best we can. Unquestionably the best way is to select well, breed well, feed well, and sell well. Breed your own stock, grow your own food, and be your own salesman. It is noteworthy that while sheep and cattle of the ordinary inferior market type fell steadily in price last year, the price of the best quality was well maintained. Much money has undoubtedly been made under the depression by those farmers who breed for quality to keep a large high class stock, to grow what corn was possible, to consume the whole of it, to supplement the home supply when necessary with purchased cheap foreign corn, avoiding cake bills altogether. One of the most prosperous men known to us in farming is a yeoman farmer who has kept most of his home farm in plough because of the demand for and high price of straw in his locality, owing to the fact of most of the farms being entirely in grass. He rears and feeds much good stock, hiring grass land when necessary, and is evidently prosperous because he is a keen man of business as well as a good farmer.

Since the advent of the locomotive steam thrashing machine large barns for corn thrashing have ceased to be a necessity. Many a barn have we turned into most healthy comfortable quarters for cattle. A barn may be made to serve all the purposes of a covered yard, it may do more, for with plenty of air shafts for ventilation a good substantial upper floor answers admirably for storing and cleaning corn. We mention this now the cows and store cattle are going out of yards, and attention is being given to any possibility of improved accommodation for another winter. Let this be seen to as soon as the manure is cleared out, and yards and buildings set in order before the hurry of haymaking and harvest is upon us. Should the weather prove cold and wet in late summer and autumn plenty of shelter may prove of material advantage for the live stock.

#### OUR LETTER BOX.

**Prickly Comfrey** (*H. F. C.*).—After giving this crop a fair trial, we found it practically worthless in comparison with such other fodder crops as Rye, Rye Grass, mixed seeds, Sainfoin, Red and White Clover, Trifolium incarnatum, and Lucerne, so that our culture of it never got beyond a trial. Most or all of the green crops mentioned should answer with you. Do not forget our advice to grow as much Green Maize as your cattle can consume before frost sets in. Sow early in June, and have a sharp outlook kept for rooks, or they will have all the seed.

**Bottling Fruit and Vegetables** (*S. J. A.*).—The glass jars mentioned in our article on this subject on October 27th, 1892, are those in use in the United States of America, where they now have preference to the tin cans long used in that country. They have a rubber ring or flange, and screw top for the exclusion of air. We cannot say where they can be had in this country, but have no doubt a prompt supply will be forthcoming in response to any demand for them from any large dealers in such ware. It is obvious that vegetables preserved in cans or glass jars require more boiling than the softer fruits. Evaporated fruit and vegetables simply have the water driven off, and are preserved in a dry state. Canned or bottled fruit and vegetables are boiled and preserved in a cooked condition. That this process is well understood in this country we are convinced, from the excellent examples of bottle fruits now to be had from provision merchants at a very low price. We have recently had at table excellent Plums, Damsons, Raspberries, and Currants; also what are sold as Yorkshire Marrowfat Peas, which were delicious both in tenderness and flavour. Such vegetables are indeed a boon in winter, and the price (8d. per bottle) appears to us to be reasonable. They should be preserved when in the best condition for current use. This subject is more fully dealt with in our home farm article this week.

#### REMARKS.

23rd.—Almost cloudless throughout.  
 24th.—Almost cloudless throughout.  
 25th.—Bright sunshine all day.  
 26th.—Cloudless till late evening.  
 27th.—Overcast till 10 A.M.; bright sun after 11 A.M.; cloudless afternoon and evening.  
 28th.—Overcast early; bright sunshine from 9 A.M. to 3 P.M., when it clouded over and remained overcast.  
 29th.—Overcast till 8.30 A.M., bright sunshine after, occasional cloud in afternoon, and spots of rain between 9 and 10 P.M.  
 Another warm, dry, and rainless week with very little cloud.—G. J. SYMONS.

"ALL Roads lead to Earl's Court." This is what we read on large posters displayed on buildings in London and surrounding districts. It is true enough if only the right turns are taken, and it is equally true that all the inhabitants of the horticultural world who can do so will find their way to the Gardening and Forestry Exhibition which is indicated in the above geographical expression. The quickest way, no doubt, to persons who find themselves in the city or its confines is the underground railway, and once on the track there is no danger of wrong turnings being taken to Earl's Court Station, which adjoins the Exhibition, while the West Brompton Station is very near it. After learning somewhat of the way to a particular centre, the next thing the public, who are interested, wish to know is of what there is to be seen on arrival. This opens up a gigantic question, for no other term adequately indicates the character of the forthcoming attractions as suggested by the nature of the preparations now advancing to completion. It is not too much to say that plenty will be found to afford instruction and give delight to all who wish to learn something on gardening and forestry, and find recreation of the most wholesome kind amid beautiful surrounding—*plus*, for those who desire the change, scenes in French history and amusements on the one hand, and what may be termed a water carnival on the other, such as has not been previously seen in this country if in any other.

Foremost, however, is the Gardening and Forestry Exhibition. On the preparation of this much thought has been expended and skill displayed. The grounds have been remodelled, the main or central portion presenting a more park-like appearance than last year, while nooks and corners have been utilised in representations of small gardens, and plans carried out that suggest how many a dingy forecourt—and there are far too many attached to the homes of the people—may be rendered pleasing by the exercise of taste, such as is indicated in the appropriate object lessons of Mr. Milner and his coadjutors. These grounds, with their several attractive features, will form a rendezvous for the million, whose lives are mainly spent in office, shop, or factory, and who must, when their duties are over, have "somewhere to go." Where better can they go than into a garden with trees and flowers around them, brilliantly illuminated, and the best of music provided to drive dull care away? As a nation we are said to take our pleasures sadly, and it is sad enough to think of the old methods of crowding in drinkshops and stifling buildings on beautiful summer evenings—a practice not yet obsolete, but happily becoming less popular in proportion as counter attractions of a wholesome nature are provided. The most effectual of these have been the parks and gardens that are established and so well maintained around the metropolis and other populous centres. It is impossible to over-estimate the good that these have done to many in many ways; but when the shades of evening fall the people are not rung to bed by the curfew bell, and instead of lights being put out, night, so to say, can be turned into day as long as is needed by the agency of electricity. This was so last year at Earl's Court, where thousands of persons assembled, and there was a gratifying absence of anything that could offend, but all was orderly, and the multitudes represented the best side of the British community; so it will be again this

year, and as outdoor pleasures are becoming more and more popular it may be expected that still greater numbers will find their way to the illuminated pleasure grounds during the present season.

Though the great bulk of visitors will be in search of enjoyment and recreation, those who need it may also find instruction in gardening and forestry. Exhibitions of plants, flowers, and fruit, as well as of wood and its uses, are always instructive to those who are disposed to read the lessons conveyed; and it is reasonable to suppose, in fact practically certain, that not a few persons who are brought into contact with the work of experts in cultivation and handicrafts have their interest excited, and themselves become students in the hope of becoming practitioners in turn as opportunities occur, or are made, for earnest people make them. The object of the promoters of the Gardening and Forestry Exhibition is to afford pleasure with instruction, and it is because the combination is regarded as good that it is recognised by the highest in the land, and receives the active patronage of members of the Royal family, distinguished ecclesiastics, and leaders in thought and education. They believe that wholesome recreation and intellectual enjoyment are worthy of encouragement, or they would take no lead or part in their promotion.

The Exhibition is as yet in its infancy—necessarily incomplete, but growing. The great covered garden that was somewhat of a tropical mixture last year will at the opening on the 13th inst. present a very different and at the same time a brilliant appearance. Rhododendrons will predominate. The side banks and beds have been planted with compact floriferous shrubs by Messrs. William Paul & Son, Waltham Cross, and H. Lane & Son, Berkhamsted. These with their myriads of trusses in varied colours will make a show in themselves, and will form a background and foil to other plants that will be introduced as the season advances. The central portion of the garden will contain beds of Roses and other flowers, forming altogether a rich floral feast. In the grounds beds and borders are being planted by nurserymen with various shrubs, and walls are being covered with climbers. Messrs. Cheal and Son have planted a miniature orchard, also a garden of fruit trees of varied shapes and forms, with vegetables growing between them. The fruit arch and diamond fruit fences are also represented, but the prolonged dry weather has militated against the satisfactory growth of the trees, and some of them can only recover slowly; and the same may be said of trees generally which have been planted late under unfavourable conditions. There is a toy-like example of forest planting, representative of trees and shrubs appropriate to sandy, chalky, and clayey soils. It may cause passing interest, but is only as was graphically inscribed by an expert, "Forestry on a postage stamp after all."

The exhibition of woods is in the annexe on the left of the entrance, and whether the small beginning will grow to good dimensions time alone can tell. Several specimens have, however, been got together, and doubtless more will follow. One of the famous Burnham Beeches has been brought and planted by Mr. H. Turner, a giant trunk and quaint relic of antiquity 800 years old. Wooden water pipes of ancient London are also on view, tree trunks bored through and have been no doubt buried for centuries. There are also more modern trees, notably examples from Highclere, the Earl of Carnarvon's, namely the butt of a Douglas Fir sixty years old, the cubic contents of the tree 169 feet; *Pinus strobus*, 100 years old, cubic contents 110 feet; *Pinus Laricio*, sixty years, contents 111 feet and *Abies Menziesi*, forty-five years old, cubic contents 80 feet, with planed boards from the same trees. There are also specimens of wood and insects in cases, to which additions will doubtless be made. The original specimen of Cherry grafting that was illustrated in the *Journal of Horticulture*, page 343, April 27th, is on view showing the wood of the scion attached about twenty years ago in process of decay, but the surrounding growth of stock and scion bright

and healthy. Not far from the entrance the grotto and fernery, in course of construction, will form a cool retreat for visitors. Here, too, is a fine scenic representation of Mr. Leopold de Rothschild's beautiful garden at Ascott, the same as depicted in the *Journal of Horticulture*, February 5th, 1891, the colour and distances being admirably rendered.

As auxiliaries of the Exhibition, Old Paris—the Rue St. Antoine and the Bastille, a realistic piece of work, produced at a cost of £16,000, will be sure to prove attractive; and not less so will the wonderful "water show" of Captain Boyton, the preparations for which are of an extraordinary nature; but these are side issues, remarkable though they be. Returning to the pleasure grounds, we had omitted to say that the Eldystone Lighthouse is nearly completed, and visitors will not omit to see it, nor will they the great scenic representations of the wooded hills and vales of Surrey on the one hand, and the Lakes of Killarney on the other.

Such are, in brief, the permanent attractions, and then follow the periodical horticultural exhibitions. The nature and scope of these have been indicated by advertisements. Equalling, as they may be expected to do, the displays of last year, they will form a magnetic force to many. In connection with the whole great undertaking at Earl's Court the endeavour is to do all things well, in the hope that at the end of the season millions of people will have visited the Exhibition, and have no fault to find. Mr. H. E. Milner is the chief, and Chairman of the Exhibition Committee; Mr. George Cadell Vice-Chairman, Forestry Section; Mr. Harry Turner Vice-Chairman, Horticultural Department; Mr. G. A. Loveday, Secretary, and Mr. Richard Dean Manager of Shows.

### THE GLORIES OF MAY.

MAY is essentially a hybrid month, intervening exquisitely between spring and summer, and partaking of the fairest characteristics of both. It is one of the most picturesque seasons of the year. Perhaps its greatest glories are its wayside and woodland flowers. The Gorse, called in Scotland the Whin and in Ireland the Furze, is at present a veritable picture of perfect beauty; and we do not marvel that it drew forth, when he beheld it for the first time, the rapturous admiration of the great Linnæus. Nor less impressive is the splendour of the golden Broom, which seems to set our Scottish glens on fire in many places at this period of the year. Wild Violets are growing luxuriantly on every grassy bank; the Wood Sorrel (*Oxalis acetosella*) is gleaming everywhere beneath the shadows of the trees. This is one of the loveliest, and also one of the least celebrated of sylvan flowers; and yet surely it is as worthy of being sung as the "Daisy" of Burns or James Montgomery. I have endeavoured to do it justice in one of my "Poems of Nature and Life," from which I give my readers the following quotation, unworthy though it be:—

- "Exquisite floweret of the vernal hour,  
Whose tender sweetness steals upon our gaze  
When the wild glory of the glittering shower  
Has faded in the sun's luxuriant rays;  
"Meekest of all the blooms that God has given  
To star this marvellous mystery of earth  
With gentle gleams of that ideal Heaven  
Where Love the beautiful found radiant birth;  
"Even one so insignificant as thou  
May bring high thoughts to men of reverent mind;  
For that meek loveliness thou wearest now  
Flowed from an art our efforts fail to find."

I may state that the Wood Sorrel was a special favourite of my friend Matthew Arnold, who, when acknowledging very kindly and appreciatively my poem upon the subject, told me he was particularly fond of the flower. In one of his many interesting letters he said of another of its vernal predecessors, "I do not know that I have ever mentioned the Snowdrop in my verses; but I have been planting it about my shrubberies, and admire it greatly." He had done so nevertheless, as I afterwards reminded him, in his intensely classical poem of "Tristram and Iseult." Arnold was essentially, like his great teacher William Wordsworth, a poet of Nature; and such genuine inspirations as his "Sohrab and Rustum" (the nearest approximation to the spirit of Homer discoverable in our literature), "Thyrsis," the "Scholar Gipsy," and the sublime masterpiece entitled "Empedocles on Etna" are full of Nature's

own ethereal mystery, sweetness, and light. Like Tennyson, he had two predominating passions—the love of solitude and the love of flowers. To escape from the multitudinous roar of the modern Babylon to his tranquillising garden at Pains Hill, in Surrey, was to him an ineffable delight. There I usually found the serene singer of culture and poet of peace earnestly engaged in horticultural operations.

Not less beautiful than the flowers of the forests and the fields are those of the garden in this gracious month of May. The various and varied fruit trees, especially those of the Apple and Cherry, the latter of which looks as if it had been suddenly whitened with a shower of snow, are at present absolute marvels of loveliness, which no artist, however greatly gifted, could adequately depict. There is something in the mystic perfection of Nature which eludes the grasp and transcends the range of Art. Next to these transitory splendours of the trees I would place for floral impressiveness two borders of Violas, natives of Rothesay, in the fair island of Bute, which appear from their luxuriance to have found in a region more visited by the east wind a congenial home. Among the finest of these are Henry M. Stanley, Ravenswood, Mary Queen of Scots, the Lemon Queen, Abercorn Beauty, Mauve Queen, and Edina, of which the last-mentioned somewhat resembles the older and better known Countess of Kintore.

Since I sent my last contribution to this Journal rain has come in the part of Scotland from whence I write, falling like life, blossoming into beauty upon the place beneath. It is "twice blessed," for it beautifies the flowers upon which it descends, and is itself made fragrant by them in return. Its influence upon the Rose trees has been especially benignant, and many of them are already prolific of buds, and give promise of perfect bloom.—DAVID R. WILLIAMSON.

### BEDDING NOTES.

OWING to the earliness of the season bedding out will no doubt be in progress shortly throughout the country, for there is every indication that it may this year be safely begun at this early date. Although the thermometer in this district frequently touches the freezing point, neither Potatoes, Vegetable Marrows, or Pelargoniums in the open air appear to be injured in the least. This, I think, shows that although such low night temperatures are recorded they only remain at the lowest point for a very short time, and after the long spell of dry hot weather and freedom from severe frosts which we have lately experienced we may reasonably anticipate weather as favourable for the well-being of bedding plants as that which we generally have in June. Spring bedding is with us now (May 6th) in full beauty; even such things as *Silene pendula*, which is generally the latest to flower of all plants used for the purpose, is at its best, and it would be difficult to find a more beautiful plant for growing in masses during seasons like the present one. We have two long beds filled with it, edged with *Cerastium tomentosum*, which find a host of admirers.

Where spring bedding is not carried out the whole of the beds will now be in readiness for planting the edgings of Sedums and Echeverias, other comparatively hardy plants being already planted, and a definite plan of arrangement having been prepared the work may be pushed on expeditiously, planting such as Pelargoniums, Fuchsias, Calceolarias, and Lobelias, reserving spaces for the more tender kinds like Coleus, Iresine, Alternanthera, and Heliotrope. These may be planted a couple of weeks later. Few gardeners of the present day are, however, able to work on these lines, for spring bedding has of late become so general as to necessitate a totally different method of procedure. It is desirable when once the display is begun in April to keep it up with as little break as possible till the end of September. To do this each bed must be left till its beauty is on the wane, be then cleared and replanted with good plants ready at hand. Beds which are now occupied by Wallflowers, Myosotis, *Silene*, Aubrietias, and Daisies will afford good positions for Calceolarias, Zonal and Ivy-leaved Pelargoniums, Begonias and Marguerites. All of these beds having been well manured previous to the autumn planting will require no additions of soil or manure now, but should have the soil deeply dug and thoroughly separated, not forgetting to tread very firmly before planting if the soil is light.

Beds in which Violas are now in full flower only require an edging of Sedum, Aubrietia, or Arabis, to be replaced by one of Lobelia, Pyrethrum, Iresine, or Mesembryanthemum. Violas rooted in August last are now flowering freely, and will continue to do so all through the season if abundance of water is given. These beds may be made still more effective if dotted with tall plants of Heliotrope, Fuchsias, or Abutilons, disposing these dot plants from 2 to 3 feet apart according to their size. This method of planting is especially suited for large beds, those of only

moderate dimensions being the most effective when used as a means of supplying a mass of bright colour. I always employ a good number of two-year-old plants of both Pansies and Violas; these flower very early in the spring, and are now a perfect mass of flower, but will not continue satisfactory throughout the summer. These are provided for in the following way:—A number of Pelargoniums are potted, and have their flower buds removed till the middle of June. By the first week in July the beauty of the Pansies is on the wane; they are then removed, and their places occupied by these prepared Pelargoniums, which are by that time covered with flower buds just ready to open, and with careful planting and watering a good show is obtained almost immediately. A number of Stocks and Asters are also prepared by planting 9 inches apart in nursery beds; these in time take the place of the two-year-old Violas, and create a seasonable and beautiful display late in summer.

Before commencing to set out bedding plants in their summer quarters it is important to see that all have been thoroughly hardened, for it will assuredly prevent much future disappointment. To see Pelargonium leaves turning a bronzy brown colour after planting is a sure indication that the hardening process has not been completed. When the plants are kept in pits or frames up till the time of planting out the lights should be entirely removed for at least a week previous to planting, because it is quite as necessary for them to be inured to sunshine as well as to comparative cold. If, therefore, by any mischance plants have had the lights kept partially over them till they are wanted for planting, Yew, Spruce, or Laurel branches disposed among them for a few days will effectually prevent them from being injured by sunshine during the day or cold at night. It is well to be prepared for such contingencies, but better still to provide against them by exercising care and judgment to have all plants thoroughly hardened by the time they are required.

Should the dry weather continue the work of bedding will unfortunately be more laborious than usual, as regular watering will be absolutely necessary for the well-being of many plants. Even where plenty of water and hose are at command much valuable time is taken up with the work, but where these conveniences are not provided the task is an Herculean one during a season like the present. Much may be done in such cases by obtaining water carts and garden engines of one of the many improved types now advertised, which are labour-saving machines of immense benefit to both employers and gardeners, for it is only by seeing that the plants are thoroughly moist at the roots when planted, and by watering continually after planting till they are established, that the occupants of the flower garden can be kept in a satisfactory condition during seasons of prolonged drought.—H. DUNKIN, *Castle Gardens, Warwick.*

### ANTIPODEAN APPLES AND THE R.H.S. NORTHERN SPY AS A STOCK.

SOME time since I saw in one of your publications an article from the Curator of the Chiswick Gardens, asking for cuttings or plants of any new or rare Apples for the Royal Horticultural Society. I went to a good deal of trouble and some expense in obtaining cuttings of Australian and New Zealand seedlings that are growing and fruiting in this district. I obtained something like three dozen varieties; I carefully packed them and sent them by post to Mr. Barron eight months since, along with a letter. I have never heard anything of their arrival, or received any communication from the Society on the subject. My object in writing this is to show how little anything of the kind is appreciated, and to prevent others, like myself, going to trouble or expense in trying to confer a benefit. Many of the varieties I sent were great improvements on older sorts. Seeing that Bismarck Apple is becoming so popular (and as I was the first to introduce it into England), I thought I should do something further to add to the popularity of colonial-raised seedlings.

Whilst on the subject of Apples, I see by an article in your paper that the Northern Spy does not fruit well or early in England; the same complaint was made here until we commenced to grow it on its own roots. We now find it fruits much earlier, and bears larger and finer crops. I have some trees only three or four years old from the root grafts now bearing beautiful fruit. If "R. M., Newbury," will write to me and send his address I will send him a few young trees grown on their own roots. On account of the woolly aphis attacking the roots of Apple trees so severely here, we use the Northern Spy wholly as a stock, and from my long experience I have no hesitation in saying that, apart from its blight-resisting properties, it is the best stock in the world on which to work Apples. There is a small fortune for any nurseryman who first makes it a speciality as a stock for Apples. I have

never yet met with a variety that does not do well on it, from the Siberian Crab to the Blenheim Pippin. The union is always perfect and the growth good. I have not much faith in my hint being taken; the British public are so wedded to old notions that generally the rest of the world have adapted any new idea before they awake to its utility.—W. J. PALMER, *The Nurseries, Carleton Gore Road, Auckland, New Zealand.*

[Mr. Barron informs us that the grafts referred to never reached him, and that letters are answered in the Secretary's office in Victoria Street. He received grafts from another Antipodean source, but they arrived in bad condition, some packed in crushed charcoal being dead on arrival. We have heard from other sources of the value of the Northern Spy as a stock, and it is noticeable that trees of this variety are singularly free from insects.]

### THE LARCH DISEASE.

THIS subject, introduced by Mr. Williams (page 292), is opportune, and also interesting to those with experience of the disease, which, I am sorry to say, is increasing in these parts. The exceptionally severe weather experienced at what I call an unseasonable period has much to do with the spread of the disease. Take for instance the 7° of frost registered here on the morning of Whit-Sunday, May 17th, 1891. At that time the trees had made 2 inches of new growth. In one plantation alone 15,000 trees were injured, many of them being 15 feet high. Such fluctuations of temperature as this must have an injurious effect upon the trees, other than the destroying of the season's growth. Unfortunately the spread of the dreaded Larch disease is not the only ill caused by adverse weather. The trees are left in such a weakened state that they so easily fall a prey to the attack of insect pests.

The months of February, March, and April last year being so exceptionally dry, directly new growth commenced on the trees injured by frost the previous year it was attacked heavily by the sheath caterpillar of the *Colcophora laricella* moth. Until the shoots were fully developed these caterpillars voraciously devoured the tender leaves, giving the trees a bleached appearance. On a neighbouring estate a portion of a plantation of Larch of 5 acres was slightly injured also by the frost occurring on the date named, but the same trees almost escaped the caterpillar plague last year. However, this year the caterpillar has made sad havoc of those in the plantation named that escaped last year. The weakest trees were first attacked, the ravages gradually extending over three parts of the plantation and slightly affecting some in an adjoining wood, these latter trees being fully 30 feet high. As in our case the trees are growing in a thin bed of soil overlaying a chalk foundation. Until the trees received the check by the frost named a diseased tree was an exception, but now 75 per cent. are affected. The disease appears generally in that part of the tree which is three or four years old, the formative fluid or cambium being larger in that part than in any other, and hence its susceptibility to adverse climatic influence. My opinion also is that the chalk foundation has much to do with the presence of the disease. This mineral has a decided influence on the progress of the trees, and in some cases increases the disease.

We scarcely ever find the disease on trees growing in stiff soil intermixed with flint stones as is present in some parts of the estate, not even in the same plantation where the trees were so much affected by the frost of 1891. The soil in this plantation is so variable that both kinds are found within a short space of each other. However, Larch timber growing wholly in chalk in this neighbourhood is considered to be of superior quality up to at least sixty years old where the trees escaped disease in their earlier stages of growth. The grain of the wood is of that rich colour so pleasing to timber merchants as compared to that grown in soil opposite in character—sand, for instance.

Some persons attribute the Larch disease wholly to a wet and ungenial soil, owing to its want of drainage. I do not dispute that such conditions are favourable to disease, but as to being wholly the case, I am convinced this is a fallacy. On this estate it is not possible to find a wet piece of land. I mean by wet, where water collects on the surface, refusing to percolate for a time. Throughout the whole of the estate chalk is the foundation, varying in the distance from the surface as much as 19 feet in some parts, and as little as 4 inches in others. I find where trees from 3 feet high up to 12 feet receive a check in their growth by frost or insect pests they are more liable to disease. The disease does not in all cases kill the trees, as close here some planted twenty-two years since, and now 40 feet high, were attacked about 6 feet from the ground, but have apparently grown out of the difficulty. It does not follow either that all Larch planted on chalk subsoil necessarily

become diseased. One part of this estate—about 3 acres—on a sharp slope facing north was planted fourteen years since; here but a few inches of soil was found overlaying the chalk. Not a single tree as yet shows the slightest sign of disease; many of them are now 30 feet high. In that particular spot the air is dry, if cold; spring frost does not affect the growth; and no matter how cold the weather may be, if the atmosphere is fairly dry and there is no stagnation of water at the roots, this northern exposed situation is favourable to Larch. I do not find that the Larch bug (*Chermes laricis*) in any way affects the trees, either in growth or disease.

Where the disease is present on trees that have not received a check, either by spring frost or insect ravages, my experience leads me to say it is owing in some way to the chalk foundation, as I cannot find any on trees that are growing in stiff soil in the same plantation. It is a common occurrence here to find trees the leaders of which make 3 feet of growth in one season, and one with a 4 foot shoot has been seen. This latter was on a tree growing in chalk on a northern slope. I also find that more time is required for trees to become well established when planted on a site where but a few inches of soil overlays the chalk than where the surface soil is heavy in character.

From the fact of *Abies Douglasi* growing well with Mr. Williams I should judge that the soil is inclined to be sandy. Here in the natural soil this tree absolutely refuses to live, let alone flourish as a timber tree. We have now a few small trees in the shrubberies, but it is necessary to have their roots in a compost of peat and decayed leaves, if the natural lime-impregnated soil comes in contact with them the colour of the trees change quickly, and they eventually turn quite yellow, and ultimately die. We have had at least a dozen trees, in height ranging from 6 feet to 10 feet, go off entirely. It cannot be aught else beside the total unsuitability of the soil that compels this species to behave thus. The ordinary Spruce Fir makes rapid growth here. I am informed up to forty years of age it succeeds really well, after that the trees deteriorate. I cut down a few years since several fine specimens of *Abies excelsa monstrosa* seventy years old, quite firm in the wood, but the branches exhibited distinct signs of decay.—E. MOLYNEUX, *Swanmore Park, Hants.*

## WINGLESS INSECTS OF THE FLOWER GARDEN.

THE subject of insects is not wholly "concluded," as inadvertently stated recently, for we have yet to briefly notice an important and very distinct group of wingless insects which are on the boundary line, forming a kind of link between these and the Crustaceous order. At one time, indeed, naturalists classed them with lobsters and crayfish, but modern science regards them as true insects, though they have no chrysalis state. There is a larval, or imperfect condition, in which changes of skin occur, and of appearance also, but the creature never ceases to eat during its progress to the adult stage. Our first division of these is the Myriapods, a general name which says too much, for no specimens have a thousand legs, even in the millepede division, the insects of which have, in some places, the popular name of "maggy-many-feet;" certainly counting them is not easy, owing to the quick movements of most species and the closeness of the segments. In the centipede division, however, some species have about a hundred legs, but most have a less number than that. Tough and slim-bodied, some of the centipedes have been mistaken for the larvæ of a troublesome beetle, and in consequence called "wireworms," the true wireworms being the progeny of one of the species of *Elatér*. As foes to farmers and gardeners they are far more terrible than any of the Myriapods.

Regarded from the horticulturist's point of view, the jaws of these insects are much more important than their legs; by them they are divided into two sections, one of which is no doubt capable of doing much mischief to plants, and the other but seldom feeds upon vegetables. Besides these leading groups, there is one small division of Myriapods, where the mouth is furnished with a sucking apparatus, and has no jaws. The Julidæ, which are the millepedes of our gardens, hauntings of roots, bulbs, and the crowns or underground stems of plants, have jaws of the usual kind, well suited for biting vegetable substances, though it has been repeatedly proved by observation that they vary their diet by sometimes eating soft insects and molluscs, such as slugs or little snails. But the Scolopendridæ have an apparatus quite different, which affords proof that they are of carnivorous habit. Instead of the jaws or mandibles, these, the centipedes, have a sort of nipper more like a leg than a jaw, which has a sharp point and a tube that is connected with a poison gland. Hence it is that the bite of the large centipedes of hot countries is painful or even dangerous, and even the species of our own land are noticed to kill rapidly any insects

they may seize. That the centipedes generally have an evil repute amongst gardeners is a positive fact, but the evidence of structure and habit goes to prove, that though they are often found upon the injured roots of plants, their presence is beneficial, since they come to prey upon the insects that have caused the damage. Some think that even when a centipede is found coiled up within a Plum or Apricot, having entered by the stalk, it is only in the fruit to devour aphides or mites that have previously entered owing to commencing decay. Curtis satisfactorily vindicated a species of centipedes from the accusation of being concerned in the Potato disease. Myriads of them did occur amongst the infected tubers in many places, but they had neither caused nor aggravated the disease.

The millepedes, however, do feed upon some of our root crops, and in our beds and borders, also in conservatories, they attack bulbs, the stems of some herbaceous plants, and roots, especially those of a succulent nature. Like the woodlice, they show strong partiality for Orchids, eating eagerly the young fibrils of the roots. Frequently the plump millepede *Glomeris limbata* is taken for the Armadillo woodlouse, and the two have a marked resemblance, but the woodlouse has a harder shell and longer antennæ. Exotic specimens of these millepedes occasionally arrive in company with plants from Asia and Africa. When they infest hothouses it is a good plan to set traps for these, similar to those for woodlice, such as Apples and Potatoes with holes scooped in them, or small pots filled with partly dried horse droppings. Both offer much attraction to the insects, and scores may be captured and easily destroyed by shaking out the contents of the traps into boiling water.

The snake millepedes offer a contrast to their stout brethren above mentioned, and as a matter of course they are more clever at concealing themselves; few gardeners notice them in the juvenile stage, though they are not so slim then, and start life with only half a dozen legs. This moderate allowance of limbs is soon increased, for every new segment has another pair, till a total is reached of above a hundred. Owing to the form of millepedes they cannot put forth the muscular power many insects can, but they show much dexterity in enlarging any small holes they may find in hard tubers or stems, and they will manage to work into the interior of large pulpy roots, while the small fibres much delight them. *Julus terrestris* is our largest British species; it is upwards of an inch in length when full grown, and is very like the next species in size, called *J. londinensis*, from its frequent occurrence in London gardens; but the former species has a little spike at the tail, and longer antennæ than its relative. Another species, *J. latistriatus*, is inclined to be sociable, and small parties of them appear unexpectedly sometimes when ground is being turned over. Some of the Juli haunt moss and decaying stumps of trees. Possibly, to some people, the name given to another well-known species, *J. pulchellus*, may seem inapplicable; they may not connect the idea of beauty with a millepede. Yet it has not an objectionable appearance when examined by a magnifier, the slender and pale body being adorned by a double row of bright crimson spots. Many gardeners report this as one of the specially injurious snake millepedes, attacking plants in pots and in borders, often selecting those of the Liliaceous order; it rivals the *Eucharis* mite in damaging that favourite flower.

A connecting link between millepedes and centipedes is in the genus *Polydesmus*. These insects are flat-backed, and have the segments granulated, also they have a harder texture than the Juli, but the limbs break off with a slight touch. Our largest species is *P. complanatus*, which grows nearly to the length of an inch, and is of a whitish blue colour, frequently, like the Juli, family or friendly parties surround the roots of choice plants, rousing the ire of the cultivator. Pansies, Auriculas, and Anemones are injured by them, the cause of the mischief being sometimes unknown even if suspected. It is difficult to kill the insect without also risking farther injury to the plants. When millepedes lurk in flower-pots watering with clear lime and soot water is found to be of some use, also a very weak solution of carbolic acid has been tried, not more than ten or twelve drops to a gallon of water. Some have commended hellebore solution, strength 2 ozs. to a gallon; this certainly does no harm to plants, and will destroy many other insects besides millipedes which infest roots and stocks.—ENTOMOLOGIST.

## TOMATO GROWING.

[By Mr. E. D. SMITH: read at a meeting of the Sheffield Chrysanthemum Society.]

(Concluded from page 360.)

### WATERING.

It is possible by judicious attention to sprinkling the plants and soil daily for a time in bright weather to retain the soil moist without watering too freely. The supplying of water generally must be pro-

gressive. Too much in the early stages of growth hinders the formation of roots by souring the soil; too little when the plants attain to a fruiting state causes the flowers to drop. The rule to follow is water carefully until established. When fruiting commences and heavy crops draw upon the plants' resources water abundantly. Do not wait at any time for the plants to flag, but anticipate their requirements. With rapid evaporation in hot sunny weather, and the soil fully occupied with roots, water is needed often twice a day, each time reaching the most distant rootlet. Half supplies may keep the plants in existence, but they will not promote their vigour and productiveness.

#### TRAINING.

The Tomato is naturally a wild grower and needs a certain amount of restriction. There is no need to dwell on the disadvantages of crowded growth. If too rank it will produce nothing, or at the best poor fruit. The energy and vigour of the plants are wasted unless each branch has room to extend with space laterally so that a due amount of light and air can reach every leaf. The principles of training the Tomato are these: Each branch will produce fruit providing it is allowed space on each side of not less than one foot from the adjoining branches. There are constantly appearing from the axils of the principal leaves on every main branch a succession of side shoots which, if allowed to grow, are the means of choking the plants with useless growth. These need constant suppression soon after their appearance, when they can be easily rubbed out. After attaining to more than an inch or two in length they must be cut out. The most satisfactory plants, as a rule, are those trained to a single stem, no other main growth being allowed, and all the side growths carefully removed. Large, fine fruit and abundant crops as a whole are secured by this method. Plants, however, in every case need not be confined solely to one stem; more may be allowed with good results, but each must be treated exactly like the single-stemmed examples, all lateral shoots being rigidly suppressed as they appear. The bunches of flowers are produced on the main stems quite sufficiently numerous to form good crops of fruit resembling in quantity "ropes of Onions."

#### SETTING THE BLOOMS.

There is not much difficulty in setting abundance of fruit when good culture is intelligently carried out. Everything is then favourable to proper fertilisation, provided the atmosphere is warm and dry in the middle of the day and a continuous current of fresh air freely circulates about the plants always. But as a sure and certain means of securing a good set it is very little trouble to go over each plant, gently tapping the bunches of bloom for the purpose of dispersing the pollen. Do this at, or shortly after midday. Some growers syringe lightly to effect the same purpose. I prefer the former way. Others never trouble at all about fertilisation, but leave it to correct methods of management affecting it naturally.

#### TOP-DRESSING.

As before stated the first top-dressing is given when fruiting commences. Only a slight dressing of a couple of inches is given each time, and it should consist of rich material. Loam and manure, with a little bonemeal, scot, and wood ashes all well combined together, form an admirable mixture which the plants appreciate, as evidenced by the avidity with which numerous white rootlets take possession of it and appear on the surface within a week after the material has been applied. I continue applying top-dressings of this kind until the pots are filled.

#### FEEDING.

Up to this stage feeding with liquid manure has not been practised because not found to be really necessary. The mass of roots now in possession of the plants through the multiplication of fibres from continual top-dressing renders something necessary which can penetrate quickly through the whole mass and carry rich nutriment with it. Nothing can do this like liquid manure made from animal deposits, varied sometimes with sprinklings of artificial manure well watered in. Clear soot water is an admirable stimulant, and can be easily made by mixing soot with water at the rate of a peck to thirty gallons, clarifying it—that is, making it clear—with a spadeful of quicklime well stirred in. After a few hours this will be clear enough for use.

#### THE IMPORTANCE OF AIR.

One of the most important requirements of Tomatoes is a constant supply of fresh air. I am convinced that many houses of Tomatoes are ruined through neglect of this. Tomatoes cannot succeed with weakened stems and soft foliage, the result of too little air. Such plants are prone to disease, especially if alternations of temperature should ensue. By this I mean a great disparity between the day and night temperature, so that an excessive deposition of moisture takes place upon the stems and foliage. This, going on for some time, produces disease, or rather prepares the plants for its reception. The antidote to disease is abundance of air from the early stages of growth, at the same time using a little fire heat, especially in dull cold weather, a buoyant dry temperature being very beneficial to the steady development of the plants, as well as the free setting and perfect flavouring of the fruit.

Perhaps the question may be asked, How is it that you recommend the employment of fire heat in summer, when it is a well-known fact that Tomatoes will succeed without? Well, the answer is that they succeed better with when it is used with discretion. I think it wise to continue it until the end of June, admitting plenty of air constantly to the house. After that period it may, in the best summer weather, be

dispensed with, resorting to it again, however, during wet sunless periods, as it is at these times that fungoid germs float in the atmosphere, and where they can find a suitable host plant on which to settle they forthwith develop and multiply amazingly fast. The aim of the cultivator should be to so grow and manage his plants that they become disease-proof. The air in the interior of the house mainly dry and kept in circulation by the constant entry of fresh will effect this most desirable end.

Cool house treatment in warm summers is prolific of good results. In houses of this kind the plants are best grown in pots, so that heavy

FIG. 68.—IRIS SAARI NAZARENSIS.

crops of green fruit in autumn may stand a chance of being ripened by the pots being conveyed to warm structures.

#### VARIETIES.

There are abundance of good varieties. The leading kinds at the present time are Ham Green Favourite, Conference, Challenger, Acquisition, Hackwood Park, and Perfection among the red fruit; while Blenheim Orange, Golden Queen, and Dessert are the best yellows. —E. D. S.

#### IRIS SAARI NAZARENSIS.

THE charming Iris for which Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, received an award of merit at the meeting of the Royal Horticultural Society on Tuesday, April 11th, will make a useful and welcome addition to the number of beautiful forms of this family already at our disposal. It is a dwarf grower, the stem rising about 9 inches above the ground level, and the flowers are very attractive. The standards are transparent white, the falls white dotted thickly with brown, and with a large purplish patch in the centre. Fig. 68 represents it.

**EVENTS OF THE WEEK.**—As announced elsewhere the principal events of horticultural interest to take place during the ensuing week will be the opening of the Gardening and Forestry Exhibition at Earl's Court on Saturday, May 13th. The inaugural ceremony will be performed by H.R.H. the Duke of York, K.G. The first summer Show of the Royal Botanic Society will be held in the Gardens at Regent's Park on Wednesday, May 17th, and an Orchid Show will open at the Earl's Court Exhibition on the 18th inst.

— **THE WEATHER IN LONDON.**—We have to again record a week of dry bright weather. No rain has fallen in the metropolis, although signs of it have appeared at various times. As we are going to press it is bright and sunny and with rather cold winds, which have been prevalent all the week. There has been about twelve hours of sunshine on most days.

— **WEATHER IN THE NORTH.**—The week ending 9th inst. has been dry, no rain falling since the 2nd. The drought has been strong on several days and some of the evenings especially cold from N.E. winds. The barometer is very high and steady. Hawthorn blossom is appearing here and there.—B. D., *S. Perthshire*.

— **NATIONAL TULIP SHOW.**—In consequence of the hot weather this Show will be held in the Botanical Gardens, Manchester, on Saturday next, the 13th inst, instead of on the 23rd of this month, as previously announced.

— **ACCIDENT TO MR. SAMUEL BARLOW.**—We regret to learn that this gentleman had a severe fall down some stairs in his Manchester warehouse last week, breaking his arm and being otherwise much bruised. This will, it is feared, compel his absence from the Tulip Show, but his flowers will be there. We are pleased to hear that Mr. Barlow is progressing favourably.

— **LATE GARDEN TULIPS.**—*Apropos* of Tulips at Long Ditton, some beds of Buonoventura, scarlet flaked with gold; Picotee, white with a wire edge of rosy carmine; and Golden Beauty, the deepest of all yellow Tulips, have been particularly admired, and perhaps not less so have Golden Eagle, Elegans, and Retroflexa. The flowers of all these mentioned are particularly suitable for vase decoration, and it is noteworthy that they remain fresh and beautiful for a considerable time in water.

— **WATERING AND MULCHING OLD FRUIT TREES.**—A correspondent referring to the practice of watering and mulching round the stems of large trees to a radius of 3 feet, thinks much more good would be done by similar applications twice the distance from the trunk, where there are more feeding roots. He has had to remove a Morello Cherry, and suckers have grown from the roots 30 feet from where the tree was planted, and thinks mulching round the stem merely would not have been of much benefit to that tree.

— **LARGE SNOWDROPS.**—It is scarcely possible from the description given by "W. T., *Blantyre*" (page 322), of the large Snowdrop at Craigbet, Renfrewshire, to say with any certainty what it may be. It is probably a seedling of exceptional merit, and the soil and climate appear to be favourable to the development of large flowers. The Galston Snowdrop does not appear to retain its exceptional size and stature in cultivation. It may be said, however, that the only garden in which it is growing is one apparently uncongenial to Snowdrops.—S. ARNOTT.

— **FIREPLACE DECORATIONS.**—For an ordinary sitting-room fireplace there is nothing more cool-looking during the summer and that gives less trouble than the common Hart's Tongue Fern (*Scelopendrium vulgare*). When the new leaves are fully developed toward the end of May dig up the roots, placing them in jam pots or deep saucers, in fact anything that will contain water. By standing the jars in the fireplace amongst moss or the ordinary paper shavings the drooping fronds look really handsome, and will last the whole summer if carefully watered when required, which is not often if the receptacles are of fair size.—E. M.

— **GARDENING APPOINTMENT.**—Mr. Geo. Clark, foreman to Mr. J. Lambert, Powis Castle, succeeds Mr. Sensical as head gardener to the Earl of Powis, Waleot Park, Shropshire.

— **PUBLIC GARDEN FOR BIRMINGHAM.**—It is reported that a sum of £4000 will be expended in laying out as a public garden and open space the churchyard of St. Paul's, Birmingham.

— **PROFESSOR OF BOTANY FOR BRESLAU.**—We understand that Dr. Pax, lately of Berlin, has been appointed Professor of Botany and Director of the Botanic Garden, Breslau, in succession to the late Professor Prantl.

— **EARLY STRAWBERRIES.**—We gathered our first dish of ripe Strawberries from the open air to-day, May 8th, the fruit large and of excellent flavour.—H. RICHARDS, *Roche Court, Salisbury*. [Our correspondent omits the name of the variety.]

— **EARLY GOOSEBERRIES.**—A correspondent informs us that Mr. Steel of Fulham gathered Gooseberries for market on April 26th. May 14th was the previous earliest date of gathering of which he has record. Mr. Steel is an extensive market gardener.

— **EARLY PEAS.**—As Mr. W. N. White has been comparing one season with another with respect to Strawberries, I thought a note with regard to Peas would be of interest. I have gathered my first dish of Peas this day, May 8th, William Hurst, sown on the 14th of February, 1893. Last year from a sowing on February 16th we gathered June 9th, or a month later than this year.—D. H. MOIEST, *Marley Hall Gardens, Eamouth*.

— **TIARELLA CORDIFOLIA.**—This False Mitrewort, or, as some call it, the Foam Flower, is well worthy of a place on the rockery or at the front of the herbaceous border, where flowers are appreciated during April and the early part of May. The bronzy marbled leaves are not the least attractive part of the plant; they also form a decided contrast to the pure white pedicel-shaped flower spike.

— **ALYSSUM SAXATILE COMPACTUM.**—Although regarded as a common plant this Madderwort provides a mass of colour on the rockery or elsewhere that no other plant does at this time of the year. The corymbose flower heads of yellow are produced in masses and last a long time in perfection. Although, as a spring bedding plant or as an edging to paths or borders, it is showy, yet on a large piece of rock where it can droop gracefully over seems its proper home. The same plants last a number of years.

— **GENTIANAS.**—The present hot and dry weather has been favourable to these plants, either on the rockery or in the borders, provided they were kept moist at the roots. The bright sun brought out the richness of colour to perfection. Although some persons prefer the smaller form of verna I like the massiveness of acaulis, the intensity of colour is more decided.—E. M.

— **WEATHER AT SWANMORE.**—Another week has passed since my last note on the weather, and still no rain here. With the exception of 0.04 inch recorded April 16th, and 0.02 inch April 29th, we have experienced sixty-four rainless days in succession. The prospect of a shower seems still as remote as ever. Altogether there has been a fall in the temperature; on several days the thermometer did not rise beyond 70° in the shade; once it has fallen as low as 35°. During the night of the 5th the lowest reading was 45°; the temperature during the day preceding being 87°. We are now, in addition to the great drought, experiencing strong easterly winds, which are parching, as well as being cold, and certainly not favourable to vegetation.—E. MOLYNEUX, *Swanmore Park*.

— **MARKET GARDENS AND THE DROUGHT.**—Some of the market gardeners in Middlesex and Surrey are suffering considerable loss in consequence of the dry weather. In the country districts of West Middlesex the drought is having a disastrous effect upon many of the gardens supplying the metropolitan markets. Especially is this the case in those localities where extensive grounds, fully planted with early vegetables, are at a distance from a water supply. Thousands of young plants are being dried up for want of moisture, and to market gardeners, as well as to farmers, the outlook is extremely gloomy. Never was an abundance of rain so sadly needed in country districts as at the present time. Although the rainfall in London has been excessively slight, from the country better accounts are to hand. The atmospheric conditions are now said to have undergone a complete change.

— **SEEDLING CLIVIAS.**—Messrs. John Laing & Sons send us seedling *Clivia* blooms to show the progress that is being made in these flowers. One of them is  $3\frac{1}{2}$  inches in diameter, colour orange red with white-and-yellow throat, the white very clearly defined.

— **GROS MAROC GRAPE IN COOL HOUSES.**—Will any of your correspondents having experience of Gros Maroc Grape say if it will do grafted on the Black Hamburg in a cool vinery? Will it ripen there?—B. J.

— **CRICKET.**—Many young gardeners, and some old ones, are interested in cricket, and may perhaps like to know that connected with the firm of Messrs. Sutton & Sons, Reading, there are three teams of players, and that no less than fifty matches are arranged for during the present season.

— **SPIDER-WEB SEDUM.**—It will be remembered by some that last year I made reference to the effects of this *Sedum* grown under glass. At the present time those grown under clear glass are prettily webbed, each rosette having from three to four tiers of young ones formed; while those grown under the rough glass scarcely show growth, and very little of the spider-web appearance. I have observed a similar effect upon other plants, and cuttings under the two kinds of glass.—W. T.

— **THE SCOUNDBEL SPARROW.**—As one who must plead guilty to harbouring the sparrow I fear any expressed sympathy with your able contributor "W. R. Raillem" (page 341) may be considered hypocritical. It is, however, tendered with the utmost sincerity, and I am disposed to attribute part of my immunity from damage by the pert little bird to the presence of the trough of the garden pump, which is always kept full of water, and is the resort of many thirsty birds. May I ask your correspondent if water is readily available in his orchard? His reply may help to clear up a matter in which there is some doubt.—S. ARNOTT.

— **M. ROTHSCHILD'S NEW WORK.**—We have received from M. Rothschild of Paris a French treatise upon the "sowing and planting" of forest trees, and generally upon the formation of hedges, shrubberies, and plantations in parks, gardens, and woodlands. It consists of some 350 pages of clearly printed and well-arranged matter from the hand of Mr. D. Cannon, who, though resident in France for the last fifteen years, is by birth an Englishman. The subject is treated in twelve chapters, and elucidated by the help of 380 engravings. Though adapted to serve as a practical handbook upon the subject, it also acts as a work of reference in indicating the authoritative sources from which a deeper knowledge of the treatment of trees may be obtained.

— **DEW.**—For some time past letters on how dew is produced have been going the round in our daily papers. I have always understood dew and rain to be in a sense synonymous, both being condensed evaporated moisture. That it depends entirely upon the electric state of the atmosphere how far the dew may be spread or separated, and whether it shall fall as dew or rain. Does not all dew first rise, or in other words, the dew that rises and the dew that falls are equal? it being simply a question of temperature whether it shall be held in suspension, or formed into fog, mist, or fall as dew. Independent of these remarks, dew appears to play a very important part in relation to electricity and the weather. When it dries up from the grass shortly after sunrise, and the mist gradually disappears, a fine day may be expected; but when the grass remains wet till far in the day rain follows.—T.

— **INSECTS ON FRUIT TREES.**—Just now fruit trees are being very generally attacked by caterpillars and other insects, and the Board of Agriculture has therefore very opportunely issued a leaflet detailing the best remedies to be adopted. The best and most common method is to syringe the trees with a softsoap mixture by means of one of the machines which are now well known. For this purpose several mixtures are given as follows:—1, The extract of 10 lbs. of quassia (obtained by boiling the quassia in water) mixed in 100 gallons of water, and with 7 lbs. of softsoap added. 2, The extract of 5 lbs. of quassia to 100 gallons of water, with 6 lbs. of softsoap and 4 pints of petroleum well stirred in. 3, The extract of 5 lbs. of quassia to 100 gallons of water, with 6 lbs. of softsoap and 4 pints of Calvert's (No. 5) carbolic acid. 4, 8 lbs. of softsoap, 2 lbs. of finely ground hellebore, and a quart of petroleum, boiled and well stirred together, and added to 100 gallons of water. In the case of all these mixtures (which can be made in proportionate quantities for small gardens) the softsoap is dissolved in a tub with hot water; the quassia chips are boiled in

water and put into another tub; where petroleum is used it should be well stirred up with boiling soap and water before it is added to the cold water. Besides the above harmless dressings a number of poisonous ones are described. These, however, require very great care in their use, and are, moreover, dangerous.

— **DRY SPRINGS.**—In 1852, after a long continuance of heavy rain, the weather cleared on the 14th of February, and there was no rain till the middle of May. The following year we had another mild winter and heavy rainfalls, but it cleared again on February 15th, and was fair for six weeks. During the year 1836 the weather was very cold, and crops were poor. The following winter the frost was severe remaining thirteen weeks, being the middle of April before thaw came; subsequently there were heavy falls of snow, and May was advanced before crops were sown. It was, however, a good summer that year, and not a late harvest. The years 1838-39-40-41 were similar in the spring to the present one; 1842 was cold throughout, 1843 was one of the finest and earliest seasons on record, then 1844-45 introduced the Potato disease; and although good seasons have intervened, the weather up till 1893 has been getting gradually colder.—W. T.

— **GOLD-LACED POLYANTHUSES.**—I do not know who made the award, but I was astonished to find that I should so easily be able to discern what professed experts had failed to see—that in the three gold-laced Polyanthuses placed first at the Auricula Show at the Drill Hall, Napoleon III., a rather coarse red ground, was shown twice, but the second plant under the name of John Bright, a most easily recognised black ground. I drew the attention of a prominent member of the Society to the impropriety, and he saw as well as I did what was so wrong. The mistake could not have been unintentional, and it was astonishing, with one or two plants of John Bright close by, the judges should have made such a mistake. Lancier, red ground, and Lancashire Hero, if it were true, black ground, were the best. All the others were much below par indeed. Unless grown to bring out the finer points in gold-laced Polyanthuses it seems hardly worth growing them at all.—A. D.

— **SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, FOR APRIL.**—Mean temperature of month,  $48^{\circ}7'$ ; maximum on 20th and 24th,  $74^{\circ}8'$ ; minimum on the 12th,  $24^{\circ}2'$ ; maximum in sun on the 20th,  $126^{\circ}4'$ ; minimum on the grass on the 12th,  $16^{\circ}1'$ ; mean temperature of air at 9 A.M.,  $48^{\circ}3'$ ; mean temperature of soil 1 foot deep,  $47^{\circ}9'$ . Nights below  $32^{\circ}$ , in shade nine, on grass nineteen. Total duration of sunshine 218 hours, or 52 per cent. of possible duration; we had two sunless days. Total rainfall, 0.34 inch; rain fell on four days. Average velocity of wind, 6.7 miles per hour; velocity exceeded 400 miles on one day, and fell short of 100 miles on eight days. Approximate averages for April:—Mean temperature,  $45^{\circ}4'$ ; sunshine, 123 hours; rainfall, 1.65 inch. The warmest and driest April for at least seventeen years; the daily range of temperature was exceptionally large, and whereas the day temperatures were  $8^{\circ}$  above the mean, the night temperatures were  $2^{\circ}$  below the mean. The percentage of sunshine is larger than in any month since the record commenced in 1881. The total rainfall for March and April amounts to less than an inch. Vegetation is about a month earlier than last year, but rain is much needed. Hawthorn and Horse Chestnut in bloom on the 23rd. Queen wasps very numerous this spring.—J. MALLENDER.

— **THE WEATHER LAST MONTH.**—The weather during April was very dry. The first fifteen days gave no rain, and thus completed a period of twenty-nine days without a drop of rain. We had twenty-four bright days, twelve of which were clear. The wind was in an easterly direction twenty-two days. Barometer—highest reading, 30.57 at 9 A.M. on 8th; lowest, 29.88 at 9 P.M. on 29th. Total rainfall was 0.43 inch, which fell on four days, the greatest daily fall being 0.25 inch on the 16th; this is 1.49 inch below the average for the month, making the total fall for the year up to the end of April 4.22 inches, which is 2.80 inches below the average for this period. Highest shade temperature,  $80^{\circ}$  on the 20th; lowest,  $21^{\circ}$  on the 14th; lowest on the grass,  $15^{\circ}$  on 14th. Mean maximum temperature,  $63^{\circ}90'$ ; mean minimum,  $36^{\circ}23'$ . Mean temperature of the month,  $50^{\circ}06'$ . Most of the trees were in leaf by the end of the third week. The Oak commenced to expand on 27th. Hawthorn flowers began to open on 24th. The nightingale was first heard here on 20th, and the cuckoo on 22nd. The garden spring ran 20 gallons per minute on the 30th. The continued drought is causing great inconvenience to farmers and others in this neighbourhood. Late sown corn is very patchy, and the hay crop will be a poor one.—W. H. DIVERS, *Ketton Hall Gardens, Stamford.*

— **ROCKERY PHLOXES.**—At the present time Phloxes of the subulata section (commonly called Ground or Moss Pinks) are exceedingly showy on the rockery. This section of hardy, dwarf-growing plants is not nearly cultivated as much as its merits deserve. Although the rockery is perhaps the more situation for their growth it is not absolutely necessary that they grow there only. As edgings to paths or borders where a few stones might be arranged to form a narrow border, success would be assured providing of course the drainage was sufficient in the case of heavy and retentive soil. In soil of a light character and when thin in bulk, I find these Phloxes require abundance of moisture at the roots to keep them in a flourishing condition in the sunniest places on the rockery. It is here where they thrive the best, enjoying the full sunlight with a moist base. In patches of not less than 2 feet square of each colour a grand display is effected. To me it is surprising that they are not more extensively grown, considering the ease with which a stock of plants may be worked up. Good varieties are Nelsoni, pure white; The Bride, white, with red centre; Vivid, fiery rose colour; Pallida, rose, shaded lilac; Frondosa, bright rose colour; and atropurpurea, purplish rose, with a crimson eye.—E. M.

— **THE WAKEFIELD PAXTON SOCIETY.**—At the recent meeting of the members of this Society Mr. H. Crowther, curator of the Leeds Museum, delivered an extremely interesting and instructive discourse on "Soils and Manures." Mr. Crowther first mentioned how soils are formed by the disintegration of rocks, and described the different kinds of soils produced by the mixture of loam, sand, clay, calcarene, and marl, with humus resulting from vegetal action. In adverting to the four-course system of agriculture he showed how each crop found in the soil its most appropriate aliment, and said our forefathers must have been very keen observers, for they had by experience hit on true principles, so that even we with our scientific knowledge could not do much better than they, though we worked with reason, whereas they laboured in the dark. He then dealt with the various manurial agents, showing the chemical constituents of each, and demonstrating why certain soils and certain crops need certain manures, and explaining their suitability and unsuitability in other cases. Many diagrams and illustrations were shown, portraying the marvellous results of the application of right principles in manuring, as gained by experimental culture by Lawes, Gilbert, and others.

— **THE TEA INDUSTRY IN CEYLON.**—In his report for 1892 Dr. Trimen, the Director of the Royal Botanic Gardens, Ceylon, refers to the fact that of every 100 lbs. of tea consumed in England during the year 84 lbs. were of British growth, viz., 53 in India and 31 in Ceylon, only 16 lbs. being the produce of China. There was an increase of nearly 2,000,000 lbs. in the direct export of Ceylon tea to Australia, viz., 5,166,154 lbs. against 3,210,598 lbs. in 1891; and Dr. Trimen thinks that the costly advertisement at the forthcoming Exhibition in Chicago may reasonably be expected to lead to a large sale in the future in America. Ceylon, he says, urgently needs this; for while there is no reason to fear any drawback to continued success as far as cultivation and manufacture are concerned, there is a real danger of over-production; and its consideration as a possibility, by no means remote, induces him earnestly to recommend those concerned to devote some portions of their land to other cultivations. In the low-country especially much caution should be exercised in opening further land in tea estates. One result of the enormous development of the tea industry in the island is unfortunate. The industry so overshadows all other cultivations that there is now little room for trial or experiment with smaller products on estates, and not much stimulus to investigate them in the Botanic Gardens.

— **HONEY-PRODUCING PLANTS IN AUSTRALIA.**—The Agricultural Department of New South Wales has been making a series of interesting and useful inquiries as to the plants most visited by bees in the various districts of the colony. Some of the results are set forth in a recent number of the Department's "Gazette." It has been clearly proved that the flora of Australia includes honey-producing trees, shrubs, and plants of a high standard of excellence; the honey produced by bees in the near neighbourhood of the forest being of the finest quality, and having few (if any) faults. While a Gum Tree is in bloom the bee will pass over the most tempting plant in a garden, and wing its way to the borders of the bush; but, on the other hand, a field of Maize in tassel is a source of the greatest pleasure to the busy little workers, who swarm in countless numbers, collecting the pollen so necessary for their wants. The plants which next seem to have the greatest attraction are the fruit trees, familiarly called

summer fruits. Clover (both white and red) yields a large quantity of first-rate honey, and bees kept at places where Clover grows never fail to visit the modest flowers of the plant; Dandelion, also, is a valuable honey-yielding flower, and is noted in all districts from Albury to Tenterfield. As to the size and colour of the flowers most affected by the bees, much diversity of opinion exists among apiarists, and in the face of the very conflicting replies, the "Gazette" thinks it would be vain to try to determine what coloured flowers are most attractive.—(Nature.)

DENDROBIUM BRYMERIANUM.

THIS is a beautiful Orchid, and is remarkable on account of the delicate, branching filaments of the lip, forming a deep fringe or beard, which is its chief attraction. The flower is a golden yellow throughout. The plant should be potted in good peat used in a very rough state, with a little moss and charcoal, and grown in a warm moist house in summer. In winter it requires rather more drying than the majority of the evergreen kinds.

CYMBIDIUM LOWIANUM.

This species is a most useful, distinct, and handsome Orchid, easily grown, free flowering, and very long lasting. The spikes on well grown plants attain a height of 2 or 3 feet, and are clothed with flowers almost from top to bottom, and as these will remain fresh for nine or ten weeks it is very useful for exhibition. It has long arching flag-shaped foliage and light green bulbs.

It succeeds best under pot culture, and may be potted in peat, light turfy loam, and moss in about equal proportions. Many growers recommend a portion of sand, but this is sure sooner or later to run together, spoiling the compost by preventing aëration, and destroying that "sweet" condition of the soil which is so desirable.

This Orchid requires plenty of heat and moisture and a rather shady position. From the time the flower spikes show until they are showing colour occasional applications of manure water are necessary, that made from cow manure being probably the most suitable. The flowering season is usually from February to May or June.—H. RICHARDS.

HYBRID ZYGOPETALUMS.

IN our last issue a brief allusion was made to Part ix. of Messrs. J. Veitch & Sons' "Manual of Orchidaceous Plants," and we then remarked that an occasion may arise for a further reference to this excellent work. This opportunity has now come, and we have pleasure in reproducing some notes on hybrid Zygopetalums with an illustration of *Z. Sedeni* (fig. 69), for which we are indebted to Messrs. Veitch & Sons. The kind figured is of exceptional interest, inasmuch as it was the first hybrid Zygopetalum raised, this being done by Mr. Seden some years ago. A few additions have since then been made, but as will be seen by the following quotations the number of hybrid Zygopetalums has not swelled to any considerable extent.

"Hybrids between species of Zygopetalums are still few in number, and of those that have been raised, the vigorous growing type species Zygopetalum Mackayi, its variety crinitum and *Z. maxillare* have participated in the parentage of all of them. Of the four hybrids described below, the first two are results of crosses effected between the two species mentioned by different operators, one using the original *Z. Mackayi*, and the other its variety crinitum; as a natural consequence the two hybrids very closely resemble each other. A fairly numerous progeny was obtained from both crosses.

"The last two are of exceptional interest, for they are generic crosses between Zygopetalum and Colax. In conformity with the nomenclature adopted in this work for bigeneric hybrids, they take the name of Zygocolax. In both cases the progeny was extremely restricted."

**ZYGOPETALUM CLAYI.**—This is the result of a cross between *Z. Mackayi crinitum* and *Z. maxillare*, and is described as follows:—"Pseudo-bulbs and leaves intermediate. Flowers as large as those of the seed parent; sepals and petals brownish purple, with a narrow green margin, and sometimes with a few narrow transverse

green streaks; lip nearly as in pollen parent, purplish blue with darker lines; the ridges of the crest dark violet blue, the furrows whitish; column violet purple above, streaked below the stigma." It was raised by Colonel Clay of Wallassy, Birkenhead.

**ZYGOPETALUM SEDENI.**—We are told that this is the result of a cross between *Z. maxillare* and *Z. Mackayi*. "Pseudo-bulbs and leaves nearly as in *Z. maxillare*; racemes 6 to 9 flowered; flowers intermediate in size between those of the parents; sepals and petals brownish purple with a metallic gloss, and sometimes with two or

rotund, erect, indigo blue, the fleshy crest between them nearly as in *Zygopetalum maxillare*, the ridges blue and the furrows white; the front lobe transversely roundish, oblong, indigo blue, sparingly mottled with white. Column broad, purplish blue, anthers white." This was raised by Mr. Seden at Messrs. Veitch & Son's nursery, and is described as "the handsomest of the *Zygopetalum* hybrids yet obtained."

**ZYGOCOLAX VEITCHI.**—This is a bigeneric hybrid between *Zygopetalum Mackayi* and *Colax jugosus*. "Pseudo-bulbs broader

FIG. 69.—*ZYGOPETALUM SEDENI*.

three pale transverse bands; lip bright violet blue, more or less striated; crest and column dark violet blue." Raised by Mr. Seden at Messrs. Veitch & Son's nursery, and figured in the illustration.

**ZYGOCOLAX LEOPARDINUS.**—An interesting bigeneric hybrid between *Zygopetalum* and *Colax jugosus*. "Pseudo-bulbs ovoid, compressed, 1 to 2 inches long, diphyllous; leaves linear-lanceolate, acute, 6 to 9 inches long; racemes 3 to 5 flowered; flowers 2 inches in diameter; sepals and petals oblong-lanceolate, whitish spotted and marked with brown purple; lip three-lobed, the side lobes

and shorter than in *Colax jugosus*; the leaves narrower, and the racemes shorter and fewer flowered than in *Zygopetalum Mackayi*. Flowers 3 inches across the lateral petals; sepals and petals similar and sub-equal, spreading, broader than in the *Zygopetalum*, narrower than in the *Colax*, light yellow green, much spotted and blotched with brown-purple; lip with two basal auricles, sub-orbicular, the central area white with radiating lines of violet-purple papillae, the marginal area violet-purple striated; column yellow-green spotted with brown-purple." This was also raised by Mr. Seden.

## AN AMERICAN ROSE BOOK.

MR. H. B. ELLWANGER favours us with a copy of his treatise on the Rose.\* It is a substantial volume of 310 pages, clearly printed on stout paper, very handy, and admirably produced; a re-issue, and though not up to date in varieties is readable, and contains information that is the opposite of a fleeting character. The author says, "This book neither expects nor desires to supersede its predecessors, but asks admission to their fellowship, hoping that it contains enough that is distinctive and of merit to be considered companionable." Most readers of the book will, we think, consider those hopes justified. The introduction to the book is new, and written by the father of the author, Mr. George H. Ellwanger, and from this we make a few citations:—

As producers of new Roses, the French continue in the lead, though an extremely large proportion of recent French varieties are mediocre or useless for general cultivation, or resemble so closely other well-known sorts as to be of no increased value in themselves. The incentive to produce new kinds, it should be remembered, is especially great in France, where 25 francs apiece is demanded for a novelty which may be good, bad, or indifferent, but whose description is invariably *couleur de Rose*. Not that in the majority of cases they are sent out with the deliberate design to deceive—the Rose owes too much to Gallic intelligence, enthusiasm, and pains for a charge of this nature to be made. But to the raiser, a new variety, fostered by his care and travail, naturally possesses enhanced attractions which may not be equally perceptible to the public; while new things are always apt to be more attractive at first sight than upon closer familiarity.

The English, who come next as producers of new Roses, continue to send out some excellent novelties, and, with our own growers, exercise better care and more reliability in selecting than the French. America has contributed largely those kinds suitable for forcing under glass; and of American Roses produced of recent years it may be said they are nearly all valuable as proved by general cultivation.

Among new Roses there has been nothing better produced in their respective classes than Baroness Rothschild and Mme. Gabriel Luizet in pink, La France in silvery rose, Mabel Morrison in white, M<sup>re</sup>chal Niel in yellow, Catherine Mermet in delicate blush, Gloire de Dijon in rose-salmon, Marie Rady in fragrant and vivid vermilion, and G<sup>en</sup>eral Jacqueminot in its brilliant scented crimson bud. Other new varieties have been added, to be sure, possessing especial merits. Of distinct sorts recently introduced may be particularly instanced:—*Teas*: Mme. Hoste (Guillot, 1887), Mme. de Watteville (Guillot fils, 1884), Mme. Pierre Guillot (Guillot, 1888), Papa Gontier (Nabonnand, 1883), Queen (Dingee and Conard Co., 1890), Climbing Niphotos (Keynes & Co., 1889), Climbing Perle des Jardins (J. Henderson, 1890). *Hybrid Remontants*: American Beauty (Hon. G. Bancroft, 1885), Earl of Dufferin (A. Dickson & Sons, 1887); Gloire de Margottin (Margottin, 1887), Lady Helen Stuart (A. Dickson & Sons, 1887); Mrs. John Laing (Bennett, 1887). *Hybrid Rugosa*: Mme. G. Bruant (Bruant, 1888). *Bourbon*: Mrs. Degraw (Burgess, 1887). *Hybrid Tea*: Meteor (Bennett, 1887). *Polyantha*: Clothilde Soupert (Soupert & Notting, 1890).

Of the numerous varieties produced since the present volume was written, few possess greater claims to recognition than the Rose raised by the author, and named by him after the distinguished pomologist, Marshall P. Wilder—one of the most fragrant, beautiful, and free flowering of the Hybrid Remontant class, and equalled by few Roses as an autumnal bloomer. By many American Beauty, supposed to be a cross from Mme. Victor Verdier and a Tea of unknown origin, is regarded as the finest of Roses. In its class it is certainly unrivalled, with its immense fragrant blossoms, beautiful violet-red colour, long stems, and luxuriant foliage. But it is essentially a Rose for growing under glass, and cannot take the place of numerous old-time favourites as an out-of-door flower.

So many varieties now exist, however, that growers should exercise redoubled care in sending out anything as a novelty which does not possess intrinsic merits of its own. It may still be reiterated that among the thousands of varieties included in the genus *Rosa* there exist far too many similar colours, and, equally, too many varieties whose colour fades with the first warm sun, though many of the latter class prove more satisfactory when grown in a moist cool climate. There might be an abundant weeding of varieties possessing a purplish-magenta shade, to the decided advantage of both growers and gardens. Too little attention also is paid in the raising of new varieties and in deciding the merits of exhibition Roses, both here and abroad, to one of the most precious virtues of the Rose—fragrance—

The coming Rose,  
The very fairest flower, they say, that blows,  
Such scent she hath.

Of Roses for forcing in this country, the following may be mentioned as representative kinds, although in respect to choice of varieties, florists differ somewhat in different localities; while even in the same locality some succeed admirably with certain kinds, where others fail. A large proportion of the following are grown by nearly all leading florists throughout the country:—*Teas*: Bride, Bon Silène, Catherine Mermet, Mme. Cusin, Mme. Hoste, Mme. de Watteville, Niphotos, Papa Gontier, Perle des Jardins,

\* New York: Dodd, Mead, & Co.

Sunset. *Hybrid Teas*: Duchess of Albany, La France, Meteor, Souvenir de Wooton. *Hybrid China*: Magna Charta. *Hybrid Remontant*: American Beauty, Anne de Diesbach, Barcess Rothschild, G<sup>en</sup>eral Jacqueminot, Mabel Morrison, Mme. Gabriel Luizet, Mrs. John Laing, Paul Neyron, Ulrich Brunner.

When well grown under glass, few Roses equal Souvenir de la Malmaison for its delicate refined beauty, and the delicious attar-of-rose fragrance exhaled by its flesh-coloured petals—a fragrance observable in a less degree in Caroline de Sansal and some other varieties. M<sup>re</sup>chal Niel, in like manner, has no equal in its splendid yellow full-blown flower, and its highly Tea-scented perfume; but it is unfortunately limited to a single lode of gold during the season. With regard to odours, great variety exists among the different kinds—some recalling a luscious fruit in their particular fragrance, others exhaling a spicy aroma, and others still comparable to nothing else but the pure uncloying odour of the Rose itself.

As for out-of-door Roses, who may state the favourites among so many of the fair? Let each one decide their merits for himself; and, revelling in their wealth of beauty as it unfolds with each recurring blossom-tide, repeat with Omar:—

Look to the blowing Rose about us—"Lo,  
Laughing," she says, "into the world I blow,  
At once the silken tassel of my purse  
Tear, and its treasure on the garden throw."

## PROSPECTS OF AND NOTES ON HARDY FRUITS.

IN this locality the hardy fruit crop may be considered fairly safe from the effects of frost, and on the whole is very promising. The recent hot weather, accompanied with dry air, has rendered the bulk of the blossom free from what little frost has been experienced during the last fortnight. Even the latest varieties of Apples may now fairly be looked upon as being safe, as in most instances the petals of late flowering varieties are commencing to fall.

Gooseberries have suffered more than any other kind of fruit. The drought and piercing east winds have not only given the trees in many cases a full crop of red spider, but the young growth has been seriously interfered with; small puny leaves of a pale colour have taken the place of the deep green leathery foliage and vigorous shoots. The trees in many gardens are now in a miserable plight in consequence of this pest. The same results are apparent in market gardens in the neighbourhood. Caterpillars (called by the natives "palivers") are plentiful already. A dose of hellebore powder in the evening, and a vigorous washing with clean water applied with force through the garden engine, will cleanse the trees of this pest. For the defect in growth I have thoroughly soaked the roots of the trees with liquid manure as a filip to growth, and drenched the leaves well with clear water for the red spider.

Red and White Currants are most promising in every way, the hot and dry weather being favourable to the fertilisation of the bloom. Black Currants are fairly promising if the trees keep clear of aphides, which are apt to be troublesome during hot and dry weather.

Strawberries on the whole are promising, although many of the early blooms were spoilt by the sharp frost on the morning of April 11th, and the two successive mornings. In this garden the drought of the last two years, coupled with some severe frost during the winter, have thinned the rows of plants rather, but in the districts more favoured and better suited for Strawberry culture the plants promise remarkably well. All that is required is a thorough soaking rain to cause the fruit to swell quickly and well.

Peaches and Nectarines on south, east, and west walls have set remarkably heavy crops of fruit, the first swelling being apparently quite satisfactory considering the heavy burden of aphides the foliage has to carry. I never saw the trees so infested as they are this year, in spite of repeated applications of insecticides of various kinds. The cold winds experienced a short time since prevented the usual remedies being promptly administered, hence the enemy has progressed rather too rapidly. However, persistent waging of war will rid the trees directly of these pests. As a whole, the trees are not much affected by "blister" this year. Copious supplies of water to the roots close to the wall, and a mulching with half-decayed stable manure, coupled with an early thinning of surplus fruit will do much towards encouraging satisfactory results.

Pears promise a full crop of fruit, both on walls and in the open. At present the trees appear like escaping that wholesale dropping of the fruit in its initiatory stage. The foliage is remarkably free from grubs or insects of any kind.

Plums flowered most abundantly, both on walls and in the open, but they do not promise a heavy crop as yet, many of the tiny fruit appear to lag behind. This I attribute to cold winds at the time when the bloom was fully developed and to drought since. Damsons look rather less promising still; the trees are so heavily attacked with green fly that the fruit cannot swell freely. The bitter east wind which many trees were exposed to while in bloom no doubt interfered with proper fertilisation.

Apples are perhaps the most promising of all; I never saw the trees so profusely flowered as they were in all directions, and what is most remarkable the last year's growth is in innumerable cases wreathed with blossom to the very tips. I do not remember seeing this before. Such varieties as Lane's Prince Albert, Ecklinville, Cox's Orange Pippin, and even Warner's King show this remarkable floriferousness. I do not consider it is an advantage to the trees, rather the reverse, as the current

year's growth must be interfered with to some extent. It shows how well the wood was matured last year while it was being made, thus laying the foundation for the future crop of fruit. I always relieve newly planted bush trees of three-fourths of the bloom buds directly they form, reducing these later on, and in the case of standards I pluck off all. Much better growth is then obtained the first year, and this is of far more importance in the future than a full crop of fruit the first year. An abundance of moisture at the roots, afterwards mulching the surface with manure, will do much towards securing a full crop of good fruit and avoiding that wholesale self-thinning which happens to too great an extent in some seasons.

Cherries are no exception to the rule for a full crop of fruit. On trees on walls the first swelling appears to be quite satisfactory; the foliage, too, is particularly exempt from the usual full crop of black fly so far. Various other kinds of fruit, including Medlars, outdoor Figs, Quinces, and several forms of Crabs, such as the Siberians, and *Pyrus Malus rosea*, both of which are highly prized for their fruit, all promise heavy crops.

All kinds of fruit will give the best return that receive the necessary amount of attention in supplying the roots with moisture when required, and the foliage free from insect pests, which, not only blight the immediate fruit crops, but injure the next season's prospect by interfering with the growth and maturation of the wood.

As showing the difference between two seasons here a standard tree of Apple Worcester Pearmain was fully in bloom last year, May 10th. This tree was in flower April 20th this year.—E. MOLYNEUX, *Swanmore Park, Hants.*

It is early to speak of fruit prospects, but they are sufficiently clear to say that the fruit promise will be falsified. The actual state at the moment is this—Pears, except on walls, a failure; Plums and Damsons promise fairly; Apples are suffering very severely from attacks of weevil, caterpillar, and, worst of all, I think, *Psylla mali*, rendering it impossible to speak definitely at present; Peaches, Nectarines, and Apricots have set a heavy crop.

The Gooseberry caterpillar has stripped many bushes in this part. Currants and Raspberries promise a fair crop. In face of the insect attack and the prolonged drought no opinion is worth much. We find "Stott's Killmright" kills most of our enemies if carefully applied at proper strengths, but as the various eggs continue to hatch out, it is necessary to repeat the sprayings. The season is one month earlier than last year.—S. T. WRIGHT, *Glewston Court Gardens, Ross.*

EVERYWHERE on the Vale of Clyde the fruit prospects are most promising, and with the absence of frost in May point to glutted markets, and possibly low prices, especially with those who have made no provision with an alternative to preserve the fruit. It is not yet too late for that. Evaporators, boilers, and other accessories can be had at a reasonable price, and those who "go in" for these in time will not regret it.—W. T.

TAKING the Pear crop as a whole, I have here a most excellent show of fruit. The older trees are the shyest—I mean the trees from eighty to a hundred years old—in the orchard. Windsor and Catillac are sparsely set, whilst a younger tree by fifty years of Beurré Hardy which is usually shy, in the same orchard, is well flowered and set. Maréchal de Cour, which is also shy as a bearer in the orchard, is fairly well set this year. Jargonelles are well set, and especially so Beurré d'Amanlis. Louise Bonne de Jersey and Pitmaston Duchess (here fruiting most prolifically as a tree in the open), Doyenné du Comice, and Beurré Superfin, usually shy, are fairly well set this season. Williams' Bon Chrétien and its ally Souvenir du Congrès are generally good, and are so this year. My favourite midseason Pear, Fondante du Charneuses, has a fine crop well set.

Fondante d'Automne and Winter Nelis, not ordinarily constant fruiters, are full and setting well. Joséphine de Malines is the bardest of flower of all my Pears this year, as Baronne de Mello is the fullest, being one sheet of bloom a week past, and now setting well; Beurré d'Anjou was white over with flowers, but the set of fruit is only indifferent; Triomphe de Jodoigne looks like giving some good fruit; Doyenné Boussouch and Beurré Hardy, crown grafted three years ago on a nameless and worthless stock, are well set all over; Beurré Diel is an average set; Clapp's Favourite is well set, and also its near growing neighbour Rivers' Fertility, well named as to quantity, but not proved, so far, up to dessert fruit quality. These Pear remarks apply to trees and bushes in the open.

My wall Pears are not quite up to average produce this year. Marie Louise has a few, Easter Beurré a few, Beurré Diel scarcely any, Brown Beurré the same, Maréchal de Cour well set, but Nec Plus Meuris, which usually I can rely upon for a crop, is almost bare this season.—P. H. N.

#### POCKET-BOOK NOTES.

I AM full of sympathy with "W. P. W." in his opening to his valuable "Notes by the Way" in last week's *Journal of Horticulture*. No doubt many gardeners' notebooks are crammed full of really useful practical notes which would be of immense service to their brethren were they only printed. I am, however, rather of opinion that those notes do not get into print just in the same way that many proposed and thought-out kindly letters to friends do not get into fact by

reason of the supposed necessity of, and unreadiness of, the orthodox means of letter writing, pens and ink. As we get on in life the practical duties of the daily round so exhaust us that in the evening, and even through the rest periods of the day, we find the armchair and the daily or gardening paper, or monthly, a book with perhaps the pipe of peace more to our comfort than the going to the desk, getting out paper, pens, and ink, and deliberately beginning to write either letter or gardening note. We, therefore, put off the writing, and the habit of putting off grows like other habits, until at last the getting out of these writing materials becomes—except to professional writers, of course—a nuisance.

Now the editorial instructions to correspondents being emphatic that communications shall be written in ink and on one side of the paper, &c., bars many a good note from getting into their hands, as also the generally accepted idea that letters must be written in ink, though not on one side of the paper, hinders many a kindly letter from being written and sent. I think it would be a good thing if we could break down this rule, and as far as I am myself concerned with respect to letter writing generally to intimate friends and own relatives, I scarcely ever use pen and ink. I find the 6d. reporting books (Fono series, No. 5) admirable for my purpose. The leaves are so fixed in them that they draw out at the end without tearing. (These notes are written on such pages.) With this book and a Winsor and Newton or Rowney's B B pencil I can sit down in the garden at an odd five minutes and jot off a letter to a friend without any trouble, and I can testify that many letters to friends do get so written that would not be written if they waited for pen and ink. I specially mention a B B pencil. It makes a good black mark, not too soft or loose to rub out without that everlasting putting to the lips to moisten, which is inevitable with the commonly used H B. Indeed, no gardener ought to use a H B unless for drawing purposes. A "B B" is also best for writing on wooden labels with. My contention, therefore, from all this is, that if editors would relax their rules it would be good for many a busy practical man with a plethoric notebook and good resolutions like "W. P. W." and we, the readers of the *Journal of Horticulture* and other gardening papers would benefit in consequence. Can it be done?—P. H. N.

[If all our correspondents could use the pencil as "P. H. N." has done we should not trouble about ink; but some pencillings are so obscure when they reach us that they could only be hurtful to the eyes of compositors, who in dull and foggy weather have to work the whole day under gas jets; but there is an important practical reason for requiring matter for press to be written only on side of the paper, and we cannot relax that rule. Send us some more well pencilled leaves from your pocket book, Mr. "P. H. N." You can do them when sitting on a flower pot under a tree in hot weather, in the potting shed when it rains, and others may do likewise who use B.B. pencils on white paper, the same as we are now using. Many a bright idea and good suggestion is lost to the world by want of recording them first in a pocket book, then in the press].

#### GRAFTING: DOES THE WOOD OF THE STOCK AND SCION UNITE?

REFERRING to this matter on page 343, I may say that a similar question was asked me when giving an illustrated lecture on grafting fruit trees at Inkberrow, under the Worcestershire Technical Education Committee of the County Council, some weeks ago. At first I was quite under the impression that the woods united, and made a firm and lasting solid growth; but on the matter being discussed by the questioner, on second thoughts, which are sometimes best, I felt quite inclined to alter my opinion, especially on some of the principles of inserting grafts, of which I showed about half a dozen of the best. I consider that splice grafting on a small stock, with same size of graft, would be the best test.—J. HAM.

To disprove that the stock and scion unite I have had many an argument, and even when I produced evidence of cut timber, both where grafted or where the bark and wood had covered a lopped-off branch, the disputants would declare there was something wrong, as the wood of the stock and that of the scion did unite. I have cut hundreds of such specimens, and never yet failed to see the dark coloured portions of the ununited wood, so can corroborate all you say on the subject.—W. T.

I FIND it very difficult to believe that no real junction of the hard or heart wood of trees takes place after the process of grafting. Budded trees are of course very different, but there must be myriads of old trees about the country which have grafted heads, and it seems incredible, assuming no real junction of the heart wood has taken place, that they should withstand rough winds and not snap off at the junction. Is it not the case that trees thus worked, if they do not really unite, the wood yet secretes a sappy compound which fills the interstice formed by the grafting, and acts very much as glue does to dead wood by holding the sections tight together?

The section of tree figured at page 343 is a somewhat unusual one for a grafted tree to show, because as a rule the graft exceeds the stock in dimensions, whilst in the illustration the case is so much reversed that the stock is double the size of the graft. That would rather tend to show that the grafting was at the first badly done, or else that the stock and graft were badly assorted. Still, grafting as ordinarily done when stocks are young, and of course if such non-union exists it would

apply solely to such portion of the stock and graft as was originally worked, whilst all new wood made later would, of course, enclose or cover up the interstice.

The chief interest in relation to this matter is found in the re-grafting of old fruit trees or similar stocks so much advised, and here as the wood surfaces are brought together longitudinally rather than transversely I am disposed to think that a real union does result. The matter is well worthy of further elucidation.—A. D.

## ROYAL HORTICULTURAL SOCIETY.

MAY 9TH.

THE Drill Hall on this occasion presented a gay appearance, the building being well filled with miscellaneous plants and flowers. Orchids were fairly well shown, and stove, greenhouse, and hardy plants were well represented. A few fruits and vegetables were staged.

FRUIT COMMITTEE.—Present: Phillip Crowley, Esq. (in the chair); and Rev. W. Wilks, Dr. Hogg, with Messrs. T. F. Rivers, John Lee, Harrison Weir, G. Bunyard, G. Taber, T. J. Saltmarsh, G. T. Miles, A. Dean, A. J. Laing, W. Bates, G. Sage, G. Wythes, J. Hudson, G. Reynolds, F. Q. Lane, J. Smith, H. Balderson, and J. Wright.

Mr. E. Gilman, The Gardens, Ingestre, Stafford, sent seedling Melons from Ingestre Hybrid  $\times$  Hero of Lockinge  $\times$  Countess. One of them, a medium-sized fruit, yellow rind, netted, greenish-white flesh, sweet and juicy, was granted an award of merit. Mr. Riches, gardener to Dr. Frankland, Redhill, sent a new green-fleshed Melon, handsome, but decidedly unripe, and the Committee desired to see the variety again as one of promise.

Mr. W. Igzulden, Marston Gardens, Frome, sent ripe fruits of Noble Strawberry gathered from the open ground, the plants having been protected with mats when in flower. The fruits were very good, but paler and more pointed than usual. They were ripe exactly a month earlier than the first fruits of last year of the same variety on the same border (vote of thanks).

A cultural commendation was unanimously awarded to Mr. G. Wythes for splendid fruits of Brown Turkey Fig; also a vote of thanks for fine clusters of the Old Red Tomato.

Mr. Leach, Albury Park Gardens, sent a dish of Chelsea Gem Peas, planted January, 1893, from seed sown in December. Mr. Leach also sent plants bearing a heavy crop of Runner Beans, grown in a Peach house. The variety is one of Messrs. Sutton's, and named "Delicious." The pods resemble those of Dwarf Kidney Beans (but larger) rather than Scarlet Runners, and are said to be of the highest quality. The crop was certainly bountiful. Very good Lettuces—Tennis Ball, Leach's Winter Cos and Brown Cos were sent from the same garden, the Winter Cos turning in like a summer Lettuce. A vote of thanks was accorded to Mr. Leach for his exhibits. Mr. T. W. Bond, gardener to C. L. N. Ingram, Esq., Elstead House, Godalming, sent neat conical heads of Veitch's Earliest of All Cabbage, from seed sown on a gentle hotbed January 22nd (vote of thanks).

Mr. E. Beckett sent from Aldenham Park Gardens splendid examples of Snowdrop Potato, handsome fruits of Reading Perfection Tomato, and an excellent dish of British Queen Strawberries, the finest specimens of the respective kinds placed before the Committee this year, and a cultural commendation was promptly accorded.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair), Messrs. J. Fraser, Owen Thomas, H. Herbst, C. F. Bause, G. Stevens, H. B. May, C. T. Druery, J. Jennings, W. C. Leach, G. Nicholson, T. W. Girdlestone, Geo. Gordon, Peter Barr, H. Cannell, C. E. Shea, Jas. Walker, Chas. Noble, C. E. Pearson, Hy. Turner, Thos. Baines, Geo. Paul, R. Dean, Ed. Mawley, J. D. Pawle, and the Rev. H. H. D'Ombrian.

Messrs. Jas. Veitch & Sons, Royal Exotic Nursery, Chelsea, exhibited a group of miscellaneous hardy flowering and foliage plants. Amongst the most striking plants in this collection were Rhododendron Rosalie Seidel, some very fine Azaleas, Cytisus scoparius Andreanus, Cercis siliquastrum, Chionanthus retusum, Spiraea confusa, Viburnum plicatum (first-class certificate, see below), Acer palmatum sanguineum, A. p. dissectum, and Lilium longiflorum Harrisii (silver-gilt Flora medal). The same firm also staged a pan of Tillandsia (Vriesia) Leodiensis, for which they were accorded a first-class certificate (see below). For a plant of Phyllocactus Plato an award of merit was awarded (see below). For flowers of Magnolia hypoleuca they were also accorded a first-class certificate (see below). Mr. Perry, gardener to J. C. Tasker, Esq., Middleton Hall, Brentwood, showed a grand collection of Cannas, amongst which such varieties as Paul Bruant, Admiral Courbet, François Corbin, Victor Hugo, F. Benary, Madame Crozy, and Louis Thibaut were particularly prominent (silver Banksian medal). A group of Roses exhibited by Messrs. Paul & Son, Waltham Cross, was one of the features of the Show. The collection included some varieties of recent introduction, such as Clio, Spenser, Crimson Queen, and Zenobia. From the same firm came two boxes of cut Roses, containing some beautiful flowers, notably Salamander, Jean Ducher, Ulrich Brunner fils, Beauty of Waltham, Danmark, Madame Hoste, Grand Mogul, Merveille de Lyon, Medea, Garden Favourite, and Madame Montet (silver-gilt Flora medal).

A group of miscellaneous plants was staged by Messrs. E. D. Shuttleworth & Co., Albert Nurseries, Peckham Rye, which included finely grown examples of Lilium longiflorum Harrisii, Lælia purpurata, Cypripedium barbatum, C. Lawrenceanum, Dracæna Lindenii, Caladiums, and

Coleuses in variety (silver Banksian medal). The same firm also staged a collection of alpine and hardy plants, including Auriculas, Lupinus, Pyrethrums, Narcissi, and Pansies (bronze Banksian medal). From Messrs. Wm. Cutbush & Son came a group of miscellaneous plants, prominent amongst which were Leschenaultia biloba major, Saxifraga pyramidalis, Dracæna superba, Erica Spenceri, E. rosea, E. candidissima, Croton Emile Chantrier, Caladium Charlemagne, Cytisus scoparius Andreanus, and Erica Cavendishi (silver Flora medal). Mr. Chas. Turner, Royal Nurseries, Slough, sent examples of his new Polyantha Rose "Turner's Crimson Rambler"—previously certificated—a grand variety, profuse in flowering and strong in growth; an acquisition to this class of Roses (vote of thanks). Mr. Geo. Mount, Exotic and Rose Nurseries, Canterbury, sent two boxes of cut Roses, in which were very beautiful blooms of Catherine Mermet, La France, Ethel Brownlow, The Bride, Baroness Rothschild, Duke of Edinburgh, Jean Ducher, Thomas Mills, Mrs. John Laing, and Ulrich Brunner (bronze Banksian medal). Messrs. Geo. Paul & Son, The Old Nurseries, Cheshunt, exhibited a charming collection of Rhododendrons and Azaleas. In this exhibit R. Broughtoni, R. Purity, R. Beauty of Cheshunt, R. Sir R. Peel, and R. Duke of Cambridge were particularly striking. A new sweet-scented hybrid variety, the result of a cross between Fortunei and Mrs. C. Butler, named High Beech Hybrid, was very good. The Azaleas were finely represented by Chevalier A. de Reali, Raphael de Smet, Isabella van Houtte, and Comte de Gomer (silver Banksian medal). For a plant of Canna Sophie Buchner the same firm was accorded an award of merit (see below). H. J. Elwes, Esq., Colesbourne, Gloucestershire, staged charming examples of Calochorti (Cyclobothra) in variety. A first-class certificate was awarded for C. amoena (?). This is described elsewhere.

Two boxes of cut Roses were exhibited by Mr. Frank Cant of Colchester. The blooms were magnificent, and included excellent examples of such varieties as Ethel Brownlow, Innocente Pirola, Waban, Ernest Metz, Madame Scipion Cochet, and The Bride (silver Banksian medal). Begonias in varieties were shown by Messrs. Henry Cannell & Son, Swanley. Hector, a double, was accorded an award of merit (see below), as also did R. B. Parsons. A single scarlet bloom was very striking, measuring fully 6 inches across. Mr. W. Gilbert, 1, Albert Terrace, Bishops Waltham, staged charming flowers of Aquilegia Perle Blanche, which were very fine. Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, showed a box of border Carnation Pride of Great Britain. Mr. J. Miller, gardener to Lord Foley, Ruxley Lodge, Esher, sent a plant of Hippeastrum Solandri-florum, which was accorded a vote of thanks. Mr. M. Webster, gardener to A. W. Kirby, Esq., M.D., Kelsey Park, Beckenham, staged a grand group of Myosotis in flower (vote of thanks).

Messrs. P. Barr & Son, King Street, Covent Garden, staged a magnificent collection of flowers (silver Flora medal), including some very fine Pæonies, Irises, Gladioli, Spiræas, Parrot and florists' Tulips, and Pyrethrums. In the boxes of florists' Tulips the following varieties were particularly striking:—Aglaiæ, rose, flamed; Annie Macgregor, rose, breeder; Masterpiece, bizarre, feathered; Modesty, rose, feathered; Mrs. Jackson, byblœmen, flamed; Lord Denman, byblœmen; Dr. Hardy, bizarre; Phillip I., byblœmen, breeder; and Lord Derby, rose, breeder (silver Flora medal). Some plants of Rhododendron Helene Schiffner were exhibited by Mr. J. T. Seidel, Handelsgärtner, Steisen bei Dresden (first-class certificate, see "Awards"). Messrs. F. Sander & Co., St. Albans, sent the new plant Dracæna Sanderiana, and for which a first-class certificate was awarded. M.M. Linden, Brussels, also exhibited a plant, apparently the same as D. Sanderiana, as D. Thalioides var. foliis variegatis, a first-class certificate being likewise awarded in this case. Messrs. Charlesworth, Shuttleworth & Co., Heaton, Bradford, were accorded a first-class certificate for a plant of Bilbergia sanguinea (see "Certificates and Awards").

ORCHID COMMITTEE.—Present: H. J. Veitch, Esq. (in the chair), and Messrs. De B. Crawshay, H. M. Polle, Hugh Low, H. Ballantine, T. W. Bond, T. Statter, C. Pitcher, J. Jacques, E. Hill, W. H. White, H. Williams, J. Gabriel, C. T. Lucas, J. Douglas, T. B. Haywood, F. Sander, S. Courtauld, J. O'Brien, and A. H. Smee.

Messrs. F. Sander & Co., St. Albans, sent a group of Orchids, comprising some choice species and varieties. Among these the beautiful Sobralia macrantha, Aërides Savagena, Odontoglossum Andersonianum hemileucum, O. luteo-purpureum, O. hastilabium, Lælia elegans, Oncidium Roraimensis, Cypripedium Victoriæ Mariæ, C. selligerum majus, and C. Curtisi. Messrs. Pitcher & Manda, Hextable, Swanley, Kent, staged a large collection of Cattleyas, Lælias, Cypripediums, and Odontoglossums, the whole making a charming effect. Lælia purpurata, Cattleya Mossiæ, C. Gravesiana (C. speciosissima  $\times$  C. Mossiæ), and Cypripedium Schröderæ were specially good in this contribution (silver Banksian medal). Messrs. Hugh Low & Co., Clapton, sent Lælia purpurata Lowiana, a grand form (award of merit). Major-General Emeric S. Berkeley, Bitterne, Southampton, sent Dendrobium sulcatum, D. transparens albanum, D. hercoglossum, and Galeandra sp. Mr. Charles Richman, Springfield, Trowbridge, staged a new hybrid Cypripedium named "Chas. Richman." This is a cross between C. bellatulum and barbatum, and the seed was sown in 1889 (award of merit). T. Statter, Esq., Stand Hall, Manchester, staged Dendrobium Bensoniæ album (first-class certificate). E. R. Brooman White, Esq., Arddarock, Garelochhead, Dumbartonshire, sent a variety of Cypripedium concolor. A spray of Bifrenaria bicornis came from the Royal Botanic Gardens, Glasnevin; and C. L. N. Ingram, Esq., Godalming, Surrey (gardener, Mr. T. W. Bond) sent Cypripedium striata, a very pretty species.

Messrs. J. Veitch & Sons, Royal Exotic Nurseries, Chelsea, sent a plant of *Lælio-Cattleya Hippolyte* (*Lælia cinnabarina* × *Cattleya Mossiæ*) and various other plants, which are mentioned elsewhere. An award of merit was adjudged for *Odontoglossum crispum* "De Barri Crawshay," which was shown by De Barri Crawshay, Esq., Rosefield, Sevenoaks, Kent (gardener, Mr. Sydney Cooke). This is described below. Messrs. Charlesworth, Shuttleworth, & Co., Heaton, Bradford, had *Oncidium serratum* and *O. macranthum* Charlesworth var. among other things; and Mr. A. G. Hollington, Forty Hill, Enfield, staged *Cypripedium Evenor grandiflora*. W. F. Darnell, Esq., Devonshire House, Stamford Hill (gardener, Mr. W. Davis), staged a group of Orchids, comprising *Cattleyas*, *Lælias*, and *Odontoglossums*, tastefully arranged with other plants (silver Flora medal). Norman C. Cookson, Esq., Oakwood, Wylam-on-Tyne, had *Cattleya hybrida* Harold, for which an award of merit was adjudged. This is referred to below.

#### CERTIFICATES AND AWARDS.

*Odontoglossum crispum* De Barri Crawshay (De Barri Crawshay).—This is a very fine variety. The plant exhibited had one spike carrying a dozen large flowers. The sepals and petals are white, tinted rose, with reddish brown blotches; the throat is lemon yellow (award of merit).

*Dendrobium Bensoniæ album* (T. Statter, Esq.).—An exceedingly pretty variety. The sepals and petals are pure white, as also is margin of the lip, the other portion and throat being a rich orange yellow (first-class certificate).

*Cattleya hybrida* Harold (Norman C. Cookson, Esq.).—This is the result of a cross between *Cattleya Gaskelliana* and *C. gigas*, and is a very charming hybrid. The petals and sepals are a rosy mauve colour, the front lobe of the lip being a rich purplish crimson, with a yellow throat (award of merit).

*Dracæna Sanderiana* (F. Sander & Co.).—This is a new species from Africa, and it was stated to have been introduced by Messrs. Sander and Co. through Mr. Johannes Braun. When well grown it is obviously a useful stove plant. It is an erect grower with leaves about 6 or 7 inches in length and 1 to 1½ inch broad. The centre of each leaf is dark green covered with a silvery gloss, the margins being cream coloured. The stems are similarly variegated (first-class certificate).

*Cypripedium Charles Richman* (Mr. C. Richman).—This is a hybrid, the result of a cross between *C. bellatulum* and *C. barbatum*. The dorsal sepal is a dull pink shade, greenish in the centre with dark veins. The petals are similarly coloured, covered with small dark spots. The lip is a dark purplish brown (award of merit).

*Lælia purpurata* Lowiana (Hugh Low & Co.).—A charming variety, with pale rose coloured sepals and petals, and very dark velvety crimson lip (award of merit).

*Dracæna Thalioides* var. *foliis variegatis* (MM. Linden, Brussels).—To all appearance this is the same species as *D. Sanderiana*, described above. A statement shown with the plant read as follows:—"This *Dracæna* was discovered in 1888 by Mr. Braun in the Cameroon (Africa), and sent to the Imperial Botanic Gardens of Berlin. This is the original plant collected by Mr. Braun" (first-class certificate subject to its being correctly named).

*Ulmus Ureedi aurea* (Mr. W. C. Leach).—A rich golden coloured tree, the foliage being of a bright yellow and serrated edges (first-class certificate).

*Magnolia hypoleuca* (James Veitch & Sons).—A pretty species with pure white flowers, which have crimson centres and are fragrant (first-class certificate).

*Tillandsia (Vriesia) Leodiensis* (J. Veitch & Sons).—An attractive plant with dark green foliage and brilliantly coloured spikes, crimson centres, and yellow margins (first-class certificate).

*Phyllocactus Plato* (J. Veitch & Sons).—A remarkably fine seedling, with large bright crimson flowers (award of merit).

*Bilbergia sanguinea* (Charlesworth, Shuttleworth & Co.).—An attractive plant with scarlet bracts and purplish flowers (first-class certificate).

*Begonia R. B. Parsons* (H. Cannell & Sons).—A double variety with well shaped salmon pink flowers. The plant is dwarf and compact in habit (award of merit).

*Begonia Hector* (H. Cannell & Sons).—A fine double variety with bright crimson flowers (award of merit).

*Canna Sophie Buchner* (G. Paul & Son).—A dwarf growing form with robust foliage and large bright crimson flowers (award of merit).

*Viburnum plicatum* (J. Veitch & Sons).—A charming species with white flowers borne in clusters in dense profusion on the branches. A valuable hardy shrub (first-class certificate).

*Rhododendron Helene Schiffner* (J. E. T. Seidel, Dresden).—This is a fine variety with medium-sized pure white flower (first-class certificate).

*Cyclobothra amœna* (H. J. Elwes, Esq.).—An exceedingly pretty flower of a rosy mauve shade, the inside of the petals being covered with hair-like filaments. Three dark blotches are noticeable in the centre of each flower (first-class certificate).

*Melon Ingestre Hybrid* (Mr. E. Gilman).—A greenish white fleshed Melon of good flavour. A cross between Hero of Lockinge and Countess (award of merit).

#### THE LECTURE.

At the usual afternoon meeting at the Drill Hall on Tuesday Professor Cheshire delivered a lecture on "How to Solve Chemical Questions Concerning the Soil without the Aid of Chemistry." Mr. G. Paul occupied the chair, and there was a fair attendance.

The object of the lecture was, as the Professor said in his lengthened

introductory remarks, to teach every gardener, whether amateur or professional, what food is wanting from his soil in order that he may add it in the form of a chemical manure. It must have fallen somewhat wide of the mark, however, as the subject is far too large to allow of anything but the most rudimentary principles being acquired from such a discourse as this.

Lengthy references were made to the effect produced by leguminous plants on the soil, and of what material benefit the nitrogen introduced by this class of plants was to the crop next succeeding it. The value of farmyard manure as a food for plants was referred to, and compared to the advantages of using chemical manures, and while acknowledging the undoubted value of the former the lecturer strongly advocated the more extended use of the latter. The discourse was illustrated in a

FIG. 70.—BURCHELLIA CAPENSIS.

simple manner with the aid of a blackboard and some roots of plants in glass jars.

A few questions were put to the lecturer and answered by him. A vote of thanks was accorded to Professor Cheshire for his lecture, and to Mr. Geo. Paul for occupying the chair.

#### BURCHELLIA CAPENSIS.

THOUGH one of the oldest Cape plants grown, *Burchellia capensis* must be classed amongst those that are neglected, for it is comparatively seldom seen in modern gardens. In a few establishments it is still a favourite, and we recently saw some plants of this *Burchellia* that were remarkably beautiful, bearing numerous heads of its brilliant scarlet tubular flowers. It can be grown in a greenhouse, but it is much more satisfactory in an intermediate temperature, a warm conservatory, or the cool end of a stove, as it grows more freely and flowers more abundantly than in a cold house. A compost of light turfy loam and peat with good drainage meets its requirements; and when growing frequent syringing is beneficial. Under ordinary treatment the plants flower in the spring, when their bright blossoms and fresh green foliage have a most pleasing appearance.

#### RHYNCHOSPERMUM (TRACHELOSPERMUM) JASMINOIDES.

THIS is a most useful ornamental climbing plant for the greenhouse or conservatory, and I think a few remarks respecting its culture and general management may probably be of interest to some of your

readers. The charming white flowers are freely produced from the axils of the leaves along the entire length of the young growth and hanging gracefully in loose axillary or terminal cymes are then most effective. The blooms are also very fragrant, filling the house in which they are grown with a delightful perfume.

*Rhynchospermum jasminoides* is admirably adapted for a variety of positions under glass, but I think by far the best effect is produced when grown as a pyramid. One of the chief features respecting the culture of this charming plant is not to subject it to too severe training; indeed, I find the best results are obtained by allowing the young growths to assume a loose condition, as by so doing a much more graceful and pleasing effect is produced. After the plants have finished flowering, enough of the strongest growths should be tied in to make the plants of an even appearance, all superfluous branches being removed, as nothing is gained by overcrowding.

A compost of good fibry loam and peat in equal proportions, with a little sharp sand, will form an excellent mixture for the plant. Liquid farmyard manure, or one of the numerous chemical fertilisers, if applied two or three times a week will prove very beneficial to them during the growing season. Brown scale is particularly troublesome on these plants, but if syringed, say once a week, with petroleum in proportion of a wineglass to three gallons of water, the pest is easily kept in check. —GEORGE PARRANT, *Ashby Lodge Gardens, Rugby.*

## NATIONAL AURICULA SOCIETY.

(NORTHERN SECTION).

THE annual Exhibition of the Northern Section of the National Auricula Society was held in Town Hall, Manchester, recently, and despite the exceptionally early season the Show was a very good one, some well-grown flowers being staged. Mr. T. Lord exhibited the premier Auricula, a fine specimen of Rev. F. D. Horner, a splendid green-edged variety. Miss Woodhead, Messrs. W. H. Midgley, Irving Hind, T. Lord, J. Beswick, and J. Clements secured most of the prizes for Auriculas, and Messrs. G. Thornley, S. Barlow, and J. Beswick for Polyanthuses. Appended are the names of the leading prizewinners and the varieties they exhibited.

In the class for six dissimilar Auriculas (Alpines excluded), Mr. Irving Hind, Halifax, was first with Mrs. Dodwell, Mrs. Potts, Lancashire Hero, Talisman, Acme, and Geo. Lightbody. Mr. Tom Lord, Todmorden, second with Rev. F. D. Horner, Mrs. Potts, Mrs. Dodwell, Geo. Lightbody, Lancashire Hero, and Acme. Mr. W. H. Midgley, Halifax, third with Mrs. Potts, John Simonite, Mrs. Dodwell, Rev. F. D. Horner, Meiklejohn, Geo. Lightbody. Miss Woodhead, of Halifax, fourth. Mr. Geo. Middleton, Prestwich, fifth. Mr. J. Stokes, sixth; and Mr. J. Clements seventh. For four dissimilar Auriculas Mr. Tom Lord was first with Mrs. Potts, Rev. F. D. Horner, Mrs. Dodwell, and Geo. Lightbody. Mr. Irving Hind second with Mrs. Potts, Lancashire Hero, Rev. F. D. Horner, and Acme. Mr. W. H. Midgley third, Miss Woodhead fourth, Mr. Thos. Buckley fifth, Mr. G. Middleton sixth, and Mr. J. Clements seventh. Mr. Simonite was first for a pair of dissimilar Auriculas with Ivanhoe and a seedling. Mr. E. Shaw second with Mrs. Dodwell and Wm. Brocklebank, followed by Messrs. S. Barlow, J. Dickin, and J. Stelfox.

The single classes were fairly represented. Mr. B. Simonite was first for a single green edge with Dr. Hardy, Miss Woodhead second with Talisman, Mr. T. Lord third with Rev. F. D. Horner, Mr. Irving Hind fourth with Prince of Grecns, Mr. B. Simonite fifth with a seedling, and Mr. J. Stelfox sixth, also with a seedling. Mr. T. Lord came first for single plants of a grey edged variety with G. Lightbody, Mr. W. H. Midgley second with A. Meiklejohn, Mr. Irving Hind third with Lancashire Hero. Mr. W. H. Midgley was first with Traill's Beauty in the white edged forms, Mr. Irving Hind second with Mrs. Dodwell, Mr. W. H. Midgley third with Acme; and Mr. Tom Lord fourth with Smiling Beauty. Mr. Irving Hind took premier honours with Mrs. Potts in the class for single plants of selfs, Mr. B. Simonite being second with Raven, third with Miriam, fourth with Melaney, fifth with Dazzle, and sixth with Viola.

In the class for four dissimilar Alpine Auriculas, Mr. J. Beswick was first with Nellie, John Allen, Mrs. Beswick, and Mr. Durnford. Mr. J. Stokes second with Albion, Edith, Mrs. Ball, and Unique. Messrs. S. Barlow, H. Geggie, J. Clements, J. Stelfox, and George Thornley securing positions in order of their names. In the class for single specimens of yellow centred Alpines Mr. J. Beswick won first, second, and third prizes. In class for shaded Alpines with white centres, Mr. J. Clements was first with Exonia. Mr. J. Beswick was second with Mrs. Beswick, and third with The Bride; followed by Mr. H. Geggie with seedling varieties.

For three dissimilar Polyanthuses (black grounds), Mr. Geo. Thornley, Middleton, gained first prize, the varieties being Mrs. Holden, Mrs. Brownhill, and a seedling; Mr. J. Beswick was second with Lancashire Hero, Exile, and Mrs. Brownhill; Mr. S. Barlow third, and Mr. J. Stokes fourth. Mr. Geo. Thornley was again first for three Polyanthuses (red grounds), showing Lancer, Middleton Favourite, and George IV.; Mr. J. Beswick second, Mr. S. Barlow third. Mr. Thornley was also first for a single specimen red ground Polyanthus with Middleton Favourite, and second with Lancer; and Mr. S. Barlow third with Prince Regent. For single plants of black ground Polyanthuses Mr. Geo. Thornley led with Mrs. Brownhill, and second with a seedling; Mr. J. Beswick third with Exile; Mr. Thornley fourth with Cheshire Favourite; Mr. Beswick fifth with Lancashire Hero; Mr. S. Barlow sixth with John Bright;

and Mr. G. Thornley seventh with Mrs. Holden. For twelve dissimilar fancy Polyanthuses, Mr. S. Barlow was also first, and Miss Hopkins of Knutsford second.

Mr. Barlow was awarded a first-class certificate for a seedling Alpine Auricula, Miss Lloyd, a charming variety.

## FRUIT FORCING.

**Vines.**—*Houses of Ripe Grapes.*—Vines started in December will now have ripe Grapes. The temperature should be lower, but sufficient fire heat will be necessary to prevent its falling below 60°, and allow a free circulation of air. Sufficient moisture, however, must be present in the atmosphere to prevent injury to the foliage from drought or the spread of insects. Examine the borders, and if sufficiently moist let them be covered with a little short litter to prevent evaporation and keep the soil from cracking. Vines carrying ripe Grapes in June and July require more water than they do in the autumn. If water is necessary afford it in the early part of a fine day, keeping the soil healthfully moist. Allow a moderate extension of the laterals, which will keep the roots active, and prevent the foliage ripening prematurely. Shading will be necessary to assist the Grapes retaining their colour longer, as ripe Hamburgs lose colour when exposed to the direct rays of the sun for some time, which must be prevented by placing a double thickness of herring nets over the roof lights.

*Houses Started at the New Year.*—The Grapes will now be advanced in colouring, and require a free circulation of air. Moderate atmospheric moisture will still be necessary for the benefit of the foliage, and it will not injure the Grapes, provided it is not stagnant and deposited upon them. A little air and gentle warmth in the hot-water pipes will keep the atmosphere in motion and prevent moisture being deposited on the berries. The borders must not be neglected for water, but when needful afford a supply to keep the soil in a moist condition. Allow the laterals to extend where there is space, as a good spread of foliage aids the retention of the colour in black Grapes. Where red spider has obtained a hold prompt measures must be adopted for its destruction. Sponging the leaves is a safe and efficacious means of preventing the spread of the insects. Sulphuring the pipes sometimes proves worse than the pests, as an excessive dose prejudicially affects the skins of the Grapes, but a judicious application of sulphur, mixed with skim milk, to the hot-water pipes, heated to 170°, on a calm evening, and with the house closed, destroys red spider without damage to the Grapes. The heat should be maintained about an hour, and then it may be allowed to fall to the ordinary temperature. Where fermenting material on outside borders has become cold and wet a portion of it must be removed, leaving enough for a light mulch.

*Early Muscats.*—Those started in December to ripen early in June are just beginning to colour. They require a moist condition of the soil, as the berries are liable to shrivel unless the Vines are kept well supplied with water at the roots. When beginning to colour Muscat of Alexandria is liable to be scorched, for which a slight shading of herring netting doubled is a good preventive, but early ventilation and a circulation of warm air must be attended to. This will cause the Grapes to be a little later in ripening, but well-ripened Muscat of Alexandria cannot be had before the middle of June. Black Muscat and Madresfield Court may be had much earlier and with less heat than is required for Muscat of Alexandria.

*Succession Houses.*—Disbudding, stopping, tying, and regulating the growths must be followed up, making the most of the space at command for a good spread of foliage fully exposed to light. Allow crops proportionate to the vigour of the Vines, removing surplus bunches before they come into flower. Examine the borders occasionally, and when dry afford a thorough supply of water. Vines in full foliage and carrying heavy crops of fruit should be assisted with surface dressings or liquid manure. Inside borders will take almost any quantity of water, provided they are well drained, when the Vines are swelling their crops. Outside borders in this exceptionally dry season, and where high and dry, will require a copious supply of water or liquid manure. Ventilate early; it causes accumulated moisture to disperse, gives texture to the foliage, and solidity to the wood. Allow a high day temperature from sun heat, closing early to store the sun-warmed atmosphere. A temperature of 60° to 65° at night is best, especially to Vines carrying heavy crops, which require more time than those but lightly cropped, and maintain a day temperature of 70° to 75° in dull weather with a little ventilation.

*Grapes Stoning.*—This process requires time and a steady temperature, 60° to 65° at night being sufficient, and 5° to 10° rise by day artificially. The borders must be kept well supplied with moisture, but excessive supplies of water and feeding substances check root-action and induce shanking. Keep the pinching of the laterals well in hand, avoiding checks, either by large reductions of foliage, cold currents, or water supplied at a low temperature. When the stoning is completed feed liberally, maintain a good moisture in the house, and mulch the

border lightly. Afford a gentle circulation of air constantly, increase it early in the morning with advancing sun, and reduce correspondingly with the declining sun heat, closing sufficiently early to retain a good heat.

**Late Houses.**—Attend to stopping and tying, laying in laterals as the space admits without crowding. Thin out the berries liberally, reserving the best set and most compact bunches for the crop, as these finish better than large loose ones. Top-dress the borders according to the vigour of the Vines. If young and strong they may only need a light mulching, or if the soil is light cowdung will be found more beneficial than stable manure. In some cases the late Vines will only be in flower. Lady Downe's, Mrs. Pince, Black Muscat, Alnwick Seedling, and other shy setters should be cross-fertilised, using pollen from Ham-burghs and Alicante, operating on fine days.

**Cucumbers.**—Be careful that the plants do not suffer through insufficient supplies of water, always applying it at the same temperature as that of the bed. Plants in bearing all the winter will now be showing signs of exhaustion, and had better be removed and their places filled with young plants without delay. Assist young plants which show signs of weakness by removing the male flowers and the first fruits, stopping at every third or fourth joint, removing all weakly and superfluous growths. Shading will be necessary for an hour or two in the middle of the day when the sun is hot, especially houses facing south, but shade only to prevent flagging. Little fire heat will be required by day, shutting the valves at about 8 A.M. and opening them again at about 4 P.M. or later. Maintain a good moisture by damping the floors two or three times a day. If aphides appear fumigate on a calm evening and repeat early the following morning, leaving the foliage dry but the floors well damped, especially when there is white fly. That pest and red spider are best eradicated by removing the worst infested leaves and brushing the hot-water pipes when hot with a thin wash of sulphur and skim milk. Keeping the evaporation troughs charged with liquid manure or sprinkling the floors in the evening with it is beneficial.

Sow seeds for raising plants to occupy pits and frames as they become cleared of forced vegetables and bedding plants. A moderate bottom heat may be secured by using the less decomposed material from Seakale, Vine borders, or spent hotbeds, which, with about a fourth of fresh material, will afford all the bottom heat now required. Attend to renewing the linings, and still employ good night coverings. Close early in the afternoon, and so as to run the temperature up to 90° to 100°.

**Melons.**—Train the shoots thinly, never permitting them to become crowded. Keep the atmosphere dry and well ventilated when the fruit is setting, and fertilise the flowers, so as to have three to half a dozen fruits of about an equal stage of swelling on a plant, being careful not to allow one fruit to take the lead. Stop the shoots one joint beyond the fruit. Place supports to fruits becoming heavy to relieve the vine of the weight. Attend to stopping the laterals after the fruits are swelling, maintaining a good moisture by syringing the walls as well as the foliage at about 3.30 P.M., and damp the floors in the morning and evening, or oftener in hot weather. Water or liquid manure will be required about twice a week. Maintain a night temperature of 70°, 75° by day from fire heat, and 85° to 90° with sun. Ventilate early and freely, but avoid admitting too much at a time with a view to lower the temperature, commencing to ventilate at 75°, and increase or diminish it according to external influences. When the fruit commences to ripen gradually reduce the supply of water at the roots, but not so as to cause the foliage to flag, and afford a circulation of warm rather dry air, the temperature being maintained at 70° to 75° by artificial means, and 80° or 90° with sun heat. Cut the fruits before they are dead ripe, and keep them until in good condition—evenly ripe all over—before sending to table. Cracked fruits arise from various causes—generally by a deficiency of water when swelling, and a close atmosphere, with too much water at the roots when ripening. The remedy is to diminish the supply of water to the roots, admit air constantly, and cut the shoots about half-way through with a knife a few inches below the fruit.

Encourage plants swelling their fruits by syringing freely in hot weather at closing time, damping the floors when they become dry, and sprinkle them in the evening with clear liquid manure, say 1 lb. of guano to 20 gallons of water. Ventilate freely in favourable weather, commencing from 75° to 80°, increasing or decreasing it according to external influences, maintaining a day temperature of 80° to 90° with sun heat, and closing between 80° and 85°, always so as to run up 10° or more, which will increase the size of the fruits and lessen the necessity for fire heat at night, but it must be accompanied by plenty of atmospheric moisture. If thrips appear fumigate moderately on two or three consecutive evenings, and repeat in a week afterwards. Red spider may be kept under by syringing, or coat the hot-water pipes lightly with flowers of sulphur. If canker appear rub quicklime well into the affected parts and repeat as necessary.

**Pits and Frames.**—Train out the growths, keeping them rather thin. Attend to setting the blossoms in bright weather, and pinch off the points of the shoots at the same time one joint beyond the fruit. If there is any difficulty in getting the fruit to set, apply a good lining to the bed, and admit a little air constantly, withholding water. Shade only to prevent flagging. Plants swelling their fruits should be well earthed, the laterals pinched and thinned out, and the fruits raised on pieces of slate on inverted flower pots. Sow seed to raise plants for planting in frames after they become cleared of bedding plants, potting the young plants when they show the second leaves, and take out their points at the second rough leaf.

## THE KITCHEN GARDEN.

**Runner Beans.**—If a good sowing is made now the seed should germinate quickly and strongly, and the plants will most probably escape injury by late frosts. If wanted extra early from a week to a fortnight may be gained by sowing the seed singly in 3-inch pots in gentle heat, and planting out before the seedlings become root-bound. These Beans also transplant readily out of pans or boxes, and this should be done by those who find their first sowings are coming up badly. In every case a rich and deep root-run should be provided, as they are liable to collapse during a hot and dry season unless abundantly provided with moisture and good food at the roots. If the ground has not been trenched recently, and is not of a heavy binding nature, open a trench or trenches 2 feet wide and a spit deep, fork a heavy dressing of manure into the bottom spit, and return half of the soil first thrown out on to the top of this, making all fine and firm. Water if at all dry, sow the seed thinly, cover with 2 inches of the loose soil, and bring the rest of the latter up to each side of the row in the form of a basin—this facilitating watering operations later on. Seed may also be sown on well manured, ordinarily dug ground, that has been sufficiently long broken up to crumble to pieces freely when watered, or after a soaking rain. Before arranging the rows it ought always to be decided how the plants are to be staked. Stakes of almost any length may be used, those about 8 feet in height being the favourite size. If arranged in a single line the rows ought to be not less than 6 feet apart. Double rows are often preferred, the stakes crossing each other 18 inches from their tops. In this case sow the seeds thinly in two drills 12 inches apart. The crops in the open fields are not staked, all running growth being pinched off the plants as fast as they form, but this plan does not, as a rule, answer well in the more sheltered private gardens. If tried sow the seed thinly in drills not less than 3 feet apart.

**Cropping between Beans.**—Where a considerable number of rows of Runner Beans have to be grown, and these are given the good room they ought always to have, the intervening spaces should also be turned to good account. Early Potatoes, two rows of these being planted near the centre of the 6 feet spaces, are about the best crop that can be recommended for this purpose, and it is not yet too late to plant these. Cabbages, Cauliflowers, Lettuces, and Turnips are other crops that would succeed, and come off the ground before the Beans would shade it badly.

**Dwarf Kidney Beans.**—After Runner Beans have become plentiful there is only a light demand for Dwarf Kidney Beans. It is early in the season that the latter must be forthcoming, and fortunately it is then when they usually thrive, and produce the best gatherings of straight tender pods. With the help of pits, frames, and handlights, the two former being previously occupied by Lettuces, Potatoes, or other early crops that required heat to forward them, good pods may be obtained. There is a considerable gain by raising the Kidney Beans in heat and planting in the frames or handlights, the precaution being taken not to crowd the plants. If not already done more seed of Sion House, Ne Plus Ultra, or other early varieties should be sown on a warm border in drills 18 inches apart and 2 inches deep.

**Peas.**—Those planted out from pots and boxes and such like are not doing well this season, the majority flowering prematurely. These neither require nor merit staking, quite as good crops being had by allowing them to fall on the ground. If dwarf varieties have been put out 2 feet or rather less apart sow rows of early or second early Kidney Beans midway between them, while any put out 3 feet or more apart may have two rows of Beans sown or planted between them. When the Peas are cleared off the ground give the Beans a good watering if at all dry, then mould them up, and no further trouble will be necessary with them. They will well repay for the room if the Peas do not.

**Vegetable Marrows.**—If these are wanted early great square heaps of all kinds of decaying vegetable refuse, leaves and manure answer well for the purpose, the plants being put out now either under handlights, glazed frames, or any makeshift form of protection. Give them a little good soil to start in, and be not over-lavish with the plants or they will quickly over-run and smother each other. Three plants are enough for a ridge 6 feet square, and even these must not eventually be confined to this space, or they will fail to bear well. It is a mistake to raise the plants long before they can be planted out, as they soon become badly starved and stunted. All such may well be thrown away and fresh plants raised singly in 3-inch pots in gentle heat, taking care to get these finally planted before they become much root-bound. In the warmer parts of the country the market growers' method of culture answers best, the plants in this case forming a minimum amount of haulm and producing most abundantly. Select a somewhat sheltered yet open spot, open a trench running from north to south 4 feet wide and one spit deep, spread over the bottom a thickness 9 inches deep of good decaying farmyard or stable manure, and on this return and level so as to completely enclose it, the soil previously thrown out. Either sow about three seeds in patches 3 feet apart through the centre, or raise plants at once and turn out singly at that distance apart, protecting in either case with inverted flower pots or other contrivances during cold nights.

**Ridge Cucumbers.**—These can be treated in nearly every respect similarly to Vegetable Marrows, as they succeed equally well in the open as on heaps of manure. They require rather less room though, and stand in need of more shelter from cold and twisting winds. Enclosing both Marrows and Cucumbers by thatched hurdles is labour well expended.

**Sowing Seed in Dry Weather.**—There must not be long

intervals, or more than two or at the most three weeks between the sowings of Lettuce, or there will be a gap in the supply; transplanting also being resorted to now as little as possible. With Peas again it is not advisable to wait long for rainfall before making successional sowings—a good rule being to sow more seed when that last put in has germinated. If the ground is dry, hard, and lumpy give it a good watering at night, and it will then break to pieces easily the next morning. Should the soil be fine but the drills dry when opened give these a watering prior to sowing the seed, and cover in with the dry soil. This will be found a much better plan than watering after the seed is sown and the ground levelled. Planting in dry soil is also a mistake, the better plan being to well moisten both the ground and the plants to be moved a few hours prior to cropping it.

## THE BEE-KEEPER.

### APIARIAN NOTES.

FROM some places we hear reports of full supers, and as many as two taken from one hive of Punics. With us the bees had not the means of gathering more than what will tide them over till the Clover season. As I hinted last week unless full breeding space is afforded the seeming abundant early yield of honey will tend to loss rather than profit.

In no case have our bees been supplied with artificial aid since January, and that was very limited, yet all are in a very forward condition and may swarm at any time now. Up till the last week of April the nights were often frosty, and where supers were put on they cooled the hives, and breeding was somewhat retarded. The supers are not first class, and the honey would have been better stored in the body of the hives which ought to be larger than the majority of bee-keepers use. A large hive is not so inimical to the prosperity of the bees as supers, unless they be small, at this season of the year.

Although everything is promising at present, and the bees are in readiness, we do not know what is in store for us; we may have a continuation of fine weather or the reverse. My plans are, if goes well, to let my hives increase a fifth, and to raise nuclei in excess the number of stocks to be kept. With the early season it is probable, should fine weather continue, that they will make an attempt to increase 250 per cent., but this will be checked by one or more of the modes of restriction previously mentioned. On no account should the destruction of surplus queen cells be neglected, nor longer than the eighth day after the first swarm issues. There are exceptions to that rule. Frequently the prime swarm issues with a young queen, the old one may accompany her or be left in the hive for future disposal by the bees. It is, therefore, advisable to examine the stock hive immediately after the issue of the swarm, to ascertain the advanced state of the queen cells. It is an easy task to destroy cells, but a difficult one to depose all the queens that may be free in hives of that nature. Amongst the many methods for swarming there are none so simple and so easily performed as the one just described.

#### JOINING SWARMS.

There are various ways of disposing of bees to prevent an increase and to keep the stocks strong, such as joining two or more swarms, and adding the combs of one hive to another. One plan I was successful with in years gone past was to hive the swarm, set it close by the side of the stock hive, or in front of it, and sometimes upon the top of it, as circumstances demanded, until it was settled and working. As soon after that as possible I transferred some of the combs, with a portion of bees, from the stock hive to the swarm, as well as the supers. Sometimes I put the swarm uppermost, and at others beneath the stock; when uppermost I turned the stock's entrance either to the back or the side. In my Lanarkshire extension hive for two queens the entrance was mostly at the side, with the perforated zinc divider between the two, but for obvious reasons this was only put in several days before uniting, the close-fitting divider being employed at first. With storifying hives, with a swarm above or below, the zinc divider took the place of the floor two days previous to uniting, when the old queen was deposed and the young one fertile.

This plan put an end to swarming. All the working bees continued to gather honey with greater vigour, as all swarms do, than the unswarmed old stock, while the nucleus left insured the prosperity of the hive for another year. My hives with these arrangements were shown at the Caledonian Society 1875 and the three following years. In the "Farmer" and other papers in 1878 the late Mr. Wm. Raitt styled it the "wonderful hive." I mention this fact because at the present time so much is said about so-called "new" systems which are really old.—A LANARKSHIRE BEE-KEEPER.

••All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Violas (W. B.).**—It is doubtful if an "exact" distinction between Violas as commonly grown and Pansies can be given in a few words, as Pansies are Violas, but all Violas are not Pansies. If any expert can draw a well defined line between them we will readily publish his achievement.

**Violas (John Forbes).**—The box of blooms only arriving as we are preparing for press, it can only be said that the flowers, in great variety, are remarkably good considering the unusual term of bright dry weather to which the plants have been subjected. You evidently possess a very fine collection.

**Carpet Bed Designs (J. M. Stone).**—Mr. A. Graham, Garden Superintendent Hampton Court Palace, Kingston-on-Thames, published a small manual a few years ago containing a variety of good designs for planting carpet beds. You might write and ask him if it is still in print. We do not know of any other.

**Alpine Honeysuckle (Querist).**—There are several so-called "alpine" Honeysuckles, but one of the most distinct and pleasing is *Lonicera pyrenaica*, forming dense dwarf twiggy bushes 6 to 18 inches high, the flowers being borne in clusters, ivory or creamy white in colour. It requires rich loamy soil in well-drained but moist narrow fissures of rockwork, with an open exposure.

**Grapes Rusted (A Subscriber).**—The leaf "infestation" is simply an exudation of sap in the form of globules which have dried. The leaves are rusted. The condition of both leaf and fruit suggest that the temperatures and ventilation have not been properly regulated. There has been a mistake somewhere, but it is impossible to describe it with exactitude in the absence of particulars of your routine.

**Early Peas (H. Witt).**—The pods of Suttons' Ringleader, gathered on May 6th, are good and well filled, and we are not surprised to learn they are three weeks earlier than last year. It is impossible to insert letters written on both sides of the paper when they arrive as we are making up our pages for press. Matter for publication should be written on one side of the paper only—always, and by everybody.

**Eradicating "Dutch Elder" from a Lily of the Valley Bed (Querist).**—The only effectual method is to take up the Lily of the Valley in the autumn as soon as the leaves have died down, and thoroughly remove every particle of the creeping roots, and then replant, taking care not to introduce any part of the weed with the Lily of the Valley roots. The weed may be considerably weakened by cutting the crowns off as fast as they appear.

**Preserving Fruit and Vegetables—Market Prices (St. Julien).**—Certainly the writer to whom you refer had in view establishments of considerable size, in which fruit and vegetables are grown and prepared for commercial purposes, and you did not intimate that your establishment was a small one. It is questionable if what you have in view could be likely to be profitable on a small scale. We will make further inquiry into the matter. You are in error in your assumption that our market returns are "not revised for months." They are revised every week in the market, and are founded on actual average returns. The example you quote does not in the least represent average sales, but the returns of expert growers. These no more indicate the average than the prize animals at a Smithfield Show represent the flocks and herds (including the starvelings) in our pastures. To regard the list to which you allude as anything near the average would be utterly fallacious and misleading. It seems to us that you require something different from real average prices, but have not explained what it is, and perhaps it would not be easily explainable. If your returns are so much higher than those published all the better for you, and the more creditable to your skill as a cultivator.

## OTHER LANDS.

NOTWITHSTANDING it has ever been the policy of this Journal to preserve for itself the character of being eminently practical, there have nevertheless been occasions when it has not hesitated to admit matter of a more general and descriptive nature did it appear likely that this might indirectly conduce to the welfare of its readers. Emigration is a question which nowadays touches the interests of persons of every class more nearly than it used. Partly on account of the increase of population in these Islands, partly on account of the greater facilities of travel, and chiefly, perhaps, on account of the wide-spread diffusion of information through the Press, the eyes of dwellers in even retired districts turn without any of the old-fashioned feeling of dread in the direction of regions half-way across the globe.

When one thinks of the reluctance with which emigration was regarded until within the last thirty years by the mass of the inhabitants of Great Britain, it is difficult to understand how the British race has become so widely extended as we see it now. The Irish Potato famine certainly acted as a drastic measure for promoting emigration from the sister isle. Previously to that visitation the area of Greater Britain was extended mainly by haphazard recruitment from the country districts of England and Scotland. Restlessness or necessity drove individual units abroad, and these, by their private reports, drew their friends and relatives after them.

For the last fifty years, however, the Press, either in the form of books of travel or of newspapers, has been the main instigator of emigration. A large accession to the ranks of American emigrants, too, may reasonably be attributed to the songs of Henry Russell and the novels of Mayne Reid. Now, as we may see in any perusal of a daily paper, the incitements to quit the home of one's birth abound, and it is often a difficult matter for an intending emigrant to decide upon a destination in the face of the various and glowing pictures held out by competing syndicates and colonial governments. Inasmuch as there is a general conspiracy on the part of the promoters to procure population at all costs, successful speculation in *sparsely peopled* land being impossible, it often happens that emigrants are misled by unscrupulous misrepresentations, to their disappointment or absolute undoing.

It cannot be denied that, despite the prosperity of these islands, the conditions of life are rapidly altering and making the existence of a large rural population impossible. The industrial stage of social development is opposed to small holdings, and the more England becomes the industrial and commercial centre of the world, the more futile will the efforts to restore the class of small cultivators appear. Economical tendencies are all the other way. There are, however, two portions of the globe in which the small cultivator seems destined to enjoy an exceptional future, and these are New Zealand and California. In some measure the same may be said of Tasmania and parts of Australia, though scarcely in so great a degree. As it is possible that there are among our readers many young men associated with gardening and fruit culture who are contemplating emigration, it has occurred to the writer that the experience of some twelve years spent in California and the Australasian colonies might not be unprofitably communicated. It must, however, be stated that in penning these notes the writer desires to repudiate all intention of exciting false hopes.

Emigration is a lottery, and it is well to set out with moderate

expectations, or even the mere expectation of earning a comfortable subsistence in lands of genial climate and easy social conditions, than with visions of shaking the Pagoda Tree or "striking" a Comstock lode. Now, as aforesaid, there are fortunate exceptions in the ranks of emigrants whose luck is blazoned as a misleading beacon; but these serve only to prove the rule that to the vast majority emigration means nothing miraculous in the way of success. To the unmoneyed man it means expatriation for life, as few persons going without capital become speedily rich; and by the time competency has so crowned the settler's efforts as to enable him to revisit his native land the old folks have passed away, and a young generation has arisen to whom Joseph is unknown and not particularly interesting. But there is consolation; for as soon as the novelty of sightseeing here is exhausted the emigrant longs to be off to his new — his only home, again, where lie the true hearts and the more congenial surroundings which, unbeknown to himself, have become essential to his happiness. The sentiment for "Old England," or "Home" as it is always called wherever the English Flag waves, is still very strong, and extends to colonists who long in vain from childhood to old age for a glimpse of the Mother of Nations; but the conditions of life are too restrained here to be long palatable to any but those who have left England after their minds have been thoroughly moulded.

The first effect of opening up the new lands of America and Australia was to show their enormous capacities for the production of wheat and live stock, and there began the development of communities based upon pastoralism and a wasteful and primitive agriculture. Within the last twenty years, however, the capabilities of certain portions of these regions for the close cultivation of fruit have been becoming more apparent. There are signs, indeed, of the advent of a new era when the supply of temperate fruits will be perennial here, those of the southern hemisphere coming in at the close of the winter to continue the succession as the stock drawn from the northern hemisphere gives out. The time of its establishment depends merely upon the improvement in the speed of steamers and their adaptation to the safe carriage of such perishable cargo as fresh fruit. Once it is realised in South Africa, Australasia, and Argentina that there is an unlimited market for fresh and dried fruits in Europe, a renewed stimulus will be given to production and exchange in those at present desponding and depressed lands. Even now a remarkable advance is noticeable upon the conditions prevailing in the fruit industry thirty years ago, the periods for subtropical and tropical fruits being much more prolonged than formerly. It is, therefore, not only possible but highly probable that before one generation has passed Londoners will be able to buy Grapes, stone fruits, Apples, and Pears in late winter and early summer at almost the same rates as they are sold in Spain and France during the height of the season.

Southern Europe has no longer a monopoly of the trade in those fruits of which it has hitherto been considered the seat. The culture of the Orange and the Lemon is now developing rapidly elsewhere. In California the Citrus zone is yearly extending from the centre of Los Angeles in the south, and were accessibility to as inexhaustible a market as that possessed by California apparent to the people of New South Wales, Sydney would soon become the centre of as great an industry. Indeed, there is nothing in the way of sub-tropical fruits which Australia cannot grow with as great prodigality as California did she only enjoy the advantage of having as fine a market at her doors, while her extension for these purposes is three-fold that of California, or equal to the whole of Southern Europe. There are, however, four countries which offer exceptional advantages to an English emigrant who would combine the pleasures of life in Andalusia with those of his own home, who would in short enjoy what is best in the climates, the fruits, and the flowers of that portion of Europe extending from the south of England to Sicily. These four countries are New Zealand, Tas-

mania, California, and Oregon. I place New Zealand first of these in spite of the vigorously "blowing" of the Californian (who, by-the-by, is the most blatant "blower" of the most eminently blowing citizens of the U.S.A.). In season and out of season does the Californian "blow," awake and asleep; each day of the week, each week of the month, each month of the year does there issue from the Press of California an unfailing stream of literature glorifying the "Golden State" and recapitulating its *ree*-markable *ree*-sources. If you wish to irritate a Californian merely chant the praises of Oregon, her neighbour State on the north, where, says the Californian scornfully, it rains thirteen months in the year. The Oregonian, on the other hand, tells you that if your future is uncertain and you wish to become "acclimated to infernal fire, sir," go to the Mohave Desert in Southern California.

The truth lies between these extremes. Oregon is a very beautiful State, to an English person perhaps more beautiful than California, being more like the north of France and Belgium, while California resembles rather southern France and Spain. The fact is the two together comprise what is best in the whole of the United States in respect of genial climate and extraordinary productiveness. Why the inhabitants of California should "blow" so much more than those of Oregon it is not easy to say, for though the climate of California is more favourable for delicate persons, it is too dry for the encouragement of that perennial verdure which is so pleasing to the eyes of English people. While it is an absolute paradise of grass and flowers during the months of March and April, it has for the rest of the year a very brown and dried-up appearance. Bret Harte describes it as the land of a "spring which obtains but one month of the year;" consequently, despite the not unjustifiable boasting of the Californian, I should say that a robust English person would find Oregon a more congenial place of settlement, as being more like his own home, just as he would prefer New Zealand or Tasmania to Australia, or the neighbourhood of Orleans to that of Marseilles.

But if Oregon rather than California is the land of the Apple, the Pear, the berry, and the prunous fruits, she entirely cedes place to the latter in respect of wall fruit and in the matter of Grapes, Almonds, Oranges, Lemons and Figs. As the two countries lie direct north and south there is a neutral zone about the frontier line over which a common climate reigns and in which the same fruits can be successfully grown. Thus at Jacksonville in Southern Oregon the Grape and the Peach mature well, while in Shasta county in Northern California Apples and Pears of very good flavour and great size can be produced. As regards the fruits of the colder portion of the temperate zone California has indeed the advantage, for the Sierras run throughout her length, and upon their foot-hills and slopes a Devonshire climate prevails during summer in latitudes where the great valleys or plains below lie blistering in the heat of Campania or Provence. Similarly along the coast for a distance of seven hundred miles run the coast hills within reach of the sea breezes, and over this strip there reigns a climate of eternal spring. In it are situated those health resorts which are fast becoming more popular among persons of delicate constitutions in Europe as well as in Northern America. In fact California has three zones of climate—the vernal zone of the coast hills, the hot zone of the central valleys, and the alpine zone of the Sierras. Hence her capacity for fruit-growing is not only great but varied, and she makes it a matter of pride that she can grow anything from Gooseberries or Blackberries to Bananas. This is true, but as might be expected much of these are mediocre in quality, and in her especial lines more sober Oregon can surpass her gay, boastful, and bounteously endowed sister State.—M. H.

#### HARDY FLOWER NOTES.

"A GOLDEN spring," such are the words which might well be inscribed in illuminated letters on the garden record of the year. Worthily they may be applied, for never has my garden given so

much pleasure and such wealth of beauty. Alloy there may be in the gold, but there is only sufficient admixture to give piquancy to the pleasure, and at no time since the hard winter days passed away have we had cause to complain. Even the east winds, less prevalent than usual, have had their unwelcome force and fury subdued; and did they for a time muster their forces to assail the beauty of the flowers, their fury was of briefest duration, dying away in softest breathings and gentlest whispers, as if pleading forgiveness for the rude assault. Thus, though comparatively little rain has fallen, the earth has not been robbed of its moisture, and the flowers have enjoyed to the full the gracious season. Thus it is that one is reluctant to move from the precincts of the garden to take up pen even in praise of the flowers, feeling that at such a time what is written in the house may present the mustiness of the herbarium or the flower lover's library, instead of breathing out to some extent at least the freshness and life of the flowers themselves. But there are practical inconveniences which stand in the way of writing amid the flowers, and we must tear ourselves away and solace ourselves by sitting where uplifted head will disclose some at least of their blossoms. Short as they come of the more cultured grace of the English florists' Tulips so recently spoken of, the Dutch varieties show by their beauty that they, too, are of patrician race, although their markings are inferior to those of the flowers which have been the pride of our insular Tulip lovers. Beautiful as they are they lead one to long for some of these English kinds, not perhaps to be grown under a canvas tent, but to be a crowning pride to the hardy flower garden, where nothing is too choice to enter, and where beauty in its highest form should find admission.

Looking, then, at the Tulips of the garden, which have enjoyed the unwonted calmness of the season, moving slightly in the gentle breezes so markedly in contrast with the usual gales, which here, to our dismay, at times snap off the heads of these flowers, we cannot but remark upon the superior grace and beauty of the single flowers as compared with the double forms. Useful as the latter may be for bedding purposes, they are in many ways inferior to the others for the garden of hardy flowers where the Tulip is seen at its best with the setting of greenery afforded by the springing growth of the later herbaceous flowers. Even the commoner early-flowering Tulips of self, or almost self colours, give us rich tints of crimson, of gold, of blush pink, or of ivory white, and when we come to the natural species we have much of interest, apart from their own intrinsic beauty. We have spoken of some of these before, and may again speak of some in more detail, but a species which has of late been more sought after, and which is likely to be increasingly admired, deserves at least a passing notice. This is *Tulipa vitellina*, which in ordinary seasons flowers late in May, but which has this year been in flower from about the middle of April. It opens of a delicate sulphur yellow flushed with green, and passes off to almost creamy white. It is about 2 feet in height, and though no "fop of the parterre," is extremely attractive. I believe it is a true species, but can find no information about it, as the compilers of our ordinary works of reference make no mention of the plant.

Of more lowly stature, yet of choicest beauty on rockwork or trailing over the stone edging of some of the borders, are the dwarf Phloxes, which form such beautiful mounds of flower as to be universally admired. To the ordinary observer they scarcely seem Phloxes, so widely are they removed in appearance from their autumn flowering congeners which, with equal or greater splendour, make our gardens gay.

The awl-leaved section, as represented by the varieties of Phlox setacea or subulata, are much admired with their spiny tufts of foliage and profusion of bloom. Is *P. setacea* synonymous with *P. subulata*? There seems to have been some difference of opinion on this point, but for garden purposes minute distinctions are of little consequence, and we may adopt the classification of the nurserymen and treat them as practically the same. It is unfortunately true that some of our newer varieties, for some of which we are indebted to the late Rev. Mr. Nelson of Aldborough, are not so hardy as others, and require protection in some localities. This may perhaps be avoided by planting in selected positions, and I have generally found that an eastern aspect protected from much wet in winter is a preferable one. One of the brightest, which is, unhappily, a little tender, is *P. s. Vivid*, with small flowers, but of really "vivid" crimson colour. Two others which have up till now proved a little tender here are *P. s. Perfection* and *P. s. pallida*. This, however, cannot be said of *P. s. atropurpurea*, which is one of the most useful of all, never failing to grow and flower well every season, giving with its pretty crimson purple flowers a pleasant aspect to the spot it occupies. Seemingly, too, one of the hardiest is *P. s. Nelsoni*, worthily named in honour of one of our lost horticulturists, with very beautiful little bushes of white flowers. A very beautiful little plant also is *P. s. The Bride*,

with pretty flowers with a tinge of pink at the eye, which feature is, we may suppose, the origin of the name, being supposed to represent the blush of the bride. Other varieties of the section might be mentioned, but we are unwilling to leave *P. stellaria* and *P. stellaria* G. F. Wilson, both of which are very beautiful, with more diffuse and spreading habit than the subulata varieties, forming, indeed, in some soils what an eminent grower of hardy flowers described to me as what may be likened to "torrents" of foliage all spangled over with starry flowers of white or lilac. *P. reptans*, known also as *P. verna* and *P. stolonifera*, is so well known as to need little mention, but one of a similar character though much superior may well be sought for. This is *P. amoena*, which, when in full flower, is certain to give satisfaction to the grower, with its somewhat villous leaves and masses of purple or pink flowers. Several other species and varieties would call for notice, but as other flowers have equal claims they must be left to another time.

The cultivation of these alpine Phloxes presents little difficulty where the climate is suitable. In my garden, with the exception of those here noted, they prove long livers, and give no trouble in light sandy peat, the awl-leaved section and the varieties of *P. stellaria* being grown over stones. They have, however, their enemies in the shape of snails and slugs, which are particularly fond of the flowers and leaves, and will, unless searched for, destroy the bloom of the season.

The Wallflower is always acceptable in our gardens, its sweet perfume and pleasing colours giving much true pleasure. This last winter has, however, been a fatal one, and few of our plants have been left to supply cut flowers or to brighten the borders. Singularly enough, however, the Cheiranthi or alpine Wallflowers have suffered less than usual, and have formed charming objects on the top of a rockery protected from the biting north winds by an old wall. Here the pleasing canary-coloured blooms of *Cheiranthus alpinus* are the observed of all, while some distance apart its fellow, *C. Marshalli*, is conspicuous by its considerable habit and massive heads of bright orange flowers. Like the dwarf Phloxes, they should be propagated by cuttings as early as possible after flowering, and it is well to keep a spare plant or two in a frame in case a winter of unusual dampness and cold should destroy the larger plants.

While the white *Arabis* which formed such great mounds of silvery bloom so enticing to the bees has become untidy and stands in need of its annual close clipping, there is no lack of white flowers, masses and clumps of *Hutchinsia alpina*, of Candytufts, and of Mossy Saxifrages and many others, supply the snowy feature so delightful at this season in particular. The flowers of the *Hutchinsia* although so small in themselves are so freely produced over so long a period that this plant should be more largely grown, and it is again presented for increased notice.

With such flowers as these and with scarlet *Heucheras*, crimson Thrifts, white Alliums, golden Globe Flowers, pure Poet's Daffodils, blue and pink Squills, the yellow *Morisia hypogæa*, and many other flowers of countless hues and forms, the garden offers its owner treasures of beauty, pouring forth pleasures of highest worth to him who seeks to read her lessons truly.—S. ARNOTT, *Dumfries*.

#### DRACÆNA THALIOIDES FOLIIS VARIEGATIS.

I HAVE read in the report given of the last meeting of the Royal Horticultural Society, and published on page 381 of your estimable journal, that a first-class certificate has been granted for *Dracæna Sanderiana*, exhibited by Messrs. F. Sander & Co., unconditionally, while they have accorded me a similar award conditionally, "subject to its being correctly named," for the same plant exhibited under the name which was given to it in 1888, at the time of its introduction, and by which it has been known since then in the Botanic Gardens of Berlin and of Herrenhausen.

It is certain that the name under which I have shown this plant is correct, since I have exhibited the identical specimen which has figured in the Berlin Botanic Garden since 1888, and have displayed at the same time the very label which the plant bore at Berlin, in a scientific institution of the first rank.

The other part of the plant exhibited by me and that exhibited by Messrs. Sander & Co. have undeniably the same origin; and it is possibly useful and opportune to point out the mistake which has crept into your pages, where it is stated that *Dracæna Sanderiana* has been introduced at Messrs. Sander & Co.'s by Mr. J. Braun. The same plant was introduced at the same time by Mr. Braun into the Botanic Garden at Berlin, and at Mr. Bluth's, a horticulturist at Steglitz. It is at the establishment of the latter that Messrs. Sander & Co. have bought their *Dracæna* which they named last year *D. Sanderiana*.

The priority of the name, *D. thalioides foliis variegatis*, being then well established, the plant exhibited by Messrs. Sander is not correctly

named. It seems to me, therefore, that the certificate awarded to these gentlemen for their plant ought to have borne the same condition as mine, viz., "subject to its being correctly named."

I do not protest against the decision of the Floral Committee, but being quite a new member of the Royal Horticultural Society, I do not

FIG. 71.—DRACÆNA SANDERIANA.

probably yet understand its traditions, and there is a point on which I do not explain myself well. I seek, then, for information from you, and I beg that you will be pleased, by inserting my letter in your next number, to procure for me the explanation which I am desirous of obtaining. It will likewise in all probability interest many of your readers.—L. LINDEN, F.R.H.S., *Brussels*.

[The illustration (fig. 71) represents the plant referred to as exhibited by Messrs. F. Sander & Co. under the name of *Dracæna Sanderiana*.

It would appear from the absence of any condition that the Committee accepted this as the legitimate name, while they did not accept that under which Mr. Linden exhibited the same *Dracæna*; yet according to the above letter it was admitted in the Berlin Botanical Garden in 1888. As the Royal Horticultural Society could not record the expression of a doubt without an intention to investigate the matter with a view to the ratification or removal of such doubt, we may expect to have the final decision of the Society on the whole subject, and we shall be glad to publish it. As our artist happened to sketch one of the St. Albans plants the name under which it was exhibited is given, whereas Mr. Linden is equally entitled to employ the name which he regards as correct, at the head of his communication. It is for the Royal Horticultural Society to say whether Mr. Linden's name is correct or not, since the certificate was granted conditionally. This *Dracæna* is not only distinct from all others but attractive, and we should think easy to grow under suitable conditions. We may add that *Dracæna thalioides*, as first grown in the establishment of Jacob-Makoy, of Liege, about thirty years ago, was found to be a synonym of *D. Aubryana*. This name was given to the plant by M. Brongniart of the Museum of Natural History at Paris, where it was introduced from the Gaboon by M. Aubry-le-Comte.]

### PROPOSAL FOR AN INSTITUTE OF HORTICULTURE, MUSIC, AND THE FINE ARTS.

WILL you kindly favour us with space in your valuable columns to submit a project for the establishment of an Institution of Horticulture? To-day, England is very much behind other great nations in this respect, and although efforts have been made to provide suitable accommodation for our ever-increasing needs, we have no Institute of Horticulture, but exhibitions must be held at odd places, some of them very ill-adapted for such displays.

The financial aspect has been the difficulty. In order to meet this we would suggest that with horticulture should be associated music, the fine arts (all kindred in sentiment), and that the proposed institute should be designed especially to meet the requirements of these societies. There is distinctly a need for a suitable institute for horticulturists, and there is also as great a need for an institute to receive and exhibit the large proportion of paintings which are not hung at the Academy.

Without going into details, we would suggest that a meeting might be held of horticultural gentlemen to confer upon this project, and perhaps meet representatives from the Royal Academy, Royal Albert Hall, Amateur Orchestral Society, Stock Exchange Orchestral Society, or other similar associations, and we believe the outcome of such a conference would be the establishment of an Institute of Horticulture, Music, and the Fine Arts, where, all the year round, pictures and sculpture would be exhibited, concerts of vocal and instrumental music held, and lectures, conversaciones, and exhibitions arranged under the auspices of the Royal Horticultural Society; and all these might, if desirable, proceed at the same time, in the same hall, affording attraction to everyone (for assuredly everyone is interested either in music, pictures, or flowers), and the effect of the three in combination is always harmonious.—W. WOOD & SON, *Wood Green, N.*

[We readily insert this communication, and our readers are free to express their opinions on the proposal of our correspondents.]

### SEASONABLE HINTS ON FLORISTS' FLOWERS.

I VERY much doubt whether the word seasonable is applicable to anything one may write on the subject of the garden during this most extraordinary year, which has been both unseasonable and unreasonable. What can be said of a season when Tulips, which ought to be in flower by the 20th of May, are well nigh over by the 1st of the month; when the Hawthorn has resigned its sweet name "of May," and is in flower at the end of April; when the Laburnum is full of its golden tresses at the same time, and when there is a very great difficulty in imagining where we can possibly be in this year? It is true we hear of a "dismal down-pour" in the North, but I feel sure if it only reached us in the South we should call it anything but dismal. It is all the more felt because we can contrast it with last year, a particularly late season—so late that amongst other things Rose growers got excited over the dates of the shows, and were for making them later; and now! Well, I have heard people talking of putting back their shows a fortnight; there is this advantage in such a climate, that our "hints" must alter—at any rate, as to the time allotted for the various operations.

AURICULAS.—As I have already said, the season has been a very disappointing one to many Auricula growers, and the very early time at which the plants have gone out of flower necessitates a

much earlier removal to their summer quarters. They should be now placed in frames on the north side of a wall or fence. Before removing them from the pits where they have been growing and flowering all through the spring, I always give them a dose of fumigation as it kills all the aphides, which are very injurious to the well-being of the plants. Each plant is afterwards examined, and if any woolly aphis is discovered round the neck of the plants they should be removed with finger and thumb, otherwise they need not, I am quite convinced *now* (although I once thought differently) trouble the grower. When they have been removed, and time can be given to them, the work of repotting may begin, commencing with the smaller plants and offsets first. Some sorts are very prolific in the production of offsets, and some just the reverse, and one may wait for years without getting one, and especially is this the case in the more valuable edged sorts. Some of the selfs readily yield offsets, and even the newer kinds such as Heroine, Black Bess, and Mrs. Potts, will soon be in every grower's hands; while for Magpie, Shirley Hibberd, and others they will have to wait patiently for years.

In potting, whether it be old plants or offsets, the simplest compost is, I think, the best, and the chief ingredient, on which I believe, indeed, the future well-being of the plants depends, is a good sound loam, the top spit of a meadow or down. Did I not hear two of our growers having a confab the other day? "Where can I get some good loam?" was the eager request of the younger grower. "Oh! of course, down near Epsom, the best loam in England," was the reply of the more experienced grower. Well, we cannot all go there, and must only look out for it where we can. There is, however, a mistake sometimes made on this subject. I have heard people expatiate on their heaps of loam laid up for two or three years. I think this is too long. You lose then the fibrous roots of the grasses, which have by this time quite rotted away, and it is amongst them that the roots of the Auricula delight to find their way; moreover, when the fibre is gone the loam is apt to be too heavy, so I think that a heap laid up for about a twelvemonth is in the best condition. If to two-thirds of this and one-third of decayed cow manure, one-sixth of leaf mould, and a little sharp sand be added, it is a compost good enough for anything. I well remember that old George Lightbody used to say that some plants required more loam and some more leaf mould, and he used to have the different ingredients of his compost laid separately on his potting bench and act accordingly; but few, I imagine, will be inclined to take this trouble.

I am inclined to think that it is better to under-pot than to over-pot the plants. I used at one time to think it better to use large pots, but one is never too old to learn, and I remember in my early days that the fine collection of John Dickson of Acre Lane, Brixton, than which I have never seen a healthier, was grown in small pots. Another point to remember is to pot firmly. This is more especially needful where there is a good deal of fibre in the soil, for as that gradually decays the soil somewhat shrinks, and if the potting is loose it makes gaps in the surface which are not good for the plants. When they are potted they had better be kept close in the frames for a few days and shaded, first giving them a good supply of water. They will of course soon lose their outer leaves, but the fresh heart will soon develop itself, giving them promise of the future year.

CARNATIONS AND PICOTEES.—The influence of the season is shown amongst these plants as in others. I winter my small collection, or rather selection, in pots, and plant them out in March or April. They have not had a drop of rain since they were planted out, and the great amount of sunlight and warmth has caused them to spindle for bloom fully a month before their time. We had had little of the cold cutting winds we too often experience at this time of the year, and this has to some extent compensated for the drought. I have noticed of late that when the talk is about Carnations, it is the border varieties that people have most in mind, and there seems to be an evident decrease in the interest felt in the more refined varieties of the florists; but whether it be show or border varieties, all are much too early on the move. They are now spindling up for bloom, and will require staking at a much earlier period than usual; mine have been done some time. I find that where the plants have been attended to in the matter of watering that the grass is growing well, and that one may hope to have some produce by-and-by.

PANSIES.—This is a very trying time for these plants in the south of England, which is never very favourable for them; and where they have been planted in beds I should think very large gaps will be found. My few are in pots, where they can be more readily supplied with water and shaded. This is all the attention they will require now, except that the pots must be kept clear of weeds, and any long shoots tied to short sticks. The forthcoming Exhibition at the Drill Hall will perhaps give an impetus to their culture; but here, as in the Carnation, it is not the old how

varieties which attract the most attention, but the Fancies which violate all the old rules of the florist, and for their variety of colour are much appreciated.

**GLADIOLI.**—The only thing that can be done with these at present, unless it be what I am very much disposed to do on account of the drought, viz., mulch the beds with short manure and then water them. If, as I have been told by some wise man, "the cause of my disasters last year was the excessive moisture" I ought to have some hope that the very opposite extreme would be favourable. I, however, think that some moisture is desirable, and so shall mulch; the plants seem to have come up well. I believe it is much better to give help early if it is to be given and then to wait till the growth is made.

**RANUNCULUSES.**—It has been an especially trying time for these roots, which, like most of the tribe, are moisture-loving plants. It is a good plan to give them a top-dressing of about an inch of leaf mould, and then to water between the rows. The beds should be kept clear of weeds. I find that, notwithstanding the excessive drought, the plants look well, but I am afraid that they will be much too early.

**ROSES.**—Notwithstanding the hopes entertained by "W. R. Raillem" (page 310), I do not find, at least in my own case, that the maggot has left us alone. It seems to be about as abundant as usual, and the same measures must be adopted for getting rid of them—hand-picking; there is nothing that can do it half so effectually. I do not know what will be the upshot of the present state of things, but so far as present appearances go the Rose shows ought to be in the end of May and beginning of June; but there is a good period yet to be got over, and we do not know what effect May will have. If we get that cold wave we have had of late years about the 20th it cannot fail to be disastrous. Let us hope it will not visit us this year.—D., Deal.

### SPRING GARDENING AT BELVOIR.

[By Mr. W. INGRAM. Read at meeting of the Horticultural Club, May 9th.]

IN introducing the subject of spring gardening I may venture to speak of the extremely satisfactory results that attend the system when fairly carried out. Flowers seem so welcome in early spring, and there are associations and sentiments in some of them that appeal to all natures, whether lovers of flowers or not. The Primrose, Forget-me-not, and Daffodil are replete with memories of early days. I have repeatedly enlisted the attention of people confessedly indifferent to floriculture by a walk through the spring gardens; the very simplicity of the materials employed seemed a special merit, and excited surprise and admiration. The uncertainty of our variable climate will not allow us to rely with assurance on securing a great display of flowers so early in the year as February, but there are happily plants ready to respond to the first warm gleams of sunshine, and it is seldom that April passes without awakening from their winter's rest the Violet, Aconite, Snowdrop, and Hellebore.

The period of spring might be floriculturally divided into three parts according to the time of blossoming of the vernal flowers—February and part of March, mid-March and early April, the rest of that month and May. The second period is rich in interesting plants chiefly bulbous, that supremely beautiful plant *Chionodoxa Lucilæ* being conspicuous. With it appears *Anemone blanda* and *cœrulea*, *Scilla sibirica* var. *bifolia*, *Iris reticulata*, and *Corydalis cava*. The five first named grown in masses caused a lady to exclaim, "Oh, Mr. Ingram, you have brought the sky down to the earth!" The third period is rich in many handsome plants and the more showy bulbs; but to these I shall advert in due course. The preparation of the various plants that belong to this system of gardening is a matter of very considerable importance. It is seldom that the commoner plants specially adapted to the purpose can be obtained from nurseries; in every way it is better to prepare them as near the home garden as possible, and there are several reasons why this course should be pursued.

We are all more or less aware of the influence exercised by soil in promoting health and vigour in plant life, and the opportunity of employing the various kinds known to be most suitable is one to be especially valued. It happens that soil of the most opposite character is called for. *Erica carnea* is one of the most charming plants for early spring, and peat or a light silicious soil is required for its successful culture. Another plant, the Wallflower, which I grow largely, prefers a soil which would be death to Heaths; it revels in a light calcareous soil. I find it advisable to prepare beds by dressing with lime scraps or old mortar; and when the seedling plants are pricked out and established we check a too vigorous growth by lifting each plant with a fork, so as to break the deeply penetrating roots, thus causing a compact

mass of fibres to be produced. Wallflowers will grow in any soil, but plants so treated are less liable to injury from frost. Many hundreds were treated in this way last year, and I do not think I lost half a dozen from weather.

I may relate an instance of the success attending an experiment in preparing suitable compost for the Primrose, a plant singularly impatient of drought, and large numbers perished annually even on our heavy unprepared land. From this cause I was able to provide beds of materials composed of grass sweepings from lawns, leaves, and a small quantity of decayed manure, which I carted on to some rough outlying land to a depth of between 2 or 3 feet, enough, indeed, to smother all weeds beneath. When turned over several times rolled and settled down on this I placed a layer of soil. I had then a bed retentive of moisture, rich in decomposed vegetable matter, which annually improved, carrying successive crops of Primroses and other spring plants.

One of the most useful and reliable plants for spring decoration is the *Aubrietia*. It is a plant that readily adapts itself to very varying circumstances. It thrives in the rich soil of the kitchen garden, it does equally well in the herbaceous border, and spreads and blooms abundantly on rockwork, deriving support from the poorest soil. I raise thousands of seedlings annually from the typical garden kind, *Aubrietia græca*, which affords many shades of lilac, some approaching purple. I once obtained from seed a light pink variety, but it remained for that indefatigable and successful horticulturist, Herr Max Leichtlin, to secure a magnificent variety, justly named after him. Its rich crimson flowers in masses give an effect unsurpassed by any plant I possess. Rosy plush is another contribution from Baden. I have also a white kind from Mount Athos, but it is not floriculturally valuable.

I grow an allied plant, *Arabis albida*, largely. It is useful in combination with other plants; its pure white flowers form a pleasing contrast with *Scilla sibirica*, and later in the year it forms a good base for scarlet Tulips. Another plant extensively employed at Belvoir is *Saxifraga ligulata*. It has the merit of blooming early. It is sometimes cut down by frost, but this may be averted by Fir boughs. Even when the bloom is over its broad leaves cover the ground and provide foliage or a substitute for Hyacinths freely planted amongst it. *Saxifraga Stracheyi* is one of the handsomest of the tribe, but is so often injured by frost that a cautionary recommendation must accompany mention of it.

I need hardly say that I grow large numbers of Violets. Having sunny and sheltered banks this universal favourite may be, and is, gathered throughout the winter. One advantage I possess is ample supplies of leaf soil; useful when properly prepared for many plants besides Violets. It is essential that Violets be divided and replanted every year. I obtain some fine effects from the use of two kinds of *Doronicum*, *excelsum* and *austriacum*. This season they have been exceptionally fine. A bold, free blooming, and hardy white *Cardamine*, known as *rotundifolia*, deserves more general cultivation. It has been objected to as having a coarse common appearance, but it is my doctrine that all hardy early blooming plants must be received with thankfulness. It blooms throughout April. One of the most effective and generally useful plants is the yellow *Polyanthus*; it blooms freely, and produces a compact mass of the purest yellow. I raise many thousands from seed every year. In favourable years they can be utilised the first year, but I depend generally on two-year-old plants. A pale yellow variety is effective associated with *Aubrietia*. There are few plants more admired and cherished than Primroses, both double and single. The former, alas! resent removal in the spring, and I cannot boast of a good stock. The single crimson and white form some of our best beds.

I will try to classify the plants I chiefly employ according to their time of blooming. I have one large detached bed on a sunny slope on which I have planted masses of the flowers that may appear in February, and are pretty sure to do so before the middle of March. The first of these to flower is *Crocus Imperati*; *Aconites* and *Snowdrops* soon follow; then *Anemone blanda* and *Chionodoxa Lucilæ*, followed by *Scilla sibirica* and *bifolia*. The beautiful *Iris reticulata* succeeds, then *Puschkinia scilloides* presents its bluish-white blossoms. The common kinds of *Crocus* form a fringe to this large bed, and the earliest blooming Primrose serve as a bordering. In warm seasons I can rely on *Narcissus præcox superbum* and *N. Stella*, and also the dwarf *Narcissus minor*. Come frost or snow, wind or wet, I may always depend on the hardy and handsome *Saxifraga oppositifolia*. I can speak strongly of the interest and beauty of a bed thus occupied and arranged.

The next division of the early season is mid-March and early April. *Erica carnea*, *Saxifraga ligulata*, the early *Narcissi*, *Arabis albida*

Aubrietia græca, Polyanthus, Primrose, Hyacinths, Tulips, Cardamine rotundifolia, the later Hellebores and Myosotis dissitiflora.

The third division will include the foregoing, with the very important addition of Aubrietia Leichtlini, many Narcissi, Hyacinths and Tulips, Alpine Auriculas, Daisies, Wallflowers, both double, dark, and yellow, also Doronicum excelsum and austriacum, Myosotis dissitiflora, and M. alpestris Victoria.

Beds which we make up with various plants, although not giving a great effect of colour, are, nevertheless, interesting from the variety of plants they contain. They are useful in receiving plants when the stock is insufficient for masses, or when their duration of bloom is short. In these we have Hepaticas, Anemone nemorosa plena and A. Robinsoniana, Tiarella cordifolia, Saxifraga oppositifolia, Pulmonaria, Cardamine, Narcissi, Epimedium maceranthum, double Primroses, Saxifraga muscoides atro-purpurea, Corydalis nobilis, C. cava, Ranunculus montanus, this year a veritable gem; Adonis vernalis, Dog's-tooth Violet, and the Alpine Daisy.

A description of some of the bedding arrangements may be of interest. I will just slightly mention some that have been much admired. In one part of the castle garden there are six beds 5 yards across holding about 100 plants.

1, Aubrietia Leichtlini, edged with Alpine Daisy, and dotted with about fifty yellow Tulips. This is a very striking and effective bed, and most enduring.

2, Arabis and Scilla sibirica, edged with dark crimson Daisy, and dotted with scarlet Tulips.

3, Yellow Polyanthus, edged with dark red Daisy, pricked out with dark red Tulips.

4, Aubrietia græca, edged with pink Daisy, and dotted with Couleur Ponceau Tulips.

5, Heath, edged with Heuchera Richardsoni, and dotted with yellow Tulips.

6, Crimson Primrose, white Tulips, pink Daisies.

There is another set of beds which I call from their make up bouquet beds. These have a centre of Erica carnea, edged with variegated Arabis and succeeded in bands by yellow Polyanthus, Aubrietia and yellow Primrose. Red, white, and blue Hyacinths brighten the central part of the bed.

In this garden there are raised beds, some filled with the two Doronicums, and others with dark Wallflowers and yellow Daffodils. A very large bed in the centre is filled with yellow Wallflowers, banded by Myosotis and followed by Aubrietia Leichtlini and Daisies.

I have not space to continue the description of beds, having left out our best garden, called after the Duchess.

#### HAZEL BUD AND PEAR LEAF MITES.

I HOPE Mr. J. Hiam (page 358) has procured specimens of Hazel bud's infested with mites, and has subjected them to microscopic examination. It depends, however, upon the buds taken for finding the condition I found them in on April 7th, which is shown in the *Journal of Horticulture*, April 20th (page 321). On weakly growths, feeble or lean bushes, and aged trees, ninety-nine per cent. of the buds in the condition shown on April 20th (page 321), remained in the same state up to May 6th as they were found on April 7th, that is, they were utterly destroyed, and the growths, bushes, or trees presented no evidence of continued existence beyond a straggling growth here and there.

On May 6th buds on strong wood and vigorous bushes had pushed a little growth, and instead of the attacked buds being entirely destroyed they were making efforts at elongation, forming what are called witch knots. This latter term is very misleading, for the witch knots caused by mites only apply to the bud growths of the Birch, Currant, Hazel, and Yew, and instead of remaining undeveloped, as in the cases just recited, enlarge to a conspicuous size, or grow into stunted branches, the cone-like protuberances or bunches attaining the size of a hen's egg, and, if repeated, the growth of the stunted branches may become as large as a cricket ball. These witch knots must not be confounded with the curious clusters of twigs that frequently occur on Birch, Bullace, Hornbeam, and occasionally on Fir trees, which at a distance resemble a bird's nest formed of twigs, for these are the work of minute fungi belonging to the Ascomycetes group.

Examining the attacked Hazel buds not killed by the mites on May 6th, I found the what should have been shoot leaves and buds had produced a luxuriant crop of outgrowths, an enormous quantity of hairs, and on these the mites were browsing. They were generally of the form shown in c, fig. 61, *Journal of Horticulture*, April 20th, 1893 (page 321), but of different sizes. There were no eggs nor empty sacs, and the whole nest was as clean as "a new pin." But I was for a long time disappointed, for there was something in the life history of mites I wanted to get at, the cycle being broken for want of a certain "missing link." The four-legged mites do not pair but increase by "budding,"

and in the spring they become as retiring as a fowl moulting. What the creature was like after the metamorphosis was the grand secret. Whilst I was examining, putting fresh slices on the slide one after another without getting at anything farther than has already been described, almost blind with searching, and leaving the last slice of infested bud on the slide, I took a rest to recover clear vision preparatory to putting the things away clean and tidy, an imperative necessity in microscopic operations. Notwithstanding, I was not by any means satisfied; I knew the thing was there, only it would not come into view, therefore I took a last "fond look," and was rewarded, for a creature appeared as large as a woodlouse is to the naked eye under the same magnifying power as the four-legged mite, shown on page 321 at c, was subjected to, and it had eight legs. This is what I was in search of, a fertilised female capable of traversing the naturally hairy young growths of the Hazel, piercing the young buds, and depositing its eggs in them. The cycle is now complete. I cannot agree with Mr. Gibbon and Mr. Hiam that bud gall mites are all one species. The late Mr. Andrew Murray is very clear upon this point, and does not make one figure of a bud gall mite do service for five species. There is a difference between the Birch and Currant buds gall mites. True it is slight, and only an expert would notice what the difference is, but it is enough to show that the representation in books in many cases are mere copies, often of continental specimens, which are larger, if not better than ours, they are made to do duty for.

As regards the Pear leaf gall mite, I shall be pleased to examine any specimen Mr. Hiam may send, through the recognised channel. I may say, however, that I have worked out the life history of the Pear leaf mite, and in some points connected it with a certain form of canker, but I am not certain when and how the mites attack the wood and produce the cankerous affection. If Mr. Hiam will kindly send to the Editor specimen of the current year's growth with galls on the leaves early in June, similar specimen with two year old early in August, and similar specimen immediately before the leaves fall in autumn, I will see what I can make of them and report in the *Journal of Horticulture*. I have the specimen of the fertilised female Mr. Hiam submitted to the Editor in the spring of this year. Fresh specimen of these might be submitted for inspection between the fall of the leaves and the appearance of new growth.—G. ABBEY.

#### FRUIT PROSPECTS—INSECTS.

STRAWBERRIES look very well, but the drought will probably shorten the duration of the crop. Here we have had no rain sufficient to lay the dust since March 1st. Gooseberries a good crop. Black Currants very short. Red Currants good, though have fallen much in consequence of the dry weather. Plums and Cherries good at present, but they keep getting fewer. Apples and Pears very good. I do not think the cold winds while the fruit was in bloom have been injurious, for the old saying is, "A cold blow suits Cherry bloom," and according to my observation this is correct. The blossom seems less injured by frost when the weather is dry and cold.

With the cold winds and the dry weather insect pests are very numerous, particularly green fly and red spider. For the latter on Gooseberries we have till recently had no cure, as the usual washes do not kill it, and they walk about under hellebore powder with perfect indifference. As when once established it returns usually every year during hot, dry weather, bushes are much injured by it, and in a few years are worthless. Some growers here are having to grub a number of bushes through this. We have now found that the "Curative" wash applied about 1 in 20 kills them. For Gooseberry caterpillar we find nothing better than hellebore powder, which kills very quickly, but of course it must not be applied near gathering time. We have had an unusual visitation this year, and had to go over all our bushes, and as soon as we had been round another batch had arrived, and we had to go over the bushes again. Still insects must on no account be allowed to remain unchecked, or good-bye to fine fruit and heavy crops.—WALTER KRUSE, *Leeds, Kent*.

FRUIT prospects are fairly promising hereabouts, and if frosts be done with I think we shall have an all-round satisfactory crop. The long succession of bright days and frosty nights—except on the night of the 11th ult., when the bulk of half-opened blooms were killed—does not appear to have left us any other evil legacy, and would but the long-deferred rain in kindness remember us the year 1893 bids fair to be remunerative. Fortunately on that sharp night some two-thirds of the bloom took no harm, and as the weather since has been very satisfactory for pollen distribution, a sufficient "set" will still be secured. Our Vines and Peaches too I may say are highly satisfactory, and the thinning some three weeks earlier than usual will be finished this week. With the breezy bright weather Tomatoes are also setting well, and so far are, I think, healthier than usual.—JOSEPH WITHERSPOON, *Red Rose Vineries, Chester-le-Street, Co. Durham*.

THE unfortunately persistent dry weather, besides its other prejudicial gardening effects, has prematurely invited the Gooseberry caterpillar, and in many instances, as in my own garden, induced its appearance where it was never seen before. I thought of using dry flowers of sulphur, and with the best effects. I say dry, for if in the least damp it will be useless. Scatter it with a spraying canister wherever the caterpillars appear or may reasonably be expected, and the least touch immediately kills them. Now is the time, before the eggs are laid, and

before your Gooseberry bushes are defoliated. The loss of the foliage means worthless fruit and a crop of caterpillars next year.—W. J. MURPHY, *Clonmel*.

I AM pleased to record a break in the drought. On Monday, 15th inst., we had a thunder shower of half an hour's duration, in which 0.10 inch fell. We have a very good set of Apples and Pears, Cherries and Plums. Blight of all kinds is very prevalent. We have already sprayed our trees three times, once when in bloom with clean water, next with softsoap and petroleum, and lastly with carbolic soap and quassia.—ROBERT MAHER, *Yattendon Court Gardens, Newbury*.

### NEW PANSIES.

I HAVE recently had opportunities of inspecting the large collection of Pansies grown by Mr. W. Sydenham at Tamworth, on soil which suits them admirably—fresh loam on a newly broken up piece of pasture land, and the plants were strong and producing fine blooms. Some of these were seedlings raised by Mr. J. D. Stuart of Belfast, and other raisers, and several have not yet been sent out, but will be in the autumn should they maintain the promise at present held out of taking foremost rank. At the forthcoming great Midland meeting of the Midland Pansy Society at Tamworth a further opportunity will be offered of seeing them and many other new kinds, as raisers from Scotland, the North of Ireland, and other places will be present.

The following notes taken at the end of April of new sorts at Tamworth may be of interest to many Pansy growers—viz., Emmie Stuart, pale yellow with carmine markings, large very solid blotch, and of fine form; Mrs. Walter Fisher, white with rosy purple markings, solid blotch, and excellent form; Harry Thring, a Miss French style of flower, very rich in colour, and of the finest form. Mrs. Chadwick and Andrew Allison are both promising. Dorothy Gladwin is an improved My Lady. Tamworth Yellow has been very good, rich in colour, with a large dark solid blotch. Sunlight is a pretty flower, and Mrs. Willie has a fine blotch and is a good all-round flower. Emily Renk, Thomas Garrett, and Annie Garrett are all very pleasing useful exhibition flowers. Andrew Frater is a Scotch variety, a great acquisition, the upper petals marked with rosy carmine, with large solid blotch, and medium pale yellow margin. Emmeline is a fine flower, top petals rich crimson tinted mulberry shade, with grand solid large blotch, with gold and rosy crimson markings. The Rev. J. Gressly and Mrs. B. Dick are very promising. William Adam, rich gold ground with crimson maroon marking, and large solid blotch; Mrs. Thompson, and Mrs. Train are all acquisitions. Forbes's Miss Jessie Campbell is rich in colour, and his Mrs. Street is a good flower with large solid blotch. William Watson is truly a grand flower in every way, a light ground flower with a superb blotch. William Scott is an improved Mrs. Scott, white self with large dark solid blotch. Mrs. William Sydenham is very rich shaded deep crimson violet in colour, with dark blotch and white markings, and very distinct. May Spence and Betsy Kelly are also very pretty.

Of those already out, the following may be regarded as fair exhibition varieties, and very moderate in price—viz., Agnes Mormon, a fine light flower; William Caldwell, Mrs. Lister, Donald Morrison, Mrs. Hugh Weir, John Lamont, Lord Buta, Louis Wierter, Thomas Hastie, Mrs. Grossart, Mrs. Henderson, Julia Goodfellow, Lieut. McIsaac, Miss Helen Hunter, Mrs. C. L. Carnegie, John Coutts, Miss Hudson, Mrs. Patterson, Mrs. Fleming, Tom Travis, Weir's Hugh, Mr. Maxwell, Mrs. Taylor, Mrs. A. Irvine (a grand white self, with an almost black large blotch), Maggie Pinder, May Hynd, Mrs. W. Dean, Agnes Mabel, David Rennie, Dusty, Royal Arthur (style of Niel McKay, good blotch), Kayii, William Ross, William Evitts, Mrs. Hastie, Mrs. Atkinson, Kate McArthur, Maggie A. Scott, Joe, Clandeboys, Robert Craw, Archie Buchanan, Niel McKay. From these amateurs may safely select for additions to collections, as well as for forming one.—WILLIAM DEAN.

### THE SCOUNDREL SPARROW—THINNING.

IN answer to Mr. Arnott, I cannot see the connection between want of water and sparrows destroying Apple buds, for, as far as I can judge, they do not eat them, but simply pluck them off and let them fall. As a matter of fact a stream of open water runs through my grounds, and some of the buds I saw plucked off were actually falling into the water. We have a fine set of such Apple blossoms as were left, as well as of Pears, Plums, and wall fruit, with very little blister on the latter. Most of the crops will have to be thinned; and really, if the sparrows had thinned the blossoms instead of absolutely stripping some trees and leaving others, good instead of harm would have been done this year.

I remember that some good person or other, taking note of three successive operations on my Rose beds—thinning shoots, destroying grubs, and thinning buds—pointed out to me that if I left Nature alone the grubs would have done all this thinning for me. I requested him or her (the latter I fancy) to go and inspect certain Rose beds in another garden which had been left to the operations of Nature, and remarked that gardeners liked to do the thinning themselves. It was Mr. G. Paul, I think, who told me he once employed some women to thin the buds on some Rose plants for exhibition purposes. "Look here," said he, pulling off all the buds round the central one of a truss, "I want you to take off all these." They set to work with a will and left not a bud of any sort on the row!

Mr. Arnott says he pleads guilty to harbouring the sparrow, which at present has not molested him. I prophesy that for him, too, "a time will come." It is only when the sparrow *has* been harboured for a long time, and has therefore increased beyond reason, that he becomes a plague. A neighbour of mine has done an illegal act. He put down a little poison for the sparrows, and the next day picked up on his own premises—doubtless many more died further away—450! I am thoroughly opposed to the use of poison in any way or for anything if it can possibly be avoided, and only mention it to show that when sparrows have increased to such an extent they must be treated as vermin.—W. R. RAILLEM.

RELATIVE to the alleged depredations of "our birds," what would we think of a person censuring, because it might be his coat had been torn, those who had saved his life. Whilst poking into the bloom truss to secure the snugly ensconced caterpillar, the sparrow has been seen to drop a stray petal, and he is not only to be censured but he is to be utterly exterminated. How strange it is that the saying that "the murderer secures the nearest cut to heaven" is not only justified, but it is equally true that those who wish to be evilly spoken of have only to practise replacing evil with good to succeed. Since reading the recent bird paragraphs I have been thinking you, or any of your representatives, might do good service by visiting and reporting on a few places where the two extremes are practised, and let the results declare which are the ways of wisdom. I enclose you a slip on which you will find my views more fully, and with or against, I would be glad if you would give us a few lines of criticism. Red spider I see has made an attack on the Gooseberries, and so far I regret that we have not had time to attend to it.

Parent birds seek for their brood the best procurable food, but they will not fly half a mile for it if they can get it near at hand, and as a dog will eat grass for its good, so will birds devour green food if within their reach. For the protection of my one and a half acre of trees and fruit bushes, situated some 600 yards from the town, I have within the walls about twenty-five pairs of sparrows, and my Gooseberry bushes are never touched. As for sparrows eating the blooms I have as yet only heard of the performance. These are stern unattackable facts. During the first year after the serious frost previously referred to, I dusted my bushes with hellebore powder. Amid the shoals of dead caterpillars that lay under every bush, I discovered several dead sparrows which had evidently been killed by eating the poisoned pests, and so I had it proved conclusively that they did eat the Gooseberry caterpillar. I provide nesting places, and thus have birds so near my caterpillars and so far away from house morsels, that they eat the pest greedily; but fruit crops being thereby secured, we must next draw on our ingenuity to prevent the birds taking more than their fair tithe, and this can be done with nets.—J. WITHERSPOON.

[Our criticism will be brief. In some districts where sparrows abound it is a question of nets or no fruit if the birds are not otherwise dealt with. We have seen Gooseberry and Currant bushes ruined through being denuded of buds by sparrows when there were no caterpillars; at the same time we are always pleased to hear of cases where sparrows are so few, orderly, or well managed that they do more good than harm in gardens.]

### ANTIPODEAN APPLES—PACKING SCIONS.

YOUR correspondent, Mr. W. J. Palmer, The Nurseries, Carleton Gore Road, Auckland, New Zealand, in his remarks on Antipodean Apples (page 371) kindly offers to send to me a few young trees of Northern Spy Apple on their own roots. I should be pleased to receive them, and if at the same time Mr. Palmer is inclined to send any scions of new Antipodean varieties I should feel a pleasure in delivering them to Mr. Barron at the R.H.S. Gardens, Chiswick.—ROBERT MAHER, *The Gardens, Yattendon Court, Newbury, Berks*.

[We have from time to time received scions of fruit trees packed in various ways, for keeping them fresh during long journeys. Cherry scions from Australia, packed in slightly damp moss, then tightly enclosed in oiled silk, arrived in the best condition. They were buried in damp soil for a few days, as there was a slight suspicion of shrivelling. This freshened them, and all the varieties grew well when attached to the stocks. Oiled silk properly applied prevents the escape of moisture from the scions much better than any charcoal packing can do.]

### LONDON PURPLE AND GOOSEBERRY CATERPILLARS.

FOR some time past I have been troubled with the caterpillar upon my Gooseberry bushes, which threatened to destroy both fruit and leaves, and after trying various remedies to effect a cure I was compelled to resort to London purple—a preparation I have hitherto been very prejudiced against. Whenever I have used it before, it has burned the foliage of whatever I have tried it upon. Owing to this evil I had left off using it; but reading the other day the method of mixing given by a Frenchman it led me to make a further trial, which turned out a success, one application clearing the bushes of all caterpillars. I have accordingly dressed all my bushes, and in the course of forty-eight hours had the satisfaction of not finding a single caterpillar alive. Those who fear its use owing to the arsenic remaining on the fruit, have only to wash the Gooseberries as they gather them, or give the bushes a good syringing

with clear water in the event of us getting no rain. The strength and mode of mixing are as follows:—

Boil for ten minutes 4 lbs. of common sugar in 1 quart of water, stirring so as not to allow the sugar to burn; add 2 tablespoonfuls of this syrup to 2 teaspoonfuls of London purple, make into a paste, allow to stand for half an hour, add to 3 gallons of water well stir; slightly dew the bushes with a sprayer, and in the course of a few hours they will be freed from the pest.—E. WALLIS, *The Gardens, Hamels Park, Buntingford, Herts.*

**EVENTS OF THE WEEK.**—A special show of Orchids, cut flowers, and fruit will open to-day (Thursday) at the Gardening and Forestry Exhibition, Earl's Court, and continues the following day. On Friday, the 19th, an exhibition of Orchids and other plants will be opened at the Botanical Gardens, Manchester, this continuing until the following Thursday, on which day the Temple Show of the Royal Horticultural Society opens.

— **THE WEATHER IN LONDON.**—After a prolonged spell of drought (73 days) a welcome change has taken place. On Monday a slight shower fell in and around the metropolis, but not sufficient to do any material good to the crops. On Tuesday, however, several showers occurred, and during the night it rained heavily at times. As we are going to press it is close and cloudy, with every appearance of rain.

— **WEATHER IN THE NORTH.**—Summer weather has prevailed throughout the past week, with an occasional chilliness in the evening from the wind veering into the N.E. There has been a shower during the past night. This morning (16th) is dull, and the barometer is falling slightly. The much-needed rain seems to be coming.—B. D., *Perthshire.*

— **PRESENTATION PORTRAIT OF MR. HARRY J. VEITCH.**—It will be remembered that the gardeners of the United Kingdom presented to Mr. and Mrs. Harry J. Veitch a silver dessert service, also a case of silver dessert and fish knives and forks on the occasion of the twenty-fifth anniversary of their marriage on the 6th of August last. It may also be remembered that it was decided to present Mrs. Veitch with an oil painting of her husband as soon as it could be completed. Mr. George Clausen, an artist of public repute, was entrusted with the work. It has been a long time in progress, but will be completed this week. On Monday next the portrait will be on view in the nurseries at Chelsea, and continue open to inspection for some little time, including the Temple Show week, when it may be expected that many gardeners will visit the metropolis. Those who call at Chelsea, and all are welcome, will find a life-like delineation of Mr. Veitch, uniform with and worthy of a place among portraits of his father, grandfather, and great-grandfather which hang in the room.

— **THE TEMPLE FLOWER SHOW.**—We are informed that all arrangements have been made for the Show to be held on Thursday and Friday, May 25th and 26th. Intending exhibitors are requested to give notice of their exhibits immediately to the Society's Superintendent, Chiswick Gardens, who will arrange for the requisite space being allotted. Exhibitors' names, if received in time, will appear in the special catalogue of the Show. The Council have arranged that gardeners (*i.e.*, *bonâ fide* employés in a private garden, nursery, market garden, or seed establishment) may obtain 2s. 6d. tickets for 1s., which will admit them to the Exhibition at ten o'clock on Friday morning, May 26th. These tickets can only be obtained previous to May 24th from the Society's Office, 117, Victoria Street, S.W., and a stamped and directed envelope must be sent with postal orders in every case.

— **MORISIA HYPOGÆA.**—One of the prettiest plants now in bloom on the rockwork at Kew is this Crucifer. The flowers are yellow, set thickly amidst the leafage, the which though smaller bears resemblance to that of the American Cress. The plants are mere tufts, some 2 inches in height, and really a beautiful little thing for rock corners. It is a native of Sardinia, and may be propagated by seed or by cuttings or by division.—D.

— **THE ROYAL GARDENERS' ORPHAN FUND.**—At the monthly meeting of the Committee which took place at the Horticultural Club recently, the Hon. Secretary announced that the dinner receipts amounted to £492 6s. 6d., in addition to the promise of £100 from the directors of the Gardening and Forestry Exhibition at Earl's Court.

— **BOTANICAL APPOINTMENT.**—We understand that Professor Mobius, of Heidelberg, has been selected to succeed the late Dr. Jannicke as second librarian and Professor of Botany at the Senckenberg Institute, Frankfurt-on-the-Maine.

— **GARDENING APPOINTMENTS.**—Mr. Hy. Watt, for the last twelve years head gardener to G. L. Watson, Esq., Rockingham Castle, Northants, has succeeded Mr. Gilbert as head gardener to the Right Honourable the Earl of Ancaster, Normanton Park, Stamford.

— **THE "KEW BULLETIN"** for February and March contains, as usual, much information. The part opens with an instructive article on the Palm Weevil in British Honduras, accompanied with two plates. There are also "decade 5" of new Orchids, and a number of miscellaneous notes from which we extract the following three paragraphs.

— **KEW APPOINTMENTS.**—Mr. Gustav Hermann Krumbiegel, a sub-foreman in the Royal Gardens, has been appointed Superintendent of the State Gardens under the Government of His Highness the Maharaja Gaekwar of Baroda, in the Bombay Presidency. Mr. Frederick Enos Willey, in the employ of the Royal Gardens, has been appointed Acting Curator of the Botanical Station at Aburi, under the Government of the Gold Coast, during the absence on leave of Mr. W. Crowther.

— **MELHANIA ERYTHROXYLON (AIT).**—This is the Redwood of St. Helena, an endemic tree 20 feet high, bearing large tubular flowers, white when first expanding, changing in a day or two to pink, and finally to red. It is now almost extinct in the island. In 1883 Mr. Morris, the Assistant Director of Kew, when on a visit to St. Helena, brought home seeds of this plant, which were widely distributed. Plants were successfully grown at Jamaica and put out at the Hill Garden attached to the Government Cinchona Plantations. It is doubtful, however, whether any of them have since survived, as the tree is, evidently, difficult to grow under cultivation to a mature state. One of the last of the plants raised from the same seed at Kew was killed during the winter of 1891. It would be interesting to learn whether the tree has been successfully grown elsewhere outside St. Helena. In order to make further trial of its application for a good supply of seed was made a short time ago to Mr. W. Grey Wilson, C.M.G., Governor of St. Helena. This was obligingly sent in November last, and a portion was at once distributed to the following botanical gardens—viz., Berlin, Edinburgh, Glasnevin, Paris, Antigua (Leeward Islands), Hakgala (Ceylon), Jamaica, Natal, Port Elizabeth, Sydney, Trinidad, and to T. Hanbury, Esq., at Mentone. The seeds sown at Kew germinated in a few days, and there are now numerous healthy young plants.

— **CALIFORNIAN PLANTS.**—Kew is indebted to Professor E. L. Greene of the University of California for a parcel of about 300 dried plants from Western Northern America, mostly from California, and largely consisting of types of novelties described by him from time to time. The specimens are excellent, and form a valuable addition to the Herbarium.

— **TULIP PICOTEE.**—This charming Tulip was referred to on page 374, last week. The flowers are largely grown for sale in bunches. Mr. Ware, jun., of Bath, son of the well-known Mr. Thos. Ware of Tottenham, grows thousands of blooms for market, and other beautiful varieties, which are comparatively little known. Golden Eagle, rich deep yellow, also referred to last week, will become very popular. The old Tulipa Gesneriana, the parent of the modern late-flowering florists' Tulip, is amongst our brightest and handsomest early flowering bulbous plants, and as it is so cheap no garden should be without it.—W. D.

— **SYRINGA JOSIKÆA.**—Lovers of hardy flowering shrubs should make a note of this pretty Lilac. It seems to stand the hot, dry weather better than the common kinds. I saw a dwarf bush of this flowering at the Durdans, Epsom, last week. It appears to grow freely in light, dry soil. The flowers are of a deep colour, and I should think stand longer than the common one owing to their firm texture. It is by no means a new variety, for I see it was introduced from Germany as far back as 1833. Still it is by no means common, and should not be lost sight of among the host of newer varieties.—J. SMITH, *Mentmore Bucks.*

— **HORTICULTURAL CLUB.**—We understand that it has been decided to have a special dinner of the Club on Thursday, the 25th inst., the first day of the Temple Show of the Royal Horticultural Society. The experiment was tried last year, and it was so great a success that the Committee have decided to hold one this year.

— **BEGONIA ARTHUR MALLET.**—This is a great favourite in the market, because of the rich red colour of its leafage. It belongs to the shrubby section, and may be propagated by cuttings. Specially for vase or sideboard decoration is this Begonia suitable, for the foliage is singularly effective.—A.

— **LINUM PERENNE.**—As growing in the herbaceous garden at Kew this is a rarely seen charming hardy perennial plant of the usual Linum character, from 15 to 18 inches in height, and carrying profusely lavender blue cup-shaped flowers. This is a hardy plant that merits much wider cultivation.—D.

— **THE WEATHER IN WEST YORKSHIRE.**—Rain fell in this district (Bingley) on the 16th inst. after a long period of dry weather. Terraces and slopes present in some places a parched and brown appearance, similar to the summer of 1887. Apples and Pears in orchards have set remarkably well, although the long-continued spell of drought has caused wall trees to shed a portion of their blooms.—T. H. B.

— **HEAT AND DROUGHT IN HANTS.**—Mr. E. Molyneux informs us that another week has passed without rain, and that the thermometer registered 89° in the shade last Saturday, the minimum night temperature being 50°. On mentioning this to a gentleman who is interested in these matters he observed:—"Perhaps Mr. Molyneux's thermometer is a little hotter than the weather." Has it been tested throughout the whole of the scale?

— **FLORA OF KENT.**—According to *Nature*, Mr. Frederick J. Hanbury and the Rev. E. S. Marshall are engaged in the preparation of a Flora of Kent, which should prove an exceptionally rich county flora, though some districts have as yet been but imperfectly searched. Any assistance will be gladly received by the Rev. E. S. Marshall, Milford Vicarage, Godalming.

— **CANADIAN FLOWERS.**—From the same source we learn that Mr. A. T. Drummond has been investigating the colours of flowers in Ontario and Quebec in relation to the time of flowering, and has contributed to the "Canadian Record of Science" an interesting paper on the subject. He finds that April, May, and even June and July are remarkable for the prevalence of white flowers. July and especially August of yellow, and September and October of purple and blue.

— **BEDDED-OUT DANDELIONS.**—In one of the flower beds at Kew is a number of Dandelions planted out regularly and thinly, but when I saw them the plants were out of flower. The variety was the common *Taraxacum officinale*, and seemed closely to resemble what Mr. Vilmorin, in "The Vegetable Garden," terms Very Early Dandelion. Probably good reasons can be given for the careful culture of these weeds at Kew in this way, but ordinarily they are a terrible pest.—D.

— **SWEET PEAS IN MAY.**—The value of Sweet Peas in May cannot well be overrated where cut flowers are much in demand. Their popularity, which is always of the fullest, is considerably extended when they are produced out of their ordinary season earlier or later. Our plants now in bloom were raised from seed sown in small 60-pots in January, and when they had made some growth were shifted into 5½-inch sizes, and stood on a shelf close to the glass, where the growth produced was sturdy and strong. Directly they began to "run" freely a narrow border at the back of a cool house was prepared by digging into the existing soil, which Tomatoes had previously occupied, some decayed manure. Some twiggy shoots of the Snowberry served as stakes, with the addition, when they had attained a good height, of string strained so as to keep them from falling about. Less than two dozen pots were thus treated, but many dozens of their sprays have already been gathered, and they certainly bid fair to continue until others forwarded in pots and planted in the open will be ready for gathering. They are particular favourites in the cut flower vases, in the house, and having space at command advantage was taken of it to obtain a lengthened season of their delicate coloured and sweetly scented blossoms. They are stimulated by liquid manure in weak doses, and are not allowed to suffer from want of root moisture. They stand about 7 feet in height, and are branching freely from almost every joint.—W. STRUGNELL, *Road Ashton Gardens.*

— **AN ODD COMBINATION.**—A large round clump of *Araucarias* at Kew, the trees, as all know, of the stiffest, most formal, and heaviest coloured description, had the other day a very beautiful carpet of blue *Scillas*. Nothing perhaps could be less in harmony than these two things, but the *Squills* are always beautiful, whether seen in woodland glades or in such quaint company as at Kew.—A.

— **THE MISTLETOE**, which has so long been shipped every year in such large quantities from France to England, will be more difficult to find next winter. That which was sent across the Channel came almost exclusively from the orchards of Normandy, where it flourished on the Apple trees. The French Government, says a daily contemporary, has decided that all the Mistletoe must be cut off the Apple trees at once on the ground that it sucks the sap of the trees and impoverishes them.

— **LAWNS AT THE IMPERIAL INSTITUTE.**—We take the liberty of directing your attention to the fact that the beautiful bright green lawns at the Imperial Institute were sown with our lawn seeds, and we shall be glad if you can find room for a notice respecting this in an early issue of your Journal.—SUTTON & SONS. [We have not had the pleasure of seeing these lawns, but the majority that have come under our notice in various parts of the country are disappointingly brown through the continued drought.]

— **COTONEASTER HORIZONTALIS.**—For training against a wall I know of no more charming plant than this, the natural growth of which lends itself so admirably to this purpose. It grows freely, although the foliage is small, and the growth is perfectly flat, each branch having a fan-like appearance. Established plants are now in bloom, with a profusion of miniature pinkish white flowers, probably to be followed by berries, but as I have not seen it in a berried state I am unable to say for certainty. It is, however, a plant to be sought after, and one of the most beautiful wall-covering shrubs we have.—W. D.

— **EVERLASTING PEAS.**—So much attention is given to the tall-growing forms of *Lathyrus*, that so pleasing a trailer as *Lathyrus hirsutus*, as seen on the rockwork at Kew, is frequently overlooked. That it does very well and is quite hardy is evident; growths range about 12 inches long, carrying small clusters of from three to four small flowers, the standards mauve and the tips nearly white. A pretty member of the Leguminose family, but stiffer in growth and rather more compact, is *Ononis rotundifolia*, quite a pretty perennial Vetch, flowers borne in small clusters, and of a reddish-pink colour.—D.

— **EARLY PEAS AND POTATOES.**—We gathered our first dish of Suttons' Ringleader Pea on the 15th inst., from seed sown in the open air on the 26th of January. This is the earliest date we have gathered Peas here during the last eighteen years. Chelsea Gem, sown at the same time side by side, will not be ready for another week. Veitch's Early Ashleaf Potatoes, planted out of a box between the Peas on the 7th of March, are now in flower, and will be ready for use next week. Laxton's Noble Strawberry, growing on a south border, will be ready in a few days. The Peas and Potatoes are growing on a border fully protected from the east winds.—J. SMITH, *Mentmore, Bucks.*

— **'CUTE SPARROWS.**—We hear a good deal about sparrows, and their ways; but our birds are behind the times in comparison with some over the water. An American paper says:—"A man fed his fowls upon rice, but, finding that the house sparrows dropped down in clouds and robbed the poultry of most of their food, determined to get the better of them, and substituted maize. He was astonished to observe that the sparrows, finding the grains too large to swallow, carried them to an adjacent railway line, and waited for the train to pass by, when they were enabled to pick up the crushed meal." "W. R. Raillem" would surely "hesitate to shoot" such smart birds as these.

— **CYRTODERA REFULGENS.**—When some of the Belfast florists were over here recently one of them in the flower market remarked that the only novelty he had seen there was this plant. That may have been an exaggeration, but doubtless market growers are much puzzled to find real novelties. I saw it growing largely in Messrs. Bruckhaus and Melling's little nursery at Twickenham the other day. The plants have a dwarf, somewhat creeping habit, throwing out runners like *Saxifraga tormentosa*, but the foliage is of a reddish velvety nature, and the flowers bright scarlet in colour and close set in the foliage, and not unlike those of a giant Musk in form. It makes a pretty basket or vase plant.—A.

— **WINTER COS LETTUCES.**—There seems even still to be some doubt as to the relative value of white and black-seeded Bath Cos Lettuces for winter work. Really both these varieties are suitable only for planting at the base of south or west walls in the autumn to stand the winter, as if some are to be wintered in frames any good white Cos is best. The white-seeded Bath Cos is perhaps the hardier, but is a spreading form that needs much tying. The black-seeded has darker leafage, and grows erect, hearting-in naturally. Probably a good stock of hardy Green Cos is as good as either of these for exposed winter growth.—D.

— **ROYAL BOTANIC SOCIETY.**—The second of the series of annual lectures given at the gardens of the Society took place May 12th, when Professor Groves, F.L.S., dealt in a popular manner with the "Life History of Ferns." Tracing the formation of Fern spores from the first slight swelling upon the under side of the mature frond, to the production of the perfect sori or case, with its countless dust-like spores, the lecturer briefly sketched their further development, first as small green leaf-like bodies lying flat upon the soil, through the subsequent formation and fertilisation of other spores arising from them, to the second and final birth of the infant Fern. This "alternation of generation," as it is called, is that which divides Ferns from flowering plants, for while true seeds when planted grow at once into the likeness of their parents, Fern spores have to pass an intermediate existence before they reach the same stage.

— **THE WAKEFIELD PAXTON SOCIETY.**—At a recent meeting of this Society Mr. Bott gave a very interesting paper on "Nature's Notes." At great length and with much lucidity he described the marvellous contrivances by which Nature effects the elaboration and protection of buds of various trees, and then expounded in detail the functions of leaves and flowers in the economy of plant life. Taking his audience on an imaginary rural ramble, Mr. Bott noted the wonderful wealth of vegetation that a grass field or a plantation possesses for the investigation of an observant eye, and remarked that our English woodlands and dales were not to be excelled or equalled in this respect even by tropical climes. All Mr. Bott's descriptions were clothed in graphic and poetic language, and evinced how keen an appreciation he has for the riches of our botanical surroundings, of which so many people are utterly oblivious.

— **DOUBLE PYRETHRUMS.**—Few plants requiring such simple culture are more useful and showy than these. Like the whole genus they will grow fairly well in almost any soil, but still they repay liberal treatment under such conditions. Their showy flowers come much finer, and the footstalks which support them are of greater length, while the Fern-like foliage is improved by growing stronger, and thus breaking away from the cushion-like form of weaker clumps. They look exceedingly well when planted either in beds, borders, or lines, and may be termed almost continuous summer bloomers, for if the flowers are cut for use as soon as they have expanded, or, when not required for that purpose, removed as soon as their beauty is over, others are quickly produced. When it is desirable to increase the stock the clumps should be lifted every alternate year in October or February, divided into pieces having two or three crowns and replanted. The following are excellent varieties:—Album plenum, white; Captain Nares, bright crimson; Dr. Livingstone, flesh colour; Duchess of Edinburgh, mauve; Marquis of Bute, reddish crimson; Mont Blanc, the best white; J. R. Tweedy, brilliant red; and Nancy, blush white, yellow centre.—H. D.

— **TULIPS AT KEW.**—Walking through Kew Gardens last week I noticed some brilliant beds of Tulips near the lake, and seeing that they were all named I began to take notes of the best, beginning with a couple of beds of mixed varieties, which, though getting over, were very beautiful. Then I stepped on to the grass to note *Tulipa micropelia*, rich purple scarlet; *T. fulgens*, having long broadly expanded pointed petals of a reddish crimson; and *T. spathulata*, not unlike *Gesneriana*, but larger, when I was hailed by a man wearing a uniform, and rudely told to get off the grass. I mildly remonstrated that as the Tulips were labelled for the information of the public I was but getting a few names. But no, off I had to come, although no notice was posted, so far as I saw, that I was interdicted from going on to the grass. I regarded the method of hailing me as most offensive, and would ask the Kew authorities to instruct their keepers to be rather more courteous, especially when they see anyone taking notes. A courteous remark that getting on to the grass there (it is not forbidden elsewhere in the gardens) was contrary to regulation would have been as courteously regarded.—A. D.

— **FLOWERS IN LONDON.**—Even in our smoke-begrimed city, and in quarters where one would least expect to see any such oases, one's eyes are gladdened every now and again by the sight of many a pleasant little garden plot that is nurtured by its owner with all the loving care that a resident in the suburbs bestows upon his little "estate." Only the other day, in a retired nook leading out of Bartholomew Close, says a correspondent in the *City Press*, I was shown quite a little picture in the way of cultivation. The plot in point is about 2 yards square, and is hemmed in on all sides with factories, and yet, thanks to the care the owner bestows upon it, the passer-by is given the sight of a thick clump of Lilies of the Valley, each plant being crowded with blooms. The cottages around are also gay with Pelargoniums and other plants that flourish under adverse circumstances.

— **THE WEATHER DURING APRIL AT RIPLEY, YORKS.**—April was a very bright dry month. There were twenty-two bright days; on four days the sun shone at intervals, and four dull days. The total rainfall amounted to 0.69 of an inch, which fell upon six days, the greatest daily fall being 0.26 on the 16th. Mean reading of barometer 30.26. Mean maximum temperature 59.6°. Mean minimum temperature 33.2°. Mean temperature of month 46.4°. Highest maximum temperature 75° on 24th, lowest minimum temperature 22° on 12th and 14th. As I write (May 11th) there is still no sign of the much-needed rain, and shallow-rooting subjects are quite at a standstill, though the deeper rooting occupants of plots and borders do not show any signs of suffering at present. Aphides are on Plums and Cherries, also caterpillars on Apricots and Pears are very abundant, entailing a deal of hand-picking and syringing with soapy water, else from their numbers they would have worked considerable mischief.—J. TUNNINGTON, *Ripley Castle Gardens*.

— **GRIMWOOD V. WEEKS.**—An action was brought in the Chancery Division on the 13th inst. by the executors of a deceased partner (Mr. George Deal) against the surviving partners, composing the firm of Messrs. J. Weeks & Co., Horticultural Builders, Chelsea, asking that the partnership affairs should be wound up. The object of the action was to ascertain what were the rights of the parties according to the true construction of a somewhat loosely drawn indenture deed. To this end several points were raised. The first was whether or not the defendants were entitled to take over the share of the deceased partner at a valuation. His Lordship said the matter seemed a somewhat complicated one. As the parties were agreed as to the amount of the share, why should they not settle by arbitration the amount payable, with interest at 5 per cent. on the first portion to run from the death of Mrs. Weeks in 1891? Mr. Chadwyck Healey stated the defendants would like to pay down the whole sum due. It was eventually agreed that an account should be taken of the deferred portion of the assets, with interest at 5 per cent. from the date of the death of Mrs. Weeks, to be paid within one month after the amount was ascertained, together with the sum due on the account to March 31st, 1885, with interest from the death of Mr. Deal, defendants to have liberty to pay not less than £2000 at any time; and no costs to be allowed on either side.

#### ORCHIDS AT MARK'S TEY.

MESSRS. FRED. HORSMAN & Co.'s Orchid nursery is situated near the station at Mark's Tey, a few miles from Colchester. The firm is specially celebrated for a fine strain of *Odontoglossum crispum*, collected under the supervision of Mr. John Carder, and as another consignment is to hand from him it is not surprising to find thousands of that species lying about the houses and packing sheds. Many of the masses are of an enormous size. Other imported Orchids in large numbers are *O. citrosimum*, *Lælia albida*, *Epidendrum vitellinum majus*, *Schomburgkia rosea* and *Chysis*.

The established plants are in a healthy condition. They are mostly in long, low, span-roofed houses, arranged on stages covered with coal ashes. The ventilation and shading appears to be perfect. Openings are provided in the walls for the air to enter beneath the stages both above and below the hot-water pipes. The shading is home-made, of lath, similar to the Parisian blinds. These are what

a writer described as the very worst kind of shading, but I have used them now continually for nearly twelve years, and consider them the best of all shading for Orchid houses. A nurseryman would not adopt them in preference to any other if they were not good.

Numerous plants are in flower, and others are approaching that stage, including some grand plants of *Cattleya Mendeli*, *C. Mossiæ*, and *Lælia purpurata*. An amateur would watch the expanding flowers of these with much interest, knowing that they all come from the best districts, and the majority have not bloomed before in this country. *Cattleya gigas*, *C. citrina*, *Lælia flava*, *L. furfuracea*, and *Dendrobium Jamesianum* are remarkable for fine healthy appearance, growing quite close to the roof glass. *Cattleya Aclandiae* is also at home under similar treatment. In one house is a fine collection of hardy *Cypripediums*. *C. acaule* is represented by many plants in full bloom, and specimens of *C. spectabile* are very strong, and will soon be in flower.

There are many valuable and rare species and varieties in this establishment, and a visit to Mr. Horsman's is enjoyable at any time. He has always something new or of interest to show, and to impart sound information to those who seek it.—G. W. CUMMINS.

#### NEW DENDROBIUMS.

**DENDROBIUM WARDIANUM ALBUM** obtained a first-class certificate recently, and deserved it. The pure white of the sepals and petals and the delicate markings of the lip, which had the yellow blotches, but only a faint indication of the maroon eye-like spots found in the type in a flower of full size, place this among the choicest of the forms of this fine species. It was shown by Mr. W. R. Lee of Audenshaw. *D. Bryan* was raised by Mr. Cookson from *D. luteolum* and *D. Wardianum*, and it obtained a first-class certificate when shown in flower. Mr. Cookson's hybrids are as a rule of first-rate merit, and this is no exception. It has slender stems 2 feet high, primrose coloured flowers

with purple tipped sepals, and a red-brown blotch and lines on the large lip.

*D. Sybil* is another of Mr. Cookson's hybrids, raised from *D. bigibbum* and *D. Linawianum*. It has the general habit of *D. nobile*, to which *D. Linawianum* is closely allied. The flowers have deep purple sepals, purple and white petals, the lip white, with blotches of

yellow and crimson. It obtained a certificate. *D. Benita*, a hybrid between *D. aureum* and *D. Falconeri*, was raised by Mr. Brymer, M.P. Its flowers, which are nearly 4 ins. across, are very similar to those of *D. Ainsworthi*, which was raised from the same parents.—W. WATSON (in *Garden & Forest*).

#### PHAIUS MACULATUS.

THIS is a most handsome *Phaius*, and one that is not so extensively grown as it might be. The illustration (fig. 72) portrays the beauty of *Phaius maculatus*. The flowers are from 2 to 3 inches across, of a soft yellow colour, except the middle lobe of the lip, which is marked with reddish brown, and they are produced in racemes of ten or twelve on scapes about 2 feet in height. In addition this *Phaius* has variegated foliage, the dark green leaves which are nearly 2 feet in length being spotted with yellow.

#### AERIDES PLATYCHILUM.

THIS distinct and pretty *Aerides* flowered with Mr. F. W. Moore, Glasnevin Botanic Gardens, Dublin, in April, 1892, when it was sent to Kew for determination. Nothing, says the "Kew Bulletin," is known of its native country. It

is allied to *A. Houlettianum*, *Rehb. f.*, having similar colours and a very sharply reflexed spur, but the lip is flat, not plicate, and the side lobes are free for less than half their length, not divided nearly to the base and spreading. The sepals and petals are light buff, with a faint purple stain near the tips. The lip is flat or slightly convex, pale yellowish white, the side lobes transversely barred with light purple, the front one with the middle and apex bright purple, and a few similar spots on the sides. The spur is buff pink. It is an interesting addition to the genus

FIG. 72.—PHAIUS MACULATUS.

## PORTSMOUTH CHRYSANTHEMUM SHOW.

WE have received the schedule of the next autumn Show, which opens on October 31st and closes on November 2nd. The Portsmouth shows of the past have been among the earliest, largest, and best in the kingdom, and the next may be expected to equal its predecessors. The leading class is the usual mixed, and of forty-eight blooms in thirty-six varieties, and the five prizes offered, of £10, £7, £5, £3, and £1 10s., should bring out good competition. The stands of single Chrysanthemums are invariably attractive at Portsmouth—the finest we have seen. The bunches are limited to three blooms. The fimbriate class is also effective, the blooms being arranged in the same way as singles. Good prizes are also provided for plants as well as in the fruit section of the Show. The Portsmouth November Shows are highly popular and attended by crowds of visitors. Mr. F. Power is the Honorary Secretary, and does all things well.

## SEASONABLE NOTES ON CHRYSANTHEMUMS.

THE majority of the plants for large blooms will now be occupying a position out of doors, although if it were possible I should prefer that they have the shelter of a cold frame for a couple of weeks yet; removing the lights entirely during fine and warm weather, but having them handy in case of frost, or cold east wind, where the plants are at all exposed to it. In my case it is necessary to provide temporary shelter by means of thatched hurdles for several weeks, while the wind remains in the east. Plants that are exposed are liable to have the foliage changed in colour to a pale hue by a prevalence of cold wind, which is not at all conducive to their welfare. This paleness in the colour of the foliage is very much aggravated if water is drawn direct from water companies' pipes, underground tanks, or wells, and given to the roots without first warming it, either by exposure to the sun in uncovered tanks or mixing with it hot water. It is surprising how quickly such an apparently small matter as the above will affect the colour of the leaves and with that the general health of the plants.

Plants grown without topping are now making what is known as the "first break," which is simply a transition from the singlestem to a new set of branches by natural means, caused by the formation of a flower bud at the point of the shoot, causing a temporary check to progress. This bud must be promptly removed and the requisite number of shoots selected, so that the whole energy of the plant will be concentrated in their progress for the future production of blooms. The orthodox number for each plant to develop thoroughly is three. In some instances where the blooms are small four are not too many, neither need the plants be restricted to less than three. It is at the "first break" stage that the number is decided upon, as but one to each shoot is allowed to develop; all surplus growth ought to be removed directly the most promising growths can be discerned. Some cultivators practise the topping plan on certain varieties and with very good results in the Japanese section, as for instance Mrs. Falconer Jameson, Mrs. Alpheus Hardy, and Stanstead White at times. The two former do not bloom quite at the right time in some districts, when managed on the orthodox method of allowing the plants to make their natural breaks. I would, however, caution cultivators with limited experience upon the topping principle. So much depends upon the weather that the plan is a risky one where the best results are desired. In the case of the incurved section I cannot advocate the topping principle at all. Plants require a longer season of growth in certain stages than the topping allows to enable the blooms to be developed deep and solid in "build." The recent hot weather has induced many plants to form flower buds too freely. The "Queen" family is particularly liable to this fault, so much so that many plants are rendered quite useless by the persistent manner in which the buds are formed, not only in the leading shoot, but the side branches are also affected in the same way. It is most difficult to account for this defect in culture beyond the reason given. The only remedy that I know of is to cut the plants down close to the soil with a view of inducing them to throw up another shoot. In many cases this will also set a flower bud before it is 6 inches long.

The plants are now in 5½-inch pots, and mainly are full of roots, quite ready for their final shift. Where a slight delay must take place before repotting can be done it is wise to supply the roots with weak liquid manure occasionally, with a view of stimulating the plants in the absence of more root space.

Preparing the soil for the last potting is a matter requiring some thought. No time should be lost in getting it ready, so that the manurial matter may thoroughly permeate through the whole of it. As a rule where bone manure is employed in the compost it is not mixed with the soil early enough to give off its manurial properties. Loam should form the principal ingredient, and it ought to be fibry. If it is taken from the surface of heavy land, partly decayed leaves, charcoal, wood ashes, and horse droppings ought to be freely used with a view to keeping the whole porous. Loam inclined to be sandy needs less of these materials, although wood ashes are good even for that class of

soil. Where turf is cut from poor land like that found on the downs in some districts it needs considerable assistance, either by the aid of animal or chemical manures. The latter may be used at the rate of from 2 lbs. to 3 lbs. to every bushel of compost, according to their individual strength.

A capital addition to poor turf is liquid manure, thoroughly saturating the turf some time before using it. Where obtainable cow manure in a half-decayed state is perhaps the best for light soil, horse manure being better for heavy loam as it tends to lighten it. Chrysanthemums require such a quantity of water at their roots during nearly all stages of their growth, that it is absolutely essential that the compost is made porous. Lime is necessary in some form or other, as soil deficient of calcareous matter is not likely to produce the best blooms. A handful of lime thrown on the turf occasionally when stacking it will not only supply a want, but is useful in destroying worms in the soil. Pounded oyster shells supply to an extent the want of lime in the soil. The turf I employ is wholly taken from a chalk subsoil, and to this fact—the presence of lime in quantity—I attribute the success in obtaining blooms of great depth and solidity.

Many persons make a mistake in the use of animal manures mixed with soil. It is too often the practice to advise the use of thoroughly decayed manure. This is wrong, because what beneficent properties can there possibly be in manure when decomposition has entirely taken place? The best way to prepare this manure is as if for a Mushroom bed, removing, of course, the greater part of the straw. It is sweetened, yet the ammonia is retained. To three parts of turf add one part of manure, half a part of decayed leaves, wood ashes and charcoal at the rate of one-sixth part, and artificial manure in addition at the rate named.—E. MOLYNEUX.

## THE GARDENING AND FORESTRY EXHIBITION.

## THE INAUGURAL CEREMONY.

IN beautiful weather the Gardening and Forestry Exhibition at Earl's Court was opened on Saturday, May 13th, by H.R.H. the Duke of York, K.G. As is usual on such occasions, the inaugural ceremony was of a brilliant character, the huge Exhibition buildings being most elaborately decorated. A large crowd assembled to meet the Royal visitor, who arrived about one o'clock, accompanied by General Sir Francis de Winton, the Marquis and Marchioness of Salisbury, the Thakûr and Rance Sahib of Gondal, the Lord Mayor of London and Lady Mayoress, and Cardinal Vaughan. The following, amongst other nobility and gentry, had also accepted invitations:—

The Marquis and Marchioness of Lothian, the Earl and Countess of Denbigh, the Earl of Haddington, the Earl and Countess Manvers, Viscount Powerscourt, Viscount Gort and Hon. Miss Vereker, the Lady Mayoress of Dublin, Hon. Mark Napier, M.P., and Mrs. Napier, Baron and Baroness de Reuter, Sir W. G. S. Vesey FitzGerald, Baron George de Reuter, Sir Richard Temple, M.P., and Miss Temple, Sir James Linton, P.R.I., Sir William Henry Flower and Lady Flower, Sir Charles Tupper and Lady Tupper, Sir Saul Samuel and Lady Samuel, Sir Charles Mills, Sir James F. Garrick and Lady Garrick, Lieut.-General Sir Andrew Clarke, Sir John C. Bray and Lady Bray, Sir Malcolm Fraser, Sir John Heron Maxwell and Lady Heron Maxwell, Sir Edward and Lady Braddon, Sir Algernon Borthwick and Lady Borthwick, Sir Walter Buller and Miss Buller, Sir Edmund Lechmere, M.P., and Lady Lechmere, Sir Joseph Hooker and Lady Hooker, Sir E. M. Shaw and Miss Shaw. Mr. H. E. Milner (Chairman of the Executive), Mr. Cadell (late of the Indian Forest Department), Mr. Harry Turner, and Mr. G. A. Loveday (Secretary) were also in attendance.

When the Duke of York reached the dais in the centre of building Mr. Milner advanced to the steps and read an address of welcome, in which the objects of the Exhibition were declared to be instructive and wholesome enjoyment, in which the study of forestry and gardening might be pursued amid such auxiliary attractions as good music and light and pleasant surroundings might afford. Reference was made to the sympathy which the Prince of Wales has shown in every movement conducive to the welfare and happiness of all classes, and there was much applause when Mr. Milner read the concluding words of the address, which alluded to the approaching marriage of His Royal Highness and Princess May.

The Duke of York in reply said: Mr. Milner, I thank you for your kind address, and I glad to come here to-day to open this Exhibition. It has for its object the instruction and enjoyment of all classes. The promotion of the love of gardening and the better knowledge of forestry are subjects of importance, and I am sure that your Exhibition will have a beneficial effect by drawing the attention of the public to these useful pursuits. I thank you for your kind allusion to my father, which I know will please him. In conclusion, I feel deeply touched by the congratulations you have offered me on my approaching marriage, and it is indeed a source of great gratification to both Princess May and myself that the announcement of our engagement has been so kindly received by all classes throughout the country.

A daughter of Mr. Dodson, of the Board of Directors, then came forward to present the Duke with a white Rose. Then the Prince passed through the great covered in garden which leads to the Exhibition grounds, and after a brief inspection of the flower Show, took his departure.

## THE FLOWER SHOW.

The majority of the exhibits at the special flower show, which was held in connection with the opening of the Exhibition, were staged in a

large marquee erected in the grounds. In many respects this is a decided improvement upon the arrangements that were made at the Earl's Court Exhibition last year, and the innovation was doubtless appreciated by the general public. It was not a large Show, although some good exhibits were staged, liberal prizes having been offered in the various classes.

Specimen plants were shown in excellent condition. Mr. F. Mould, Pewsey, Wilts, was first for nine stove and greenhouse plants, staging fine specimens of *Erica tricolor* Wilsoni, *E. ventricosa* magnifica, *E. Cavendishi*, *E. eximia* superba, *Bougainvillea glabra*, *Ixora Dixiana*, *Azalea Jean Vervaene*, *Hedera tulipifera*, and *Statice profusa*. Mr. H. James, West Norwood, second, and Mr. J. Currey, West End, Wilton Road, Salisbury, was awarded third prize. For nine fine-foliage plants Mr. Henry James was first. This exhibitor staged well grown *Crotons*, *Kentia Fosteriana*, *Dasylirotrichum*, and *Pandanus Veitchii*. Mr. J. Currey was second with fine plants, and Mr. J. F. Mould third.

Mr. Charles Turner, Royal Nurseries, Slough, was awarded first prize for a group of twenty-five *Roses*. The plants were well grown and splendidly flowered. The best varieties were *Maréchal Niel*, *Celine Forestier*, *Juno*, *Camille Bernardin*, *Madame de Montchaven*, *Charles Lawson*, and *Marie Baumann*. Mr. C. Turner was again first for twelve Show and Fancy *Pelargoniums*, the best being *Gold Mine*, *Alice*, *Phyllis*, *Ellen Beck*, *Duchess of Edinburgh*, and *Mrs. Hart*. Mr. J. Ford, gardener to Sir C. Pigott, Bart., Wrexham Park, Slough, was first for eighteen herbaceous *Calceolarias*. These plants were remarkably well grown and flowered. Mr. J. Mowbray, gardener to Major Hon. H. C. Legge, Fulmer, Slough, was second with grand plants. Messrs. B. S. Williams & Son were the only exhibitors of twelve *Amaryllises*, and were adjudged the first prize. The same firm exhibited a collection of *Clivias*, for which the premier award was adjudged. The best varieties were *Surprise*, *Cruenta*, *General Gordon*, *Princess May*, *Lindeni*, and *Ambrose Verschaffelt*. Mr. C. Turner was awarded first prize for a group of *Malmaison Carnations*, the plants shown being well flowered. Mr. Chas. Turner was also first in the class for eighteen greenhouse *Azaleas*, showing magnificent examples. Mr. H. James, Castle Nursery, West Norwood, was accorded second prize for a very creditable exhibit.

For a group of miscellaneous flowering and foliage plants Messrs. J. Laing & Son, Stanstead Nurseries, Forest Hill, were awarded the first prize for a beautiful arrangement including *Crotons*, *Caladiums*, *Clivias*, *Cattleyas*, *Gloxinias*, *Liliums*, *Begonias*, *Amaryllises*, *Odontoglossums*, *Cypripediums*, and *Cannas*. The second prize in this class was accorded to Messrs. B. S. Williams & Son, Upper Holloway, who exhibited *Anthuriums*, *Cattleyas*, *Azaleas*, *Odontoglossums*, and a splendid piece of *Cymbidium Lowianum*.

Bouquets and baskets of flowers made a good display in the Exhibition buildings. For three stands or vases of flowers and foliage Miss Mary Foden, Marlowe's Nursery, Hemel Hempstead, was accorded the first prize for a most charming and tastefully arranged exhibit. Miss Lilian Hudson, Gunnersbury House, Acton, was second; and Mr. F. W. Seale, Vine Nurseries, Sevenoaks, being third. Messrs. Perkins & Sons, Coventry, were, however, the leading exhibitors in the class for hand and brides' bouquets.

Miscellaneous exhibits formed a feature in the Show. Mr. Anthony Waterer, Knap Hill, Woking, sent a collection of *Azaleas*, well flowered. Messrs. R. Smith & Co., Worcester, had *Clematises* in pots, such as were staged at Crystal Palace, and which attracted much attention. Messrs. W. Paul & Sons exhibited a charming group of *Roses* in pots and cut blooms. Spenser, Merveille de Lyon, Clio, Lady Sheffield, and Zenobia were among the best of these. Mr. C. Turner sent specimens of his new *Rose*, "Turner's Crimson Rambler" well laden with blossoms. Messrs. T. S. Ware, Hale Farm Nurseries, Tottenham, arranged a fine group of hardy plants "not for competition." Amongst the most prominent of the plants in this exhibit were *Trollius giganteus*, *Spiræas*, *Delphinium nudicaule*, *Cypripedium acaulis*, *Primula Sieboldi*, *Pyrethrums*, and *Liliums*. Messrs. Collins Bros., Waterloo Road, S.E., also staged a group of hardy plants not for competition, which included *Pyrethrums*, *Lupinus*, *Irises*, *Aquilegias*, *Spiræas*, and *Liliums*. Messrs. Barr and Sons, Long Ditton, also had a large collection of hardy flowers in variety, which excited much interest amongst the visitors. Messrs. Cannell & Sons, Swanley, sent a group of *Begonias*, *Gloxinias*, tastefully arranged with Ferns; and Mr. W. Balchin, Hassocks Nurseries, Sussex, had a few plants of *Leschenaultia biloba* major. Mr. F. A. Morris, Church Road, Acton, was awarded a first-class certificate for a new dark *Coleus* named *Distinction*. Messrs. James Ford, Wexham Park, had a *Begonia* named *James Ford*; and Messrs. James & Sons, Farnham Royal, a group of *Calceolarias*. Messrs. Cutbush & Sons, Highgate, sent a large collection of hardy flowers; also a fine group of flowering and foliage plants.

Mr. G. Wythes, gardener to the Duke of Northumberland, Syon House, Brentford, arranged a fine group of plants "not for competition." The exhibits contained *Anthuriums*, *Palms*, *Cypripediums*, *Azaleas*, *Spiræas*, and *Crotons*. Mr. Wythes also staged a collection of fruit, including well grown examples of *Strawberry Augusté Nicaise*; *Grapes*, *Black Hamburg*, and *Foster Seedling*; *Brown Turkey Fig*, *Lord Napier Nectarine*, and *Monstera deliciosa*. Mr. J. Miller, gardener to Lord Foley, Ruxley Lodge, Esher, sent a collection of fruit and Cherries; and Messrs. J. Cheal & Sons, Crawley, Apples and other fruit and plants. Mr. A. Smith, High Wycombe, had cut *Roses* and *Pansies*.

#### THE GROUNDS AND GENERAL EXHIBITS.

A description of the Exhibition and the adjoining grounds was given in last week's issue of the *Journal of Horticulture*, and therefore it

would be superfluous to enter into details here. As previously stated, however, the Exhibition at that time was necessarily incomplete, and although much remains to be done yet the work of completion is being rapidly pushed on. So far as the gardening and forestry portions are concerned but little remains to be done, the grounds being planted in a most attractive manner.

The principal feature in this respect is doubtless, as was mentioned last week, the splendid covered-in garden. This is a grand example of indoor gardening. Huge banks and beds of *Rhododendrons*, planted by Messrs. W. Paul & Sons and Messrs. H. Lane & Sons, made a charming feature, the bright colours of the flowers contrasting admirably with the fresh green turf and winding gravelled walks. It is said that there are upwards of 2000 *Rhododendrons* in full bloom in this garden. A small group of a new *China Rose* named *Duke of York*, and a number of the recently introduced *Rose Princess May*, arranged by Messrs. W. Paul & Sons, naturally excited more than ordinary interest on the occasion of the opening ceremony. On one side of the main building is a magnificent fernery, which no visitor should miss. This rockery is splendidly constructed, and is planted with Ferns of various description, the scenic background being an admirable representation of Mr. Leopold Rothschild's garden at Ascott completes the arrangement.

Passing to the outside grounds the miniature fruit gardens designed and planted by Messrs. J. Cheal & Sons, Lowfield Nursery, Crawley, first meets the eye of the visitor. Here may be seen admirable examples of fruit growing on a small scale, and which also might be practised extensively. Cordon, pyramid, and standard Pear and Apple trees, also bush fruits are well represented, an archway covered with fruit trees being specially noticeable. Diamond-trained Currants and Gooseberries are also shown, and the majority of these are carrying a fair crop of fruit.

The beds and borders in various parts of the grounds are planted with shrubs and summer-flowering plants. Messrs. B. S. Williams and Sons fill some borders with *Zonal Pelargoniums* and other plants, whilst Mr. C. Turner, Slough, has planted a bed with *Fuchsias*, *Pelargoniums*, and *Cannas*. Miniature examples of forestry on light, medium, and heavy soils may also be seen. Messrs. C. Lee & Sons have rendered assistance in this department by planting shrubs and flowers. The examples of suburban gardening are deserving of more than a passing notice, and should prove instructive to amateurs.

With regard to the general horticultural exhibits in the main building these as yet are not very numerous. Messrs. Sutton & Sons, Reading, have a very interesting exhibit set forth in a tastefully designed show case, and is devoted principally to the display of vegetable, flower, and farm seeds. Models of vegetables, admirably executed and like-likeness in appearance, are also shown. There is also a collection of natural Grasses, whilst a series of coloured plates of Sutton's florists' flowers and a number of photographs of various departments of the vast seed establishment at Reading form a pleasing feature of their exhibit. Mention should also be made that the whole of the lawns of the Exhibition have been sown with Sutton's seeds. Messrs. F. Rosher & Co., Upper Ground Street, Blackfriars, S.E., are represented in various departments. They exhibit rustic summer houses, artistic in appearance and substantially built, greenhouses, statuary, and garden pottery in variety. The fountain in the main entrance hall is supplied by this firm. Conway G. Warne, Limited, Weston-super-Mare, also show garden pottery, Orchid pots, baskets, edgings, window boxes, vases, and statuary in excellent style. Similar exhibits are shown by Messrs. Pulham and Sons, Broxbourne, Herts. Other firms, it is believed, will also have stands of garden pottery, and these will be noticed at some future time. Mr. G. W. Riley, 81, Dulwich Road, Herne Hill, has examples of his skill in building summer houses and the manufacture of garden seats, rustic tables, and other ornamental sundries. These are represented in various designs, and should satisfy the tastes of the most fastidious.

Greenhouses and conservatories are not so plentiful as they were last year. Messrs. Mackenzie & Moncur, Edinburgh, have an ornamental conservatory, 16 feet by 10 feet, constructed, and drawings of horticultural appliances. Messrs. Sam Deards & Co., Limited, Eldon Street, E.C., exhibit plant houses and heating apparatus suitable for small and large structures. Chemical manures are shown by Messrs. R. Tons & Sons, Bow, E. Messrs. Chaffey Bros., Limited, 35, Queen Victoria Street, and of Melbourne, exhibit pictures and plans of fruit farms, vineyards, fruit sample cases, and other matters illustrative of the Australian irrigation colonies. Messrs. Ransomes, Sims, & Jefferies, Limited, Orwell Works, Ipswich, have a large and handsome display of their machines. Where a light machine is required for use by a boy, girl, or lady, or whether a heavier roller machine is desired, a selection may be made from this stand. This firm was awarded the gold medal for machines at the Exhibition last year.

The forestry section will be interesting to many, and is worthy of more than a brief notice such as must necessarily be given in the space at our disposal. Those who are interested in forestry, however, may with advantage spend a few hours in this department. Not the least important exhibit here is a collection of sixty varieties of Japanese woods sent by Major-General Sir R. Murdock Smith, Director, Museum of Science and Art, Edinburgh. A. E. Forbes, Esq., Bowood, Calne, Wilts, exhibits a dozen specimens of damage done to timber by insects and fungi; and J. A. Rutherford, Esq., Estate Office, Highclere Park, Newbury, has sent some fine Conifers grown on the Highclere estate. J. W. Forbes, Esq., Farnham Royal, Slough, exhibits specimens of fallen limbs from the Burnham Beeches, and W. Carruthers, Esq., a number of British woods grown in Windsor New Forest. W. Somerville, Esq.,

Durham College of Science, Newcastle-upon-Tyne, has specimens of forest trees damaged by insects, and F. Simmonds, Esq., Windsor Forest, a number of foresters' tools, models, and logs. The Tasmanian Government exhibit blocks of wood, and Sir James Campbell, Bart., Whitmead Park, Coleford, sections of trees and specimens of woodpeckers' operations on diseased trees in search of insects.

### CRYSTAL PALACE SHOW.

MAY 11TH AND 12TH.

BRIGHT sunny weather and good flower shows generally go hand in hand, and the same may be said of the summer Exhibition, which was held at the Crystal Palace on Thursday and Friday last. Beautiful weather prevailed, and there was a splendid display of plants and flowers. In the opinion of Mr. Head, the garden Superintendent, it was the finest Show held at the Palace for twenty years, and other experts corroborated this statement. It reminded one of the Exhibitions held two or three decades ago, and the most enthusiastic of plant growers must have been satisfied with the results. Specimen plants were magnificent, those staged by Mr. J. Cypher and other leading exhibitors being the best that have been seen in the metropolis for some time. Groups of Orchids and miscellaneous plants were also good, and the same applies to the Roses and hardy plants, the latter forming quite a feature. Bouquets and dinner table decorations were likewise well represented, and attracted the attention of visitors.

#### OPEN CLASSES.

The specimen plants in this section of the Exhibition were very fine. For twelve stove and greenhouse plants Mr. James Cypher, Queen's Road Nursery, Cheltenham, was deservedly placed first. The specimens shown by this exhibitor were splendidly grown, and comprised *Pimelea decussata*, *P. Hendersoni*, *Erica ventricosa coccinea minor*, *E. v. magnifica*, *E. Cavendishi*, *Fraxinea eximia*, *Anthurium Scherzerianum*, *A. Scherzerianum* Cypher's variety (grand), *Aphelaxis purpurea grandiflora*, *Azalea Neptune* (very fine), *A. Mademoiselle Van Houtte*, and *Bougainvillea glabra*. Mr. J. F. Mould, Pewsey, Wilts, was a good second. The best plants in this exhibit were *Statice profusa*, *Erica Cavendishi*, *Clerodendron Balfouri*, and *Bougainvillea glabra*. Mr. William Finch, gardener to James Marriot, Esq., Queen's Road, Coventry, was third, this collection including a splendidly grown *Azalea Mabel*. Greenhouse Azaleas were well represented. Mr. C. Turner, The Royal Nurseries, Slough, secured the premier position for nine plants, these being grandly flowered. The varieties were *Roi d'Hollande*, *Charmer*, *Jean Vervaene*, *Comtesse de Flandres*, *Etendard de Flandres*, *Reine des Pays Bas*, *Madame de Cannart d'Hamale*, *George Loddiges*, and *Due de Nassau*, the latter being specially fine. Mr. Albert Offer, Handcross Park Gardens, Crawley, was second with smaller specimens, and Mr. Henry James, West Norwood, third, the latter showing plants less formally trained.

Fine-foilage plants were quite as good as the flowering specimens. Mr. Albert Offer secured the premier position for nine plants. The specimens staged included *Asparagus plumosus nanus*, *Crotons Warreni*, *undulata*, *princeps*, *Alocasia macrorrhiza variegata*, and *Dieffenbachia magnifica* in first-rate condition. Mr. William Finch, Coventry, was second with grand examples, which included a magnificent and well coloured *Croton Disraeli*. Mr. H. James was third with smaller plants. Mr. Albert Offer also had the best nine stove and greenhouse Ferns, these being *Marrattia alata*, *Davallia polyantha*, *D. Mooreana*, *Cibotium Schiedeii*, *Alsophila excelsa*, *Nephrolepis davallioides furcans*, *Cyathea medullaris*, *Microlepia hirta cristata*, and *Alsophila australis*. Mr. W. Howe, gardener to Henry Tate, Esq., Park Hill, Streatham Common, was second, this including a well-grown *Goniophlebium subauriculatum*. Mr. A. Offer was also first for nine *Crotons*, showing grand plants of *Volutus*, *Chelsoni*, *undulatus*, *Nestor*, *Massangeanus*, *Weismanni*, *Queen Victoria*, and *picturatus*, all well coloured. Mr. H. James was second and Mr. J. F. Mould third. For twelve *Dracenas* Mr. J. Lambert, gardener to H. W. Segelecke, Esq., Effindale Lodge, Herne Hill, was first. The plants shown were well coloured. Mr. Henry James was second, and Messrs. J. Laing & Sons, third.

Orchids were shown in excellent condition both as specimen plants and in groups. Mr. Joseph Howes, gardener to W. Cobb, Esq., Silverdale Lodge, Sydenham, was awarded first prize for twelve Orchids in flower, showing well-grown specimens of *Odontoglossum Alexandræ*, *O. citreum*, *Cypripedium caudatum*, *Cattleya Mossiæ*, *Brassia verrucosa*, *Oncidium ampliatus majus*, *Masdevallia Harryana*, *Odontoglossum polyanthum*, *Phalaenopsis grandiflora*, *Cymbidium Lowianum*, and *Maxillaria Sanderiana*. Mr. H. James, Castle Nurseries, West Norwood, was awarded the third prize. Mr. J. Cypher, Cheltenham, secured the premier position for a group of Orchids arranged for effect. This was a grand feature in the Show, the plants being staged in a tasteful manner, *Cattleyas*, *Odontoglossums*, *Lælias*, *Oncidiums*, *Masdevallias*, all well blended with Palms, Ferns, *Caladiums*, and other foliage plants. Messrs. B. S. Williams & Sons, Upper Holloway, were second with a charming group, comprising many choice Orchids, and including a grand specimen of *Cymbidium Lowianum*.

Fancy Pelargoniums were good, although not very extensively staged. Mr. C. Turner, Slough, was placed first for nine plants, showing *Princess Teck*, *Phyllis*, *Mrs. Langtry*, *Mrs. Hart*, *Cloth of Silver*, *The Shah*, *Delicatum*, *Ambassador*, and *Fanny Gair* in splendid condition. Mr. Turner was also first for nine Show Pelargoniums, staging *Ed. Perkins*, *Alice*, *Mons. Des Moulin*, *Joe*, *Lady Isabel*, *Prince Leopold*, *Magpie*,

*Gold Mine*, and *Madame Thibaut*. There were no other exhibitors of these in this section. Mr. Henry Guyett, gardener to Thomas Gabriel, Esq., Elmstead, Leigham Court Road, Streatham, was first for eighteen *Calceolarias*, showing fine plants laden with flowers.

As already said, Roses formed a feature in the Show. Messrs. W. Paul & Son, Waltham Cross, were awarded first prize for eighteen Roses in pots. The varieties staged included *Caroline de Arden*, *Innocente Pirola*, *Mrs. J. Laing*, *Centifolia rosea*, *Madame Lacharme*, *François Levet*, *Leon Renault*, *Ella Gordon*, *La France*, *Edward Morren*, *Marguerite Romaine*, *Beauty of Waltham*, and *Magna Charta*. Mr. C. Turner, Slough, was second. Messrs. G. Paul & Son were adjudged the premier award for a group of thirty Roses in pots, showing well-bloomed specimens of bushes and standards.

The awards for groups of miscellaneous plants arranged for effect brought out several leading exhibitors. Messrs. J. Laing & Sons, Forest Hill, were first for a group not exceeding 200 square feet. This was arranged in their usual tasteful manner, and secured the admiration of many visitors. Orchids, *Begonias*, *Crotons*, Palms, *Gloxinias*, *Dracenas*, *Ericas*, and Ferns were included in the group. Messrs. J. Peed & Sons were second with an attractive group, and Mr. J. Currey, Wilton Road, Salisbury, third. Messrs. J. Laing & Sons also secured the leading place for a group of *Caladiums* which contained many choice varieties. Messrs. J. Peed & Sons were second.

Tuberous *Begonias* were not so plentiful as might have been expected. Mr. T. S. Ware was awarded first for twelve single varieties, the best being *Monarch*, *Blushing Bride*, *Avoca*, *Marginata*, *Sovereign* (good yellow), *Sunset*, *Novelty*, *Nerissa*, and *Champion*. Mr. T. S. Ware was also accorded first for twelve double *Begonias*, showing *Duke of Teck*, *Filberta*, *Duchess of Teck*, *Mrs. French*, *Bexley Gem*, *Brilliant*, *Princess May*, *Beauty of Belgrave*, in grand form. Mr. J. Lambert, Effindale Lodge, Herne Hill, was first for nine *Lycopods*, and Messrs. B. S. Williams & Sons first for twelve *Amaryllis*, the best of which were *Mrs. W. Lee*, *Dr. Masters*, *Chelsoni*, and *Comtesse de Germiny*.

For twelve plants suitable for dinner table decoration Mr. Charles Lane, gardener to E. H. Coles, Esq., Burntwood, Caterham, was first. The specimens shown included *Aralia Veitchi gracillima*, *Crotons picturatum*, *Aigburthensis*, *angustifolium*, and *Cyperus alternifolius variegata*. Mr. Thomas Macgregor, gardener to the Dowager Lady Hay, North House, Putney Hill, was second; and Mr. J. Portbury, gardener to W. N. Troy, Esq., Ripon House, Putney Heath, third.

There were three competitors in the class for "a collection of hardy herbaceous, bulbous, and alpine plants, distinct." This class must have given the judges much trouble, owing to ambiguity of the wording of the schedule. The first prize exhibit, staged by Messrs. Collins Bros., perhaps contained a greater number of kinds of hardy flowers, thus being more complete as a "collection;" but the group staged by Mr. T. S. Ware, to whom the second prize was adjudged, was certainly "distinct" and the most effective. Messrs. G. Paul & Sons were third. Violets and Pansies were not particularly good. Messrs. W. Paul and Sons were awarded second prize for twenty-four *Violas* in pots, and Mr. A. Smith, Prospect House, Downley, High Wycombe, third for twenty-four Pansies in pots. Mr. C. Turner was the only exhibitor of twenty-four *Auriculas*, and also eighteen greenhouse Azaleas.

The bouquets, baskets of flowers, and dinner table decorations were very fine. Messrs. Perkins & Sons, Coventry, were first for a basket of flowers. This was comprised of *Cattleyas*, *Lælias*, *Odontoglossums*, *Lily of the Valley*, and *Maréchal Niel* Roses, with *Asparagus plumosus nanus*, and *Adiantums*. Messrs. Harwood Bros., Balham Nursery, Balham, were second; and Mr. Thomas Horsman, Clock House Nursery, Beckenham, third. Mr. F. W. Seale, Vine Nursery, Sevenoaks, was first for dinner table decorations, which had a bright and charming effect. Miss Mayhew, South Norwood Hill; and Mrs. Walter Mole, 22, High Street, Hemel Hempstead, were adjudged equal third prizes. For three stands or vases of flowers and foliage suitable for dinner table, Mr. W. Clark, Balham, was first; Mr. Seale, second; and Mr. Horsman, third. Messrs. Perkins & Sons were first for one bouquet (brides'); Messrs. Peed & Sons being second, and Mr. J. Prewett, Swiss Nursery, Hammersmith, third. Messrs. Perkins & Sons were also first for three bouquets; Mr. F. Seale being second. Messrs. Perkins were again first for six dress bouquets or sprays; Mr. T. Horsman second, and Mr. W. Acland, Crystal Palace, third.

In the cut flower section Messrs. G. Paul & Sons were awarded first prize for a collection of hardy flowers and shrubs arranged with foliage. Mr. W. Finch, Coventry, secured first prize for twenty-four varieties of stove and greenhouse flowers. Mr. A. Gibson, gardener to J. F. Burnaby-Atkins, Esq., Halstead Place, Sevenoaks, was second; and Mr. C. Lane, Caterham, third. Mr. J. Douglas, gardener to Mrs. Whitbourn, Great Gearies, Ilford, was first for twelve varieties of cut Orchids; and Mr. J. Prewett, Swiss Nursery, Hammersmith, being second.

#### AMATEURS' CLASSES.

Most of the amateurs' classes were fairly well filled, and some fine plants were staged. For six Palms Mr. W. Howe, Park Hill, Streatham, was first, showing grand specimens. Mr. W. Finch was second, and Mr. Albert Offer third. Mr. Offer had the best six *Dracenas* in this section; Mr. W. Carr, gardener to Mrs. Stephenson Clarke, Croydon Lodge, Croydon, taking a second honour. Mr. W. Finch had the best six fine-foilage plants, which included a splendid *Latania borbonica*. Mr. Albert Offer was second, and Mr. J. Currey was third. For six *Crotons* Mr. W. Howe was first with well coloured specimens.

Mr. W. Chapman, gardener to J. Spode, Esq., Hawkesyard, Staffs, had the best six stove and greenhouse plants, showing *Aphelaxis*

grandiflora, *Statice profusa*, *Ericas ventricosa coccinea minor*, *Ixora Dixiana*, and *Anthurium Scherzerianum* in splendid condition. Mr. Albert Offer was second, and Mr. J. Currey third. Mr. J. Douglas was first with six exotic Orchids. Mr. J. Howes, gardener to W. Cobb, Esq., Silverdale Lodge, Sydenham, was second, and Mr. W. Finch third. Mr. James Portbury, gardener to W. N. Troy, Esq., Ripon House, Putney Heath, was the principal exhibitor with Begonias in this section. Calceolarias were best shown by Mr. J. Douglas, Mr. Henry Guyett, and Mr. J. Bateman, gardener to Mrs. King, Southwood, Sydenham Hill. Mr. Charles Boatwright, gardener to E. Covell, Esq., Beckenham, was first with six Caladiums, showing fine specimens. Mr. J. Day, gardener to W. S. Gover, Esq., Casino House, Herne Hill, was second, and Mr. F. Lambert third. Mr. J. Douglas was first with six stove and greenhouse Ferns, Mr. Boatwright being second. Mr. W. Carr was awarded second prize for six greenhouse Azaleas in bloom.

#### MISCELLANEOUS.

These were numerous and of a varied character. Messrs. B. S. Williams & Sons staged Otaheite Oranges laden with fruit, and Mr. C. Turner sent plants of his new Rose Turner's Crimson Rambler. Messrs. J. Laing & Sons sent a small collection of *Streptocarpus*, *Dracenas*, *Crotons*, and *Palms*. Messrs. W. Paul & Sons had a grand group of Roses in pots and some boxes of cut blooms. Messrs. Richard Smith & Co., St. John's Nurseries, Worcester, sent fine specimen Clematises in pots. Mr. W. Rumsey, had several boxes of cut Roses. Mr. H. J. Jones, Hither Green, Lewisham, had a grand collection of Pelargoniums in flower, and Mr. T. S. Ware, Tottenham, sent Tuberous Begonias in great variety. Messrs. Cutbush & Sons, Highgate, staged a group of miscellaneous plants; as also did Messrs. Peed & Bornemann, Sydenham. Mr. W. Leaking, Upper Norwood, sent some well grown Gloxinias. Messrs. W. Balchin & Sons, Hassocks Nursery, Sussex, staged a small group of *Leschenaultia biloba major*. A new Cucumber named Self's Prickly Pre-eminent was staged by Mr. F. G. Self, The Grange, Lower Sydenham; and Mr. Hardy, Parson's Green, sent a collection of Mushrooms. Extra prizes were awarded for the majority of these miscellaneous exhibits.

First-class certificates were awarded to Mr. Chas. Turner, Slough, for Polyantha Rose Turner's Crimson Rambler; Messrs. J. Peed & Sons, West Norwood, for Caladium Comtesse de Brosse; Mr. H. J. Jones, Lewisham, for Ivy-leaf Pelargonium Ryecroft Surprise; Messrs. Wm. Paul & Son, Waltham Cross, for Rose Clio; Mr. T. S. Ware, Tottenham, for Begonias Bexley Gem, Picotee, and Messina, also Border Carnation Pride of Great Britain; Messrs. Paul & Son, Cheshunt, for Herbaceous Phlox G. F. Wilson; and Messrs. J. Laing & Sons, Forest Hill, for Caladium Mons. Leon Saye, and Begonias Lady Brooke, Earl of Craven, and Lady Dunsany.

#### ARNICA MONTANA.

THIS is a plant that is worthy of more attention, as it is now comparatively neglected or confined to botanic gardens. On a rockery it has a pretty appearance, its bright orange yellow flowers being freely produced, and at Kew it is usually attractive at this time of the year. Of the ordinary shades of yellow we have abundant floral representatives, but a pure orange is not so frequently seen, and contrasts with many other colours very effectively.

#### ROYAL HORTICULTURAL SOCIETY.

MAY 9TH.

SCIENTIFIC COMMITTEE—Present: Mr. McLachlan (in the chair); Rev. W. Wilks, Mr. Blandford, Professor Müller, Dr. Bonavia, and Rev. G. Henslow, Hon. Sec.

*Myosotis alpestris*, multipetalous var.—The plants brought to the last meeting by Dr. Bonavia proved to be the same as that described and figured in the *Gardeners' Chronicle* (August 8th, 1891, p. 159), where it is stated that "According to M. Ernst Benary of Erfurt, who sent it out in 1886, it was raised in Germany, and is 'presumed to have sprung' from *M. alpestris*, robusta, grandiflora (Eliza Fourcort). It was fully described in M. Benary's list of novelties in 1886. He adds, 'It comes quite true from seed.'" Mr. Appleton of Sipson near Slough writes that he has grown some acres of it for five or six years, and always from seed, about 80 per cent. coming true. The name by which it is generally known is "Victoria," but Messrs. Carter are issuing seed for 1893, under the name of "The Jewell." It appears to be quite hardy, withstanding severe winters without any protection. A botanical description is given in the *Gardeners' Chronicle*, where it is called the "Hen and Chickens" Forget-me-not, as the flowers on the central axis terminate in a synanthic condition, while numerous scorpioid racemes radiate from below it. The stems are often strongly fasciated. With regard to the separate multipetalous flowers, Dr. Bonavia contributed the following additional observations:—"I have no doubt whatever that this monstrous form does seed, and for the following reasons:—(a) The pistil is conical, like the neck of a bottle in the middle of a circle of nucules; and the stigma is well formed, consisting of six or seven lobes, often covered with pollen. (b) When the corolla had fallen off for some time the stigma is shrivelled, and several of the nucules are much larger than their companions, indicating that their contents had been fertilised. I have two forms before me—one of a turquoise blue with all the flowers

elongated, and with an oval centre; the other is much paler, and with all its flowers circular, the centre being also circular. Both varieties have eight, nine, or ten petals and stamens." A further examination of the pistils made by Mr. Henslow reveals that either another pistil or a cluster of stamens may be found within the ovary. In the last report a number of free central ovules was described; but as this observation has not been confirmed, they were probably rudimentary papillæ of undeterminable character. On removing an ovule from a nucule it is found to be oval, with a remarkably long "beak" turned towards the funicle. Many consisted of a hollow bag-like structure, being presumably the primine only. Those which had become larger proved to possess pro-embryos, while the fully formed nucules, with black polished surfaces of the "seeds" issued by Messrs. Carter, had large, perfect, oily

FIG. 73.—ARNICA MONTANA.

embryos. The thanks of the Committee were given to Dr. Bonavia and Mr. Henslow for their investigations into the structure of this remarkable variety.

*Sugar-cane Moth*.—Mr. Blandford exhibited specimens received from Mr. Morris of moths, the caterpillars of which attack the Sugar-canes in Teneriffe. It appeared to be a variety of or perhaps a different species to *Diatraea saccharalis*, which bores into the Maize stems, from which it is said to have spread to the Sugar-canes. It was first figured by Rev. L. Guilding in the "Trans. Soc. of the Encouragement of Arts," 1828, vol. xvi., p. 149 (*D. sacchari*, Guild). It is also figured and described as the "Larger corn stalk-borer" by Mr. L. O. Howard, "Insect Life," p. 95 (*D. saccharalis*, F.). Washington 1891.

*Scale-insect on Retama*.—Mr. McLachlan exhibited specimens from Mr. Morris, the plants growing from 7-8000 feet on the Peak of Teneriffe. It proved to be *Mytilaspis pomorum*, the Apple-tree scale insect. It was first described as occurring in N. America. It subsequently appeared in Guernsey. It has also been found on the Broom, which is closely allied to Retama.

*Euonymus Attacked by Caterpillars*.—Specimens of the common Spindle tree, infested with the web-forming *Hyponomeuta evonymella*

were sent from Battersca Park, where they are described as doing great damage both to the deciduous and evergreen (Japanese) species of *Euonymus*. Another species is also attacking the Hawthorns. The best remedy is spraying the trees with some insecticide, as—e.g., 6 ozs. of Paris green dissolved in 100 gallons of water.

*Aquilegia*, var.—Mr. E. J. Low, of Shirenewton, Chepstow, sent examples of the dark crimson Columbine "Royal Marriage" without the usual spurs; a not uncommon variety, exhibiting a reversion to the presumed ancestral form.

## EXHIBITION AT THE MOSELEY BOTANICAL GARDENS, BIRMINGHAM.

THE first of a series of horticultural exhibitions was held here on the 10th and 11th inst., and was devoted chiefly to artistic floral work, such as wreaths, crosses, epergnes, and baskets of flowers, and a separate class for group of floral designs, at the discretion of the exhibitor, in a space 9 feet by 4 feet. Messrs. Perkins & Sons, Coventry, won the large gold medal for a wonderfully fine display of exquisite artistic work, no less than thirty-six objects being staged, including many charming shower bouquets of various materials, baskets and other designs. It was a grand display, and was much admired. Messrs. Pope & Sons, nurserymen, Birmingham, won the second gold medal for also a very fine display, and Mr. Thewles, florist, Birmingham, a large silver medal for white wedding shower bouquets, consisting of white flowers and silvered fronds of Ferns and Grasses, a new process. These were very handsome, as were some bridal fans. Messrs. Perkins & Sons were first for a wreath, a bride's bouquet, a bridesmaid's bouquet, and a massive large cross, but were very closely run by Messrs. J. R. Pearson and Sons, Chilwell Nurseries, Nottingham, with a very handsome arrangement.

Another class was devoted to groups of cut flowers, any kinds, in a space 6 feet by 3 feet, and Messrs. Pope & Sons were first with a fine display, and Mr. Clements, gardener to Mrs. Horton, second.

Some fine groups of plants were arranged in competition, and Messrs. Hewitt & Co., nurserymen, staged a fine group of plants, in which were masses of *A. F. Barron*, *Volunté Nationale alba*, and *Jubilee Pelargoniums*, also a number of cut hardy flowers. Some wonderfully fine Mushrooms were staged by the gardener at Moseley College, so fine indeed that a silver medal was awarded to them.

## ROYAL NATIONAL TULIP SOCIETY.

MAY 13TH.

THE annual Exhibition of this Society was held at the Manchester Botanical Gardens, Old Trafford, Manchester, on Saturday last. The date originally fixed was the 23rd of May, but the hot forcing weather of the last few weeks made it necessary to alter the date to the 13th; and although this date is the earliest date on record for the National Tulip Show, yet the blooms of some growers—for instance, of Messrs. Horner, Haynes, and Thurstan—was past, and they were unable to exhibit. On the other hand, the Wakefield growers wanted the Show to be held on the 23rd, as originally fixed, as their Tulips were not in good bloom. Still the Show was the best held for several years, and all the classes were keenly contested. There were few notable novelties shown. Amongst little-known flowers we noted "Dr. Hutcheon," a magnificent flamed bizarre, raised by the late Mr. Storer. This variety, if a good grower, bids fair to challenge Sir Joseph Paxton, whose right to be considered the best Tulip grown has been undisputed forty years. "Lord Frederick Cavendish," a Yorkshire flower, is a most welcome and valuable addition to the red-feathered bizarre class. "Bertha" was a first-rate feathered bybloemen, the colour is, however, rather rosy; and Clio, a large flamed darkish rose, was very striking. Many old kinds were shown in fine style, and it was rather startling to find in the stand of twelve that won the silver cup such veterans as Lord Lilford, Duke of Devonshire, Aglaia, and Bienfait. Amongst the usual kinds Sir Joseph Paxton, Aglaia, Duchess of Sutherland, Masterpiece, and Talisman were in good style; and Chancellor, often so disappointing, was a noble flower. There was a stiff competition for the "cup" class, nine stands of twelve being staged. The Judges were Messrs. Woodhead, of Staleybridge; Keysey, of Gorton; and the veteran Mr. J. Dicken, of Hurst. The following is a list of the awards:—

### RECTIFIED TULIPS.

Class 1.—Twelve dissimilar Tulips, two feathered and two flamed in each class.

First, Mr. W. Kitchen of Marple with flamed bizarres, Sir Joseph Paxton and Duke of Devonshire (fine); flamed bybloemen, Chancellor (excellent) and Adonis; flamed roses, Clio and an unnamed variety; feathered bizarres, Lord Lilford (rather greasy base) and Masterpiece; feathered bybloemen, Violet Amiable (fine) and Bienfait (perfectly pure); feathered roses, Minerva (bad shape) and Julia Farnese.

Second, Mr. S. Barlow, Stakehill, with flamed bizarres, Prince of Wales (fine), Lord Stanley (excellent); flamed bybloemen, Talisman (very good) and Friar Tuck; flamed roses, Aglaia and Madame St. Arnaud; feathered bizarres, Garibaldi (very fine) and Masterpiece; feathered bybloemen, William Parkinson (beautiful) and Violet Amiable; feathered roses, Modesty and Madame St. Arnaud.

Third, Mr. J. W. Bentley, Stakehill, with flamed bizarres, Dr. Hutcheon (fine), and Sir Joseph Paxton; flamed bybloemen, Ashmole's

114 and Talisman (very good); flamed roses, Annie McGregor and an unknown variety; feathered bizarres, William Wilson (good) and Sir Joseph Paxton; feathered bybloemen, King of the Universe and Friar Tuck; feathered roses, Julia Farnese and Heroine.

Fourth, Mr. John H. Wood, Royton, with flamed bizarres, William Lea and Sir J. Paxton; flamed bybloemen, Chancellor and Lord Denman; flamed roses, Annie McGregor and Mabel; feathered bizarres, Sulphur (fine) and Masterpiece; feathered bybloemen, Bessie and Violet Amiable; feathered roses, Modesty and Mabel.

Fifth, Mr. C. W. Needham, Royton, with flamed bizarres, Dr. Hutcheon (a grand flower) and Sir J. Paxton; flamed bybloemen, Duchess of Sutherland and Lorenzo; flamed roses, Aglaia and Annie McGregor; feathered bizarres, Wm. Wilson (very fine and large); feathered bybloemen, Elizabeth Pegg and Mrs. Lymbery (poor); feathered roses, Mrs. Atkin and Modesty.

Class 2.—Six dissimilar Tulips, one in each class. In this class there were twelve competitors.

First, Mr. J. W. Bentley, with an excellent stand, comprising Sir Joseph Paxton (extra good), flamed bizarre; Lord Frederick Cavendish (fine), feathered bizarre; Chancellor (very good), flamed bybloemen; Mabel, flamed rose; Modesty, feathered rose; and Elizabeth Pegg (very fine), feathered bybloemen.

Second, Mr. S. Barlow, with Sir J. Paxton, flamed bizarre; Friar Tuck, flamed bybloemen; Annie McGregor, flamed rose; Mrs. Cooper (beautiful), feathered bybloemen; Sarah Headley, feathered rose; and Garibaldi, feathered bizarre.

Third, Mr. W. Kitchen, with Sir J. Paxton, flamed bizarre; Duchess of Sutherland, flamed bybloemen; Triomphe Royale, flamed rose; Lord Lilford, feathered bizarre; Violet Amiable, feathered bybloemen; and Mabel, feathered rose.

Fourth, Mr. J. Jones, Denton, with Sir J. Paxton, flamed bizarre; Lord Denman, flamed bybloemen; Mabel, flamed rose; Sir Joseph Paxton, feathered bizarre; Modesty, feathered rose; and Bertha (a beautiful flower), feathered bybloemen.

Fifth, Mr. W. Dymock of Stockport. Sixth, Mr. J. H. Wood. Seventh, Mr. C. W. Needham. Eighth, Mr. A. Moorhouse, Wakefield.

Class 3.—Six dissimilar Tulips, one feathered and one flamed in each class (for small growers only).

First, Mr. H. Gill, Leeds, with Sir J. Paxton, flamed bizarre; Mabel, flamed rose; Bessie, flamed bybloemen; Lord Frederick Cavendish, feathered bizarre; Mrs. Gill, feathered bybloemen; and Heroine, feathered rose.

Second, Mr. John Hayes, Bedford Leigh, with Sir J. Paxton, flamed bizarre; Chancellor, flamed bybloemen; an unknown flamed rose; Sir Joseph Paxton, feathered bizarre; Violette Amiable, feathered bybloemen; and Industry, feathered rose.

Class 4.—Three feathered Tulips. First, Mr. J. W. Bentley, with Guido, Rosetta, and Masterpiece. Second, Mr. J. H. Wood, with Bessie, Annie McGregor, and W. Wilson. Third, Mr. W. Kitchen, with Violet Amiable, Compté de Vergennes, and King. Fourth, Mr. C. W. Needham, with Carbuncle, Mabel, and Magnum. Fifth, Mr. J. Jones. Sixth, Mr. Moorhouse.

Class 5.—Three flamed Tulips. First, Mr. W. Kitchen, with Lord Denman, Clio, and Willison's King. Second, Mr. J. H. Wood, with Lord Denman, Mabel, and Sir J. Paxton. Third, Mr. J. Hague, Stockport, with Norval, Triomphe Royale, and Sir J. Paxton. Fourth, Mr. S. Barlow, with Martin's 101, Mabel, and Masterpiece. Fifth, Mr. W. Prescott. Sixth, Mr. J. W. Bentley.

Class 6.—Two Tulips one feathered and one flamed of any class. For maiden growers only. First, Mr. H. Gill, with Sir Joseph Paxton and Masterpiece. Second, Dr. W. Pegge (Beeston, Notts), with Elizabeth Pegg and Sir J. Paxton. Third, Messrs. Stuart & Mein, Kelso, with Carbuncle and Masterpiece.

Class 7.—Two Tulips, one feathered and one flamed of any class. First, Mr. H. Gill, with Sir J. Paxton flamed, and Masterpiece feathered. Second, Mr. W. Dymock, with Sir J. Paxton flamed, and King of the Universe feathered. Third, Mr. S. Barlow, with Dr. Hardy flamed, and Sir S. Romilly feathered. Fourth, Mr. W. Kitchen, with Prince of Morocco flamed, and Violet Amiable feathered. Fifth, Mr. J. H. Wood. Sixth, Mr. W. Prescott.

Class 8.—Single blooms. Feathered bizarres.—First, Mr. Moorhouse, with John Ratcliffe; second, Mr. Jones, with Sir J. Paxton; third, Mr. Moorhouse, with Masterpiece; fourth, Mr. Bentley, with Wm. Annibal; fifth, Mr. Kitchen, with Sulphur; sixth, Mr. Barlow, with Hepworth's 34/64 seedling; seventh, Mr. Bentley, with Lord Stanley; eighth, Mr. Barlow, with Richard Yates; ninth, Mr. Barlow, with General Grant; tenth, Mr. Wood, with Emperor Nicholas.

Feathered roses.—First, Mr. Bentley, with Julia Farnese; second, Mr. Moorhouse, with Mrs. Lea; third, Mr. Barlow, with Annie McGregor; fourth, Mr. Kitchen, with Alice; fifth, Messrs. Stuart & Mein, with Sarah Headley; sixth, Mr. Kitchen, with Modesty; seventh, Messrs. Stuart & Mein, with Mrs. Atkin; eighth, Mr. Kitchen, with Compté de Vergennes; ninth, Mr. Kitchen, with Clio; tenth, Mr. Barlow, with Owl.

Feathered bybloemen.—First, Mr. Barlow, with Violet Amiable; second, Mr. Bentley, with Bessie; third, Mr. Barlow, with Adonis; fourth, Mr. Jones, with Bertha; fifth, Mr. Kitchen, with Violet Amiable; sixth, Mr. Kitchen, with Bienfait; seventh, Mr. Bentley, with Bacchus; eighth, Mr. Barlow, with Wm. Parkinson; ninth, Mr. Dymock, with John Hart; tenth, Mr. Dymock, with King of the Universe.

Flamed bizarres.—First, Mr. Barlow, with Sir J. Paxton; second, Mr. Dymock, with Sir J. Paxton; third, Mr. Dymock, with Dr. Hardy; fourth, Mr. Kitchen, with Masterpiece; fifth, Mr. Barlow, with Lord Stanley; sixth, Mr. Bentley, with William Wilson; seventh, Mr. Kitchen, with San José; eighth, Mr. Bentley, with Sulphur; ninth, Mr. Hayes, with Orpheus; tenth, Mr. Bentley, with Duke of Devonshire.

Flamed roses.—First and second, Mr. Kitchen, with Aglaia; third, Mr. Hague, with Mabel; fourth, Messrs. Stuart & Mein, with Triomphe Royale; fifth, Mr. Bentley, with Lady C. Gordon; sixth, Mr. Prescott, with Annie McGregor; seventh, Mr. Kitchen, with Clio; eighth, Mr. Bentley, with Lea's Seedling; ninth, Mr. Hague, with Madame St. Arnaud; tenth, Mr. Dymock, with a seedling.

Flamed bybloemens.—First, Mr. Kitchen, with Chancellor; second, Mr. Kitchen, with Duchess of Sutherland; third, Mr. Prescott with Bion; fourth, Mr. Barlow, with Friar Tuck; fifth, Mr. Barlow, with Maid of Orleans; sixth, Mr. Kitchen, with King of the Universe; seventh, Mr. Barlow, with Talisman; eighth, Mr. Jones, with Maid of Orleans; ninth, Mr. Dymock, with Lord Denman; tenth, Mr. Kitchen, with an unnamed variety.

The prize for the best feathered Tulip in the whole Exhibition was given to Mr. Jones for the bloom of "Bertha," feathered bybloemen, exhibited in his stand of six flowers; and the prize for the best flamed flower in the Exhibition was given to Mr. Bentley for the Sir Joseph Paxton flamed bizarre in his stand of six flowers.

#### BREEDER TULIPS.

Breeder Tulips were exhibited in good numbers, and were remarkably fine; they were a beautiful feature in the Exhibition.

Class 10.—Six dissimilar breeder Tulips, two in each class. First, Mr. Bentley, with Sir Joseph Paxton and Goldfinder, bizarres; Glory of Stakehill and Wm. Parkinson, bybloemens; Mrs. Barlow and Madame St. Arnaud, roses. Second, Mr. Barlow, with Sir Joseph Paxton and Goldfinder, bizarres; Miss B. Coutts and Rose Hill, roses; Alice Grey and Glory of Stakehill, bybloemens. Third, Mr. J. Hague, with Alice Grey, Mrs. Barlow, Jeanette, and three unnamed varieties. Fourth, Mr. Needham, with Criterion and Paxton, bizarres; Annie McGregor and Mabel, roses; Martin's 117 and an unknown, bybloemens. Fifth, Mr. Kitchen. Sixth, Mr. Jones.

Class 11.—Three breeder Tulips, one in a class. First, Mr. Barlow, with Miss B. Coutts, Sir Joseph Paxton, and Glory of Stakehill. Second, Mr. Kitchen, with Annie McGregor, Sir J. Paxton, and seedling. Third, Mr. Hague, with Annie McGregor, J. Wilkinson, and Alice Grey. Fourth, Mr. Bentley, with Olivia, Lord F. Cavendish, and Glory of Stakehill. Fifth, Mr. Dymock. Sixth, Mr. Gill. Seventh, Mr. Moorhouse. Eighth, Mr. Wood.

Class 12.—Single blooms, bizarre breeders. First, Mr. Barlow, with Goldfinder; second, Mr. Barlow, with Sulphur; third, Mr. Prescott, with Sir J. Paxton; fourth, Mr. Barlow, with Horatio; fifth, Mr. Dymock, with Dr. Dalton; sixth, Mr. Bentley, with Richard Yates; seventh, Mr. Barlow, with Criterion; eighth, Mr. Bentley, with Dr. Hutcheon.

Rose breeders.—First, Mr. Kitchen, with Olivia; second, Mr. Barlow, with Miss B. Coutts; third, Mr. Kitchen, with Rose Hill; fourth, Mr. Barlow, with Olivia; fifth, Mr. Prescott, with Mrs. Collier; sixth, Mr. Kitchen, with Countess of Burlington; seventh, Mr. Barlow, with Annie McGregor; eighth, Mr. Gill, with Madame St. Arnaud.

Bybloemen breeders.—First, Mr. Barlow, with Adonis; second, Mr. Bentley, with Ashmole's 126; third, Mr. Barlow, with Glory of Stakehill, fourth with Ashmole's 114, fifth with Martin's 117, sixth with Elizabeth Pegg, seventh with Hepworth's 164/65, and eighth with Agnes.

The prize for the best breeder Tulip in the Exhibition was awarded to Mr. Barlow for the bloom of Goldfinder, exhibited in class 12.

#### ROYAL BOTANIC SOCIETY.

MAY 17TH.

THE summer Exhibition of the Royal Botanic Society was held in the Gardens at Regent's Park on Wednesday, May 17th. The Show was not quite so large as usual, but it was of a bright and diversified character although the weather was showery. The groups of plants, tastefully arranged, made a charming feature, as likewise did the collections of Roses staged by various growers. Azaleas were, as usual at this Show, very fine, and the same may be said of the Fancy Pelargoniums. Begonias and Calceolarias, too, were conspicuously shown, as also were hardy flowers and specimen plants. Appended are the names of the prizewinners in the competitive classes, also the other awards made for the various exhibits.

In the open class for twelve stove and greenhouse plants in flower, Mr. J. F. Mould, Pewsey, Wilts, was first. This exhibitor staged the same plants apparently as were shown by him at Earl's Court a few days previous. They were fine specimens, and reflected credit on the grower. Mr. Mould was also first for six stove and greenhouse plants in flower, which included a fine *Ixora* *Dixiana*, and other grand examples. Mr. Henry James, Castle Nursery, West Norwood, secured the second prize, showing smaller but well flowered plants. Mr. A. Offer, Handcross Park, Crawley, was first in the amateurs' class for six stove and greenhouse plants, staging *Hedera* *fuchsoides*, *Anthurium* *Schertzerianum*, *Statice* *profusa*, *Azalea* *Duc de Nassau*, *Erica* *Cavendishi*, and *Aphelexis* *macrantha* *purpurea* in splendid condition. Mr. Offer was also first in the open class for six Cape Heaths with well grown plants, Mr. J. F. Mould being second.

Greenhouse Azaleas were very fine, the plants being profusely flowered. Mr. R. Scott, gardener to Miss Foster, The Holmes, Regent's Park, was first in the amateurs' class for six plants, showing well-trained specimens. The best were *Phœbus*, *Duchess A. de Nassau*, *Ceres*, and *Reinc de Pays Bas*, all in first-rate condition. Mr. A. Offer was second with larger plants, but not so densely flowered. Mr. H. Eason, gardener to B. Noakes, Esq., Hope Cottage, Highgate, secured the first prize for six greenhouse Azaleas in smaller pots. These plants were also covered with bloom. Mr. C. Turner, Royal Nursery, Slough, was placed first for twelve greenhouse Azaleas in the open class, staging neat and well-flowered specimens. Mr. Turner was also first for six Azaleas, these plants being very fine, especially *Roi d'Hollande*, *Etendard de Flandres*, and *Duc de Nassau*.

Mr. Henry James was first for six fine-foliage plants, which included *Crotons*, *Dasyliion* *acrotichum*, and *Palms*. Mr. Offer was first in the amateurs' class for six foliage plants, staging remarkably well-grown specimens of *Crotons* *princeps*, *Queen Victoria*, *Cycas* *revoluta*, *Kentia* *Baltimoreana*, *Pritchardia* *pacifica*, and *Encephalartos* *Altensteini*. The same exhibitor was also first for six variegated-leaved plants. Mr. Henry James was second in this class. Mr. Offer likewise secured the first prize for six large specimen Ferns, showing grand plants.

Messrs. W. Paul & Sons, Waltham Cross, were awarded first prize for nine specimen Roses in pots. These were grand plants, and included *Charles Lawson*, *Celine Forester*, *Juno*, *Catherine Soupert*, and *Violette* *Buyer*. For a collection of Roses Mr. C. Turner, Slough, was first with smaller but grandly flowered plants. Messrs. Paul & Sons, Chessington, were second with a collection of fine specimens. Messrs. W. Paul & Sons sent a dozen boxes of cut Roses, fresh and fragrant, and for which a silver medal was recommended. Mr. G. Mount, Canterbury, also had some boxes of cut Roses, the best of which were *Ulrich Brunner*, *Catherine Mermet*, and *La France* (silver medal).

Messrs. J. Laing & Sons, Forest Hill, S.E., were adjudged first prize for a group of *Caladiums*, the plants being fresh and well coloured. The best varieties were *Salvator Rosa*, *Leopold Robert*, *Clio*, *Triomphe de l'Exposition*, and *Candidum*. Messrs. Laing & Sons also secured the first prize for twelve Tuberous Begonias. The best of these were *Earl of Craven*, *Lady Brooke* (certificates), *Mrs. Laing*, and *Stanstead Gem*. Mr. T. S. Ware, Tottenham, was second, showing good plants. Mr. C. Turner was first with six Pelargoniums in two classes. The plants were well flowered, and the best varieties were *Spotted Beauty*, *The Czar*, *Gold Mine*, and *Maggie*. Mr. H. Eason was awarded first prize for twenty-four *Gloxinias*. Mr. T. S. Ware was first with a collection of hardy herbaceous plants, which included *Pyrethrums* in variety, *Inula* *grandiflora*, and hardy *Cypripediums*. Messrs. G. Paul & Sons were second. Mr. Henry James was first for twelve Orchids, which included some well-grown plants.

Miscellaneous exhibits were numerous. Mr. H. J. Jones, Hither Green, Lewisham, sent a grand group of Show and Fancy Pelargoniums in flower, for which a silver medal was recommended. The same exhibitor showed plants of Ivy-leaved Pelargonium "*Ryecroft Surprise*," and these well merited the certificate awarded. Messrs. J. Carter and Co., High Holborn, sent a group of *Mimulus* in bloom, which included a fine variety named *Gloriosa*. A certificate was awarded for this variety, and a bronze medal was adjudged for the whole exhibit. Messrs. Carter & Co. also staged a group of *Petunias* in pots (silver medal), and a certificate was awarded for *Petunia* *Pallas*, a pretty variety. Messrs. J. Laing & Sons had a small collection of rare and new plants, amongst which were *Croton* *Golden Ring*, *Dracæna* *indivisa* *variegata*, *Coleus* *Stanstead Beauty*, and the seldom-seen *Fuchsia* *triphylla*. Messrs. Laing & Sons also had a splendid group of flowering and foliage plants, for which a silver-gilt medal was recommended. This contribution was tastefully arranged, and comprised, amongst other plants, Orchids, *Palms*, *Caladiums*, *Cannas*, *Gloxinias*, and Ferns.

Mr. C. Turner had a small group of *Souvenir de la Malmaison* Carnations and Turner's *Crimson Rambler* Rose (large bronze medal). Messrs. Barr & Son sent a large collection of hardy plants and cut flowers, which formed quite a feature in the Show (small silver medal); and Mr. J. R. Box, Croydon, had a group of Tuberous Begonias, for which a silver medal was recommended. Certificates were awarded for Begonias *Hon. Sidney Herbert*, *Lady Beatrice Herbert*, and *Miss Jenkins*. Mr. Anthony Waterer, Knap Hill, sent a collection of cut Azaleas (large bronze medal); and Messrs. J. Peed & Sons, Roupell Park, had a well-arranged group of miscellaneous plants (small silver-gilt medal). Messrs. G. Paul & Son sent some single Roses and *Cannas*, and Mr. C. Turner a basket of *Rosy Gem* Pelargonium, a charming variety. A certificate was awarded for the last named exhibit. Mr. T. S. Ware had blooms and plants of *Pride of Britain* Carnation, and Messrs. J. Veitch and Sons a collection of *Streptocarpus*, *Rhododendrons*, *Gloxinias*, and *Phyllocactus*. Certificates were awarded for *Phyllocactus* *Niobe*, *Streptocarpus* (for strain), *Rhododendron* *Ceres*, *R. Primrose*, *R. balsaminæ-florum* "*Rajah*," (very fine), and *Gloxinia* *Orion*. Mr. T. J. Seidel, Dresden, secured a certificate for *Rhododendron* *Helene Schiffner*, a pure white variety.

Messrs. Sutton & Sons, Reading, sent a large collection of herbaceous Calceolarias, for which a small silver-gilt medal was recommended. The flowers were varied in colour, and this contribution made a fine display. Mr. Perry, gardener to J. C. Tasker, Esq., Middleton Hall, Brentwood, sent *Canna* blooms (bronze medal); and Messrs. W. Balchin & Sons, Hassocks, a small group of *Leschenaultia* *biloba* *major*, the pretty blue flowers of which were greatly admired.

As usual the exhibits were admirably arranged, the groups of

miscellaneous plants on sloping banks making a charming display. Blended with these were the collections of flowering and foliage plants, amongst which the Roses and Pelargoniums, as already remarked, stood out conspicuously. The customary exhibits in the corridor were, however, absent this year, although apart from this there were plenty to interest the visitors. It rained heavily at intervals during the day, which to a certain extent marred the pleasures usually derived from a fine Show.

#### HARDY FRUIT GARDEN.

**Syringing and Watering Wall Trees.**—Healthy growth can only be secured by constant attention to keeping the foliage clean. Against warm dry walls the aridity of the atmosphere is such during the present sunny weather that insects soon find the conditions most suitable for their increase. If not early attacked with a view to dislodge them they not only usurp young stems and leaves as feeding ground, but form protective coverings to screen themselves from view. This is especially the case with aphides, which curl and pull down the edges of the leaves at the leading points of shoots in such an effective manner that it is difficult for ordinary syringing to reach the crowded colonies thus established. In such cases dipping the infested points in an approved insecticide should precede general syringing. Towards the close of mild warm days is the best time to syringe, either to cleanse the trees from dust or as a preventive of insects, also when applying insecticides. When cold cutting winds prevail syringing as a rule is not beneficial, and should be discontinued. In order to cope successfully against insects and promote healthful growth the state of all fruit borders must be fully ascertained, and moisture if needed afforded to the lowest roots, afterwards mulching the surface with manure to conserve it.

**Extirpating Insects.**—At the present time, owing to the continued dry weather, this is a very needful and important operation. Green or black aphides infest the young shoots of Peaches, Nectarines, Cherries, Plums, Gooseberries, and Currants on walls. If not destroyed they soon arrest as well as cripple growth. Red spider assails both sides of the leaves of Apple trees, also Peaches, while Gooseberries are attacked by the larvæ not only of the Gooseberry and Currant sawfly but of the magpie moth.

**Remedies.**—*Tobacco Powder.*—Slight effects of aphides may often be checked by dredging the infested shoots when damp or wet with tobacco powder, but when the shoots attacked are numerous this method is too tedious.

*Softsoap and Petroleum Solution.*—A solution of softsoap and petroleum made in the following manner will soon exterminate aphides, red spider, Gooseberry and Currant sawfly, and the caterpillars of the magpie and winter moth. Boil 1 lb. of softsoap in half a gallon of water, and when thoroughly dissolved add half a pint of petroleum, allowing the whole to gently boil or simmer for fifteen minutes, by which time, if kept thoroughly stirred, the ingredients will be well mixed together. This mixture is too strong to be used alone. When cool place it in bottles, and a handy insecticide will be ready for mixing with water at the rate of 1 pint to 4 gallons of water. Keep the mixture well stirred and apply with the aid of a spray distributor, by which the solution can be distributed equally and without waste over every portion of infested trees.

*Paris Green.*—This compound, though poisonous and requiring great care in using, is nevertheless one of the finest remedies known for destroying the small but destructive larvæ of the winter codlin, lackey, magpie, and umber moths, which annually work havoc with the young foliage, the flowers, and often the fruit of Apples, Pears, and Plums. During the blossoming period it is unsafe to apply Paris green on account of the bees which, visiting the flowers, perform substantial service in aiding fertilisation. Now, however, that the flowers have decayed, and attacks of the larvæ are imminent, spraying once a fortnight for some weeks with Paris green will prove a most effectual remedy. To apply it so that it acts destructively to caterpillars or other pests it must be distributed in a fine mist-like spray, both on the under and upper surfaces of the leaves where it is deposited as a thin film or sediment. Through this the young caterpillars have to pierce to find the juicy food they seek, but in doing so they imbibe the poison which quickly kills them. The proportions of Paris green and water are 1 oz. to 20 gallons of water. This is safe for tender foliage. Paris green is obtainable both as powder and paste; the latter is the safest and best because it is more easily mixed with water. The best instruments for delivering the mixtures are either a knapsack pump, a spraying machine, or a spray distributor.

**Destroying Mildew.**—Very frequently mildew attacks the young shoots of Apples, Peaches, and Nectarines. It is chiefly induced to appear when the trees are growing in poor, dry, and exhausted soil. In that case little can be done to exterminate it wholly merely by dressing the infested shoots with insecticides. In addition to applying these,

lifting and replanting trees in the autumn in some cases acts beneficially. This method, however, can only be adopted with small and moderate sized trees; those of larger size and long established must be treated to plenty of moisture with clear water, then enrich the soil with liquid manure. The evil of mildew will thus be struck at its foundation. For an insecticide or fungicide that will rid the shoots of mildew after a few applications try a solution of 2 ozs. of softsoap in a gallon of water, mixing into a paste 2 ozs. of sulphur, adding that, well mixing, and syringe the trees. Another good remedy for mildew is sulphide of potassium, half an ounce to a gallon of water. Dusting the affected parts with dry sulphur is also effectual, first wetting the shoots or foliage to cause the sulphur to adhere. In a day or two wash it off again with the syringe, repeating if necessary.

**Blistered Leaves.**—Though not so common as usual in cold spring seasons, any leaves that may be found upon trees curled and malformed in appearance should be picked off and burnt. They are chiefly caused by sudden changes in the temperature, exposure to cold, dry cutting east winds, and a more or less inactive condition of the roots.

#### FRUIT FORCING.

**Pines.**—The sunshine has helped Pine plants to make a sturdy growth never perhaps before seen in these at this time of year. Such conditions should be fully utilised, as under them the growth in the plants may be advanced more expeditiously and with safety, provided proper attention be given to the ventilation, which in sunny weather should be attended to early in the morning. A genial condition of the atmosphere must, however, be maintained by damping all available surfaces about the houses whenever they become dry. This is especially necessary just before closing time, which should be sufficiently early in the afternoon to keep the temperature at 85° to 90° for a considerable time afterwards. During dry weather syringing will be required daily, regulating it by the condition of the weather, house, and plants. The best criterion in the case of the plants is the axils of the leaves, which during the growing season should never be allowed to become quite dry, because many feeding roots exist round the stems of Pine plants which only derive support from the water in the axils of the leaves. Care must be taken at this season not to allow any plant to suffer from dryness, but afford an adequate supply of water, and in all cases with some stimulant such as guano, 1 lb. to 20 gallons of water being a proper and safe liquid, always applying it at the same temperature as that of the bed in which the pots are plunged.

The requisite attention must be given to shading; the thinner the material is for the purpose the better, as only enough shade is needed to prevent the sun scorching the leaves or fruit. Fire heat should be dispensed with as much as possible, but it will still be necessary in the succession as well as the fruiting houses as the nights are still cold. Remove all surplus suckers, leaving one or two on each plant for stock, they being best screwed clean out of their sockets with a pair of long handled tongs. Maintain a temperature of 70° to 75° by artificial means in the fruiting department, and close the house at 90°. Recently potted plants should have a liberal supply of bottom heat: 90° to 95° at the base of the pots will induce the roots to take hold of the soil quickly, and when they reach the sides 80° to 85° will be safer.

**Figs.**—*Earliest Forced Trees in Pots.*—After the first crop is cleared from the trees recourse must be had to syringing twice a day, also watering copiously at the roots with guano or other form of liquid manure. This will enable the trees to make a more vigorous growth, and it is essential that the second growth be well nourished and not burdened with fruit. If the second crop fruits show very abundantly they must be thinned, leaving those at the base of the current year's growth for the crop, and the trees must not be overburdened. Trees ripening their fruit should have lessened supplies of water at the roots, but still afford sufficient to keep the foliage in good health, and discontinue syringing the trees. A circulation of warm air is necessary for the colouring process, leaving the top ventilators open a little at night, the highest coloured fruit being the best flavoured.

*Planted-out Trees.*—The first crop of Figs on the early started trees are now giving indications of ripening, and until it is perfected a little ventilation should be allowed constantly at the top of the house, and whenever the weather is favourable a free circulation of warm rather dry air must be afforded. Cease syringing the trees directly the fruit commences to ripen, and avoid a superabundance of moisture about the house, but moderate moisture is necessary for the health of the foliage. If a good watering is given at that time, and the surface is mulched, it will lessen the need of water during the ripening process, but trees with only limited space for the roots will need occasional supplies, and none must be neglected if necessity arise for its application. Trees swelling their fruit will require attention in stopping the young shoots at the fifth or sixth leaf, and thinning the strong growing shoots to admit light and air to the fruit and wood. Attend to syringing the trees daily, and water abundantly at the roots as often as required, employing weak liquid manure, especially where the borders are small.

*Unheated Houses.*—The trees are showing good crops, and will, with favourable weather, afford an acceptable supply of fruit in August and September. The roots being confined to narrow and well drained borders inside the house, they will require copious supplies of water, and the trees will need syringing twice a day in fine weather. In cloudy weather the afternoon syringing may be dispensed with, and in bright it may be performed early, with all the solar heat that can be shut in to insure the proper drying of the foliage before nightfall. The young

growths should be trained a good distance apart so as to admit light and air freely to the wood for insuring its ripening well. Avoid close stopping, as the results are the production of a number of late growths which do not get properly matured before the leaves fall. The best course is to secure firm, short-jointed wood. Allow the points of the shoots to grow up to the glass, and they will then form abundance of embryo Figs ready for swelling in the spring.

**Peaches and Nectarines.**—*Trees Started at the New Year.*—When the fruit has stoned the trees may be subjected to a higher temperature, but until that is completed they should not be kept in a higher temperature than 60° to 65° by artificial means, commencing to ventilate at 65°, and not allowing 70° to be exceeded without a free circulation of air. Secure the shoots as they advance in growth, leaving plenty of room in the ligatures for the shoots to swell properly, and remove superfluous growths, retaining no more than can have full exposure to light and air. If the shoots are crowded, thin them gradually as soon as the stoning is completed. Do not overburden the trees, but leave one fruit to each square foot of surface covered by them, vigorous trees having the fruit left a little closer. Maintain adequate moisture in the house after stoning, water the inside borders copiously, and mulch the surface with about an inch thickness of partially spent short manure. Outside borders must also be properly attended to in watering and mulching.

If it is desired to accelerate the ripening the night temperature may be maintained at 65° to 70°, 70° to 75° by day artificially, and 80° to 85° from sun heat, closing early so as to increase to 90° or 95°. In this high and moist atmosphere Peaches swell to a great size after stoning. With due precaution taken in having the fruit well exposed, raised with its apex to the light, it is very imposing in appearance, but scarcely so inviting or so well flavoured as that ripened more gradually in less heat and moisture, and with freer ventilation. Unless, therefore, the fruit is required to be pushed the ripening should be effected in a night temperature of 60° to 65°, 65° by day artificially in dull weather, and 75° with sun heat, closing at the latter with plenty of moisture in the house. Ventilate freely when the fruit is ripening, admitting a little air constantly.

*Trees Started in February.*—The fruit is now stoning, and the number must be reduced, leaving two on strong shoots, but one only on weakly growths. Retain fruits in all instances best situated for exposure to light and air. Thin the shoots where overcrowded, and remember that the more light and air the fruit is subjected to from the commencement the better will it be in colour and flavour when ripe. The temperature may be kept at 55° to 60° at night, 60° to 65° by day artificially, ventilating at 65°, fully at 70° to 75°, and closing at the latter with plenty of moisture. Assist weakly and full-cropped trees with liquid manure, but keep it from trees that are very vigorous, as it tends to gross growth, and may prove fatal to the stoning. Syringe the trees twice a day, and spare no effort to maintain the foliage in a clean, healthy condition.

*Trees Started in March.*—The fruit now swelling freely must be well thinned, but gradually, leaving two or three of the best placed on strong shoots, and proportionately less on weaker growths. Supply liquid manure to weakly trees, but top-dress vigorous with phosphatic manure, say a sprinkling of dissolved bones, 2 ozs. per square yard, occasionally, as they being more prone to cast the fruit in stoning should have water only. Remove all superfluous shoots, tying and training the remaining growths to the trellis as they advance.

*Late Houses.*—It can now be seen which fruits have most promise, therefore the thinning should be carried out promptly, leaving a few more only than will be required for the crop to allow for casualties. Examine the inside borders at least once a week, giving thorough supplies when necessary, and syringe the trees twice a day, except when the nights are likely to be cold. This more particularly applies to unheated houses, in which the syringing should be practised early in the afternoon or be omitted, for it is essential that the foliage become dry before night. Early closing may also be practised with a view to husband the sun heat.

**Strawberries in Pots.**—The latest plants will now be commencing to swell the fruit, and as the stems are usually long the berries should be supported clear of the pots with forked sticks, pointed at the stem end and pushed into the soil, the stem of the truss resting in the fork or a little below the fruit. Thin the flowers and the fruits. The centre fruit is always the largest, and to encourage these and others early thinning must be practised. Grand fruits are obtained in this way, seven fruits this year of Auguste Nicaise only being required to bring up a pound weight in their favour. Marguerite produces enormous fruit, five to a pound having been produced, but it spots seriously through its tender skin, and President also is very liable to damp and mould when ripening. The plants should have frequent supplies of liquid manure for swelling their fruit, giving it from the time the fruit commences to swell freely until it changes colour for ripening, when clear water, and not too much of it, only the plants must not flag, will be more suitable. When ripening the atmosphere must be kept rather drier and cooler than when the fruit is swelling, and it will then be less liable to spotting, the flavour be higher, and the aroma more pronounced.

#### THE FLOWER GARDEN.

**Commencement of Bedding Out.**—The summer-like weather has materially shortened the duration of various spring flowering occupants of the beds and borders, and will also have the effect of hastening the

refilling of these latter with the more tender plants prepared for them. As far as the state of the ground is concerned, that at the present time is warmer and in a better condition for the reception of tender plants than is often the case by the middle of June, and all we have to fear are cold frosty nights. These may not be noticed this season, but when the change comes the chances are frost, and perhaps hailstorms, will follow in the wake of heavy rain. There ought, therefore, to be no risks run, especially where there are few or no reserve plants to make good any losses. It is always a relief to get the bulk of the bedding plants, more especially those in pots, into their flowering quarters, and there is no apparent reason why the start should not be made at once if precautions are taken for protecting them if needed with evergreen branches, blinds, or mats. With a good supply of water near at hand the mistake is often made of using this far too freely. Enough should certainly be given to prevent the plants flagging badly, but the greater part of them, and Zonal Pelargoniums in particular, take more quickly to their fresh quarters, and are less likely to be injured by frosts when kept a little on the dry side at the roots for the first fortnight.

**Tuberous Begonias.**—If these are planted out early, provision ought certainly to be made for protecting them during cold nights, and a light shading during clear hot days would also prove beneficial. These plants are not suitable for hot and dry positions, but thrive admirably in the more low-lying beds; or say, where Zonal Pelargoniums usually grow too strongly and flower indifferently. The most exposed beds can, however, be made suitable for them. What they require is a fairly deep, well worked root run, plenty of decayed manure being forked in. Failing the latter use leaf soil. In addition they will also require to be freely mulched, this being done directly after planting. Old Mushroom bed refuse, leaf soil, and cocoa-nut fibre refuse are all variously used as a mulch, and answer well. Never crowd Tuberous Begonias, the best effect being produced by keeping the plants just clear of each other, the handsome foliage then showing off the fine flowers to advantage. Strong plants from tubers raised last season will give the best results, and these may be not less than 15 inches apart each way, while the strongest of those raised this season, and which can be moved out of boxes or frames with a good ball of soil about the roots, may be arranged 12 inches apart. A pretty effect is produced and an economy of plants be effected by disposing the Begonias another 3 inches farther apart, and carpeting over the intervening spaces with either Mesembryanthemum cordifolium variegatum or Sedum glaucum, these cool trailing plants also obviating the necessity for mulching the beds. Dwarf Lobelias are suitable for mixing among or edging Begonias, while if really imposing effects are desired fill large beds principally with Begonias, dotting Cannas, variegated Maize, Acacia lophantha, standard Fuchsias, Palms, Dracaenas, and such like thinly among them. The erect flowering varieties are the best for bedding out; while those with drooping flowers are very effective when fringing raised beds and in vases, always providing they are kept well supplied with moisture.

**Other Moisture-loving Plants.**—Violas are next to useless for hot and dry positions. They ought to be put out early, being given the benefit also of a well-manured root run. If variegated Zonal Pelargoniums of any kind are dotted freely among Violas the effect is pleasing, and there will be no blanks very observable even if the latter do fail in August. Shrubby Calceolarias are also unsuitable for hot and dry positions, and should have the sites well prepared for them. See that they are in a thoroughly moist state at the roots when moved, and they must not flag through want of water at any time. Polemonium coeruleum variegatum is quite a moisture-loving plant, and very effective too when properly treated. Verbenas, to succeed well, should have deeply dug, well manured sites, a mulch of some kind not being wasted on them. If clean, healthy young plants are planted on this well prepared ground they will flower grandly and attract, because not often seen in good condition. Fuchsias will not long grow and flower freely unless given the benefit of a rich root run and plenty of moisture. Dahlias also like plenty of manure and moisture.

**Plants for Drier Sites.**—Zonal Pelargoniums are the most effective in fairly good soil and open positions. Heliotropes, Ageratums, Iresines, Coleuses, Golden Pyrethrum, Lobelias, and the various annuals raised under glass, all thrive well in a medium soil, and the bulk of them will stand drought fairly well after they are once well established. Petunias are suitable for quite the driest beds, and Marguerites may be associated with them advantageously. Dwarf Nasturtiums, if grown on rather poor soil and given good room, are remarkably showy, and stand both wet and dry weather well. If the beds are in a very dry state when they are to be filled give them a good watering a few hours in advance of planting, and the work can then be done easily and properly.

**Late Raised Plants.**—When boxes or pots are scarce or space limited many of the late raised plants are frequently kept very close together much longer than is good for them, and unless something is done to obviate this they plant out badly. Pots and boxes being liberated owing to the harder or earlier raised plants being put out in the beds, these might well be refilled with those raised later. Especially ought Iresines and Coleuses, now crowded in cutting pots or pans, to be placed singly or in pairs in small pots, and if kept in gentle heat till the end of the first week in June, they will have grown considerably and be well rooted. Being duly hardened off they will be ready for the spaces left for them in another week, the extra trouble being amply compensated for almost from the first. It is not yet too late to root more tops of Iresines, Coleuses, and Alternantheras, and this should be done if more plants are wanted.

# THE BEE-KEEPER.

## APIARIAN NOTES.

### HINTS TO BEGINNERS.

At this season of the year a prime swarm contains the old queen, and is likely to swarm again in about six weeks hence if the weather is favourable. This second issue is known amongst bee-keepers as a "virgin" swarm, and is as likely as not to have a virgin queen, but it will be as well for the future if the novice regard it as the old one; then one or more after swarms may be expected, and these should be kept as stocks. If "C. W." (page 385) puts one of these in the frame hive it will give him a fair start with every chance of success another year. Should the hive not swarm by the end of June he should drive the bees, depose the old queen, and introduce a young fertilised one.

Whenever the honey is plentiful in the straw hive and the bees working, put on a small wooden super about 8 inches square by 4 inches deep. These supers ought to have bars, so that should a good season occur, they may be storified. An adapting board may be used between the hive and super, with narrow slits at the extreme sides. This prevents the colouring of the comb, also to a great extent the queen ascending, and prevents the bees fastening their combs to the crown of the hive. If the hive is dome-shaped support the adapting board, so that it lies level and solid. A piece of clay is handy for that purpose. Assuming the hive swarms, drive the bees three weeks afterwards, utilise the honey, and feed with syrup—the best sugar, dissolved with equal weight of soft water, stirred while on the fire, and boiled a minute, or even less. The most practical and reliable paper on bees is the *Journal of Horticulture*, and questions are not answered by theorists, but successful bee-keepers.

### THE MOST PRODUCTIVE HONEY BEES.

Perhaps the most satisfactory pure bred bees are the Carniolans. They are prolific, good workers, and honey gatherers, make beautiful white comb, and are very mild tempered. Unhappily care has not been taken to preserve the race, and it appears difficult to get the pure breed. *Cross-bred Punics* have, on the whole, surpassed all the other varieties—i.e., whether they be Carniolan queens and Punic drones, or *vice versa*. The pure bred Punics had not a fair trial by myself last year, but in 1891 the finest supers of Heather honey were from pure Punic bees. When intending bee-keepers cannot obtain a particular race of bees they must take the best they can find in the neighbourhood. This is a sensible plan for beginners, and they should give no heed to those who allege that the old British bee is still to be had in its pure state. It suits interested people to advocate them, but they are extinct in this country.

### THE GREATEST HONEY YIELDS.

These have been afforded by crosses on the non-swarming storifying system, and in short seasons on the old two queens in one hive system. In 1860-61-62, when in many places there were no honey, I saw huge supers from 45 to 50 lbs. in weight. But with all kinds of hives the results are of necessity influenced by the season and flowers.

In the spring, if I remember rightly, of 1878, old stocks swarmed three times, which increased each stock to four during the month of May. By June, and to the middle of July, the old stock again swarmed twice, and so did the prime swarm as well as the first after swarm, raising the number to ten; the season was prolonged and fine. Seven of the number were put down and three of them kept as stocks; the former weighed from 75 lbs. to 115 lbs. They were in straw hives, the tare of each being about 12 lbs., so that the nett contents of the seven hives from the one stock in the same year amounted to 665 lbs. of honey. This stock was situated on the Duke of Hamilton's estate, about three miles from where I live. At Arran in 1863 there was a similar case of increase and yield of honey, which sprung from a stock of crossed Italians. A moderate increase of stocks will be found one year with another to be the safest course to pursue.

### THE BEST HIVE.

The Lanarkshire storifying hive now being adopted in some form or other in this country and America is, I am able to say, after upwards of forty years' experience with it and others, the cheapest and best hive. It is easily made by amateurs, and, moreover, is the only safe hive for taking to the Heather and for wintering bees. I will endeavour to advise beginners, but they must remember that their own judgment must be exercised to the fullest extent. While

they are getting advice a little thing may compel them to depart from a prescribed course, as it is impossible to anticipate all the movements of bees.

### EARLY SWARMING AND HONEY.

If swarming began in England on the 21st April Scotland was not far behind. From previous reports I believe some swarms would be as early on some parts on the Clyde side. On the first day of May there were swarms at Brownlee, Barrhead, Blantyre, and Bowling. At Crossford and other places in Lanarkshire large quantities of honey of the first quality were taken in April.—A LANARKSHIRE BEE-KEEPER.

••All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Fungus in Mushroom Bed (T. B.).**—The name of the fungus producing Sclerotia in Mushroom bed, mentioned on page 385 last week, is *Xylaria pedunculata*.—W. G. SMITH.

**Hardy Azalea (C. H.).**—The flowers were quite withered on arrival. The colour appears to be darker than that of Anthony Koster. Your shrubs must have been highly effective.

**Proliferous Calceolarias (J. Haffenden).**—We have seen many similar examples of what appears to be two flowers on one stem, but there are really two stems or pedicels united, and the furrow is quite apparent. It is a case of fasciation.

**Beetle and Plants (J. D., Duffryn).**—The beetle is evidently the common cockchafer (*Melolontha vulgaris*), which has of late years seemed to be less abundant than usual. Neither moth nor fly was discoverable in the mixture, but the former is probably the pea-green Oak moth (*Tortrix viridare*); and the transparent winged fly referred to may be some species of *Ephemera* or May fly. This is, however, only a supposition. The flower bud and small leaf are wholly insufficient for identification. If further specimens are sent they must be larger, more advanced, and not enclosed in a package with insects.

**Liquid Manure for Strawberries (L. F.).**—There is no better liquid manure for Strawberries than the drainage from manure heaps or sewage, but when these are not obtainable guano water may be used, and has often been applied with great benefit. Half an ounce dissolved in a gallon of water is sufficient for plants in pots, but twice that quantity may be applied safely to established plants that need extra support in the open air. It should not be poured on the fruit or leaves, only on the soil, copiously, and if this can be mulched afterwards for the retention of the moisture it will be an advantage. It is an excellent plan to give liquid manure as soon as the fruit is set, then cover the ground with straw or other suitable material for keeping the fruit clean and preventing the evaporation of moisture from the earth. The use of liquid manure should be discontinued when the fruits commence colouring.

**Introduction of the Moss Rose (Amateur Rosarian).**—You ask for information regarding the introduction of the Moss Rose. We have referred to many old authorities, and the results of our search are that Parkinson in his "Paradisus," published in 1629, Rea in his "Flora," published in 1665, and Bauhin in his "Pinax," published in 1671, enumerate many Roses, but the Moss is not among them. It was introduced or raised in Holland probably at the close of the seventeenth century, for Dr. Martyn, in his edition of Miller's "Gardeners' Dictionary," says it is in Furber's catalogue in 1724. We have seen a copy dated 1727; it is entitled "Catalogue of English and Foreign Trees Collected, Increased, and Sold by Robert Furber at his Nursery over-against the Park-Gate at Kensington, near London." Faulkner in his "History of Fulham" says that Mr. Rench was the first to introduce the Moss Rose into this country, the original plant of which is supposed to have been brought from Holland. Rench lived at South Field Farm, near Parson's Green, a farm possessed by his family for two centuries. He was buried in Fulham Churchyard, where there is this inscription

## ORGANISATIONS.

ORGANISATION is the order of the day, isolated action, broadly speaking, fast becoming obsolete. This applies to industries and "interests" of various kinds with which many people are connected. Isolated individual action there must always be on the part of students and specialists who think and work out problems that lead to inventions of various kinds, some fanciful, others having important bearings in the scientific and commercial world. It is feared by some able men that organisation is inimical to individualism—that it tends, to so say, to produce a machine-like action in humanity, and an uniformity in modes of thought and intellectuality. But may not the reverse be the case? Is it not the fact that some of our greatest men have mixed much with the multitude in their respective circles? and may they not thereby have received new thoughts and been impelled to higher aspirations and greater research into subjects which have become indissolubly connected with their names? Be that as it may, organisations of individuals for the furtherance of legitimate objects have been of enormous, indeed incalculable, benefit to the nation. That mistakes are made by associations, unions, leagues, or guilds, call them what we may, goes without saying. They are incidents in the lives of men whether they act in an individual or corporate capacity, and the objects in view are then retarded, loss incurred, and it may be suffering endured. These are the penalties of errors in judgment, and their occurrence should, and in the long run does, lead to the exercise of greater prudence on the part of the public as a whole, for sharpers there will ever be so long as there are dupes, as one cannot exist without the other, and so far combinations do not seem to have materially reduced either of those distinct "individualities."

Organisations in the form of societies established for mental or moral improvement and professional advancement are altogether worthy when worthily conducted; while clubs for wholesome recreation and physical exercise, in which the different classes of society meet in friendly association, have a decidedly beneficial tendency in the cultivation of social amenities, which play an important part in making life agreeable, and moulding the habits of the community. We are not led into this strain of thought by Messrs. Wood & Son's great idea on page 390 last week. In respect to that we adopt a waiting policy, with the remark that some such amalgamation as they propose has been satisfactorily effected in some Continental cities; but whether we possess an organisation of horticulturists sufficiently strong and cohesive to form a substantial element for purposes of negotiation is a question for consideration. It was not that proposal, but the *Journal* of the "Kew Guild" that brought the subject of organisation to the fore, and particularly some introductory remarks by Mr. W. Watson, Assistant Curator, in the form of a letter to Mr. W. T. Thiselton-Dyer, Director, asking his sanction of the project, and this gentleman's admirable reply. Mr. Watson writes:

Kew is popularly known as a great botanical institution possessed of a garden wherein is grown the most comprehensive collection of plants ever brought together in any country. Her influence in science and commerce has long been acknowledged as pre-eminent among botanical establishments. Kew is also a great training school for horticulturists, but the important part she plays in horticulture has not hitherto been generally recognised. The

Kew Guild will, we think, go a long way towards showing how much Kew has done and continues to do, in the development of scientific horticulture, not only in the British Empire, but in all the civilised countries in the world. Our *Journal* will reveal the whereabouts and positions of all living Kewites, as far as they can be ascertained. Kew "graduates" are everywhere; as directors, curators, superintendents, head gardeners, as botanists, professors, Fellows of the Royal Society, the Linnean, and other great scientific societies; wherever botany or scientific horticulture is encouraged, there Kewites are sure to be found.

We have made a rough calculation of the number of men now alive who have been employed as gardeners at Kew, and find there are probably about 500. They were all young men when they entered Kew, and it is only natural that whilst here they formed friendships and acquired an interest in and affection for their "high school" which did not die with their departure to other places. The desire to know of the whereabouts and career of their fellow workers whilst at Kew, and to learn something of the way things are done in the Garden now is very general among Old Kewites, and sometimes finds expression in letters of inquiry to present members of the staff, but this is necessarily an unsatisfactory method. Our Guild and *Journal* will remove all difficulties of this kind. We shall now be able to shake hands with each other no matter by what distance of time or space we are separated.

The Kew Guild is the offspring of the Kew Mutual Improvement Society, which has been in existence some twenty years, and which is devoted to essays and discussions on professional subjects. This Society is now most popular with the garden staff, and is looked upon as being one of the most valuable means of professional improvement. It is at the same time, to all intents and purposes, the "Club" of Kew men. Old Kewites retain an affectionate feeling for "the Mutual," as is abundantly shown in their correspondence; inquiries as to the proceedings and prosperity of the Society being frequent. This desire to keep in touch with each other found expression last year in a resolution to take steps to unite by some means all Kew men, and it was finally decided to form a Guild and publish a *Journal* annually. We hope in time to be in a position to hold an annual meeting, a general muster, a Club day at Kew, or somewhere near. An annual dinner might be arranged at which all the members possible might be present. Any suggestion as to the best means of making our Guild a genuine union of hearts, and as far as possible of hands also, will be most welcome.

To the scheme as above foreshadowed the Director of Kew gave his ready adhesion in a letter to Mr. Watson, which we think is worthy of a wider circulation than it can be expected to have in the first excellent issue of the *Journal* of the "Kew Guild." Mr. Thiselton-Dyer writes:—

I think the idea of the proposed Kew Guild is a very excellent one. Such an organisation cannot but have the effect of consolidating the *esprit de corps* which already exists amongst our young men, and its doing so will, I do not doubt, be of great benefit to the establishment.

It has often struck me that the young men—of whom there is now a not inconsiderable body employed—who come to Kew for a period of advanced training and instruction, enjoy in no small degree much the same advantages as in other classes of the community are afforded by university life. It is generally considered that the most important of these are the formation of character and the reception of those impressions which determine an intelligent interest in, as opposed to a merely mechanical pursuit of, the occupations of life. The age at which young men come to us is about the same as that at which others go to the universities. It is the age when the responsibilities of life begin to emerge above its horizon, and it is the age when, for better or worse, the future career, as far as it depends upon the influences under which a young man is thrown, pretty distinctly shapes itself.

I have always felt that a great responsibility falls upon the staff in doing what can be done to maintain a healthy and somewhat stimulating tone throughout the establishment. As you know we do not "coddle." We treat our young men as "men," and expect them to work out their own salvation. We wish them to be manly, self-respecting, and strenuous. We put, with the aid of the Government, what help we can in their way, and leave them to make an intelligent use of it.

Just as at the universities, one of the great advantages of Kew, as it seems to me, is the association within it of a large body of young men of the same age and with the same pursuits. Such an

association is itself an education and a preparation for the bigger world of life. Rubbing together in the work of the day, in the lecture-room, the reading-room, the Mutual Improvement Society, and the cricket-field, they learn to appreciate and understand those good personal qualities which enable capable men to advance themselves with modesty, and everyone to get through the business of life without undue self-assertion or individual friction. This is the great merit of university training, and something of it I am sure is attained at Kew.

Out of this grows one of the greatest charms of life, the formation of permanent and valuable friendships. But stay at Kew is short, and I have always felt that some organisation such as you propose would serve the double purpose of keeping Kew in touch with the men who have passed through it, and of enabling the men themselves to keep in touch with one another. Sometimes in turning up old files of correspondence I have come across letters from distant parts of the world from men who were once with us. And nothing has encouraged me more as Director than to see the spirit of loyalty, not to say affection, which always animates Kew men towards their *Alma Mater*.

Men go from us to all parts of the Empire, some in official, some in private employ. The maintenance of correspondence with every individual would be impossible. Still, to have a record of their whereabouts, to rescue their names and work from the oblivion which sooner or later falls on everything human, will be of interest to everyone concerned.

After all, it is interest which makes work endurable, and anything which stimulates it in the long run well repays the trouble.

Kew has now completed the first half century of its existence as a national and public institution. It has accomplished work already of which any institution might be proud. Its carries its influence through its men to every part of the world. That it is so strong arises in great measure from the fact that the uniform tradition which has animated every member of the staff from top to bottom is to work self-sacrificingly for Kew rather than for himself. Officials and employes arrive and pass away; the institution remains, and grows in usefulness, in strength, and in beauty. All who have had a hand in the work are content that that should be their "record."

No one will find fault with us for reproducing the above letters, and if any hitherto undiscovered "Kewite" should be reached through our columns, he will, we suspect, hasten to be enrolled a member of the Guild, and recognising the salutary objects in view, we wish the organisation complete success.

## UTILISING SURPLUS FRUIT AND VEGETABLES.

REPORTS concerning the extent of the hardy fruit crops are somewhat conflicting, but there appears to be a great abundance in some localities and a fairly good promise in others, these last being the greatest sufferers by frosts, which were very severe during the flowering period. Seeing what immense additions have of late years been made to the breadths of ground wholly or principally devoted to fruit culture, there is every prospect of the supplies this season being largely in excess of anything yet recorded, and the chances are, therefore, that prices will rule lower than usual. With an increasing demand for good wholesome fruit, and which, as yet, is largely met by importations, it seems a great pity that any should be wasted for want of a little enterprise and skill on the part of those who have so much at stake. That a good market can be found for either first-class fruit preserves, bottled or candied fruits, I have not the shadow of a doubt, yet I advise no one, without any previous experience, to commence utilising their surplus fruit, or any, say, that cannot be profitably sold in a fresh state, to good account on a large scale, or they may get into the Bankruptcy Court before they know what they are about. First gain some practical experience on a small scale, and then launch out deeply and boldly. It is next to useless for persons to expect to be taught delicate manipulative acts from information supplied through the medium of either the press or private correspondence. Many useful hints may be obtained in that way, but it is only by practical experience, gained first on a small scale, that big ventures can be safely piloted to success. Much useful knowledge could be gained by a visit to an Italian warehouse or large grocery store, where all the best samples of preserves and bottled fruits may be seen, and in particular a knowledge of the latest styles, both in the jars and bottles, with the different methods of making these air-tight in vogue. Those who at present only contemplate going to work on a small scale may be content with more homely methods of bottling, stopping, and such like, and they

will then be gaining much useful experience, and be better able to appreciate the more advanced practices of experts.

Judging from inquiries which evidently have reached the Editor of the *Journal of Horticulture*, beginners are somewhat at a loss how to go to work, even on a small scale, and more especially as to the time that the different kinds of fruit and also vegetables require to be subjected to the boiling or steaming process. On page 368 there are several useful hints given as to how to proceed in the work of bottling fruit on a large scale, and these with slight modifications would answer equally well for the modest beginner. Green Gooseberries, ripe Apricots, Cherries, Currants, Green Gages and other Plums, Damsons, Raspberries, Strawberries, Peaches, and small whole and quartered large Pears are all suitable for bottling, for future use in pies and such like, and the method of procedure should be very much the same in every case. I believe some of the larger firms who bottle these very extensively fill with water only, but the old housewife's fashion of surrounding the fruit with clarified syrup is what I would still recommend. This syrup can be prepared as follows:—To every 3 lbs. of loaf sugar add the white of an egg and 1 quart of water, all being whisked together in a stew pan, then set to boil gently for five minutes, a little cold water being added occasionally. After being strained through a cloth it is ready for use. The fruit to be bottled should be quite sound, nearly ripe Plums being preferred to any full ripe or cracked. These, also Apricots and Peaches, must be halved and the stones taken out, while the stalks have to be removed from all. After all have been neatly packed in the usual wide-necked bottles or the more improved jars and bottles alluded to on page 368, filling them to the neck, and then after pouring enough syrup to well cover the fruit they must be corked down tightly. Machines can be had for the latter process, bottles being corked in Messrs. Beach's factory very rapidly with their aid. The next proceeding should be to pack the bottles in either a stock-pot, large kettle, or saucepan deep enough to admit of their standing upright in cold water up to the neck. After packing haybands round them to prevent their knocking against and cracking each other set the pot over a fairly brisk fire. Rather more time is allowed for some fruits than for others. Thus, after the boiling point is reached in the case of Gooseberries, another five minutes gentle simmering is needed; Currants, Raspberries, and Strawberries being allowed ten minutes, Apricots and Cherries twelve minutes, Plums and Damsons, Peaches and Pears one-quarter of an hour, simmering in each case after boiling point is reached; the bottles to remain in the water till nearly cold, and be then duly wiped dry, faulty corks made good, and air be further excluded by means of either a covering of wax or a piece of tinfoil. The glass jars having a neck flange, rubber ring, and screw top are a great improvement on the old bottles, and would doubtless, if advertised, meet with a great sale.

Vegetables, now that the drought has broken up will soon recover their lost ground, and most of the kinds suitable for preserving will doubtless be plentiful enough. French and Runner Beans are always appreciated, and the former, especially, might well be extensively grown, especially for storing. In all probability it would pay well to prepare them largely for winter use, and those who can place a good article on the market would have the monopoly as far as foreign competitors are concerned. A good recipe for preserving them is as follows:—Pick and string any given quantity of young Beans, and throw them into a large untinned copper preserving pan containing boiling water strongly impregnated with salt, cover them with fresh Vine leaves, and set them aside for twenty-four hours. They should then be drained upon a sieve, gathered up in neatly arranged bunches, and packed closely together, in either jars, bottles, or tin boxes, filling up with fresh water slightly flavoured with salt. Cork down, or otherwise make these air-tight, leakages also being remedied, and store in a cool place till wanted for use. Peas and Broad Beans are worthy of being extensively preserved, and for these also I have a recipe that will be hard to surpass. Tins or cans have hitherto been principally used for these, and those who intend trying what they can do in the way of preserving Peas should first obtain a sample tin or can from an Italian warehouse or grocer, and get a local tinman to copy and make the requisite number with their tops ready for soldering down complete. Fill these with fresh, newly shelled Peas; cover with water to which a teaspoonful of salt, or enough to well impregnate it has been added, and then solder or screw down the tops as the case may be. Place them in a stock pot or saucepan, cover with boiling water, and boil them fast for half an hour, and then withdraw. Examine the tins for leakages, solder over, and store in a cool dry cellar. If strong glass bottles or jars can be procured, these, as explained on page 368, are decidedly preferable. Carrots in a young state are largely preserved, and a very tender dish is available accordingly during the winter. These should be closely trimmed lightly scraped, and

dropped into hot water according as they are done. When enough are ready, place them in a stewpan with water sufficient to cover them, adding fresh butter at the rate of 1 oz. to the pound of Carrots, and salt to season. Boil the Carrots in this till half done, arrange them closely in jars or tins, fill with their own liquor, fasten or solder down, boil for half an hour, and store in a cool place.

Mushrooms—"buttons"—can be preserved against the time when fresh ones cannot be had. They must be quite fresh and firm for the purpose, be washed, packed in boxes or jars, and these filled with water, to every quart of which 4 ozs. of butter, 1 oz. of salt, and the juice of three Lemons has been added. After being duly fastened or soldered down they ought to be boiled for a quarter of an hour. If anyone can add to or improve on the foregoing recipes they will confer a great favour on myself and various other readers of this paper.—A MARKET MAN.

### FRITILLARIAS.

THE genus *Fritillaria*, though it contains many plants of little more than botanical interest, is on the whole a very useful one, and is deservedly popular with all lovers of hardy bulbous plants. There are, according to the "Genera Plantarum," upwards of fifty distinct species, some of which have a considerable number of varieties. The genus is pretty widely distributed; the majority of the species are natives of South Europe and Western Asia, a few are found in North-West America, while India and China are also represented. Only one species, *F. meleagris*, the common Snake's Head, is a native of Britain. Naturally, in so large a genus, with such a wide geographical range, there is considerable diversity in form, habit, and colour.

With very few exceptions *Fritillarias* are easily cultivated. Most of the species may be grown in the mixed border. The Crown Imperials (*F. imperialis* and vars.) may also be utilised for shrubbery borders or for naturalisation. The smaller kinds should have a place to themselves in a sunny border in a sheltered position. The more valuable and refractory of the smaller species may be planted out in cold frames. A deep sandy loam is the most suitable soil for all the species, and whatever position be assigned them they should be disturbed as little as possible, as they are very impatient of interference with their roots. They need not be lifted oftener than every three or four years, and they should then be replanted immediately in fresh soil. Autumn is the best time for this operation. The Crown Imperials should be planted at least 4 inches deep, as the stems throw out roots above the bulbs; half this depth will be sufficient for the smaller kinds.

*Fritillarias* may be grown in pots in cold frames if desired for the decoration of the greenhouse in spring; but they will not bear forcing, and do not succeed so well in pots as in the open ground. The only advantage of pot culture is that the plants bloom a little earlier.

Propagation is most readily effected by offsets, which most of the species produce freely if left undisturbed. These may be collected when the old bulbs are lifted, and should be planted in rows in nursery beds until they attain flowering size. Some of the species ripen seeds freely, and these may be sown in pans filled with sandy soil. They must not be shifted during the first year, but may afterwards be planted out. This method is not generally practised, however, as seedlings take from four to six years to reach the flowering stage. The following are some of the most noteworthy species:—

*F. ARMENA*.—This is a dainty little plant about 6 inches in height, with small, campanulate, slightly drooping flowers. There are two forms of this species, one with soft yellow flowers, and the other with brownish-purple flowers. A native of Armenia; introduced in 1878. Flowers in April.

*F. AUREA*.—This species has bright yellow bell-shaped flowers, about 1 inch deep, and is a desirable little species. It is about 6 inches in height. Introduced from Cilicia in 1876.

*F. BREVICAULIS*.—Another dwarf species, seldom attaining a height of 8 inches. The flowers, which are produced singly or in pairs, are of a tawny colour, and are not very large.

*F. DELPHINENSIS*.—A South European species, 6 to 12 inches in height, and is useful for naturalisation. It has purple flowers, spotted with yellow. *F. d. Burnati* is a handsome variety of the above, with large solitary drooping flowers of a brownish-red, chequered with pale green. Introduced in 1879; flowers in March. *F. d. Moggridgei* is also a charming variety, about 1 foot in height, which flowers in August. It was introduced in 1880, and has large solitary flowers of a bright yellow spotted with brown.

*F. IMPERIALIS*.—The Crown Imperial is the giant of the genus, and is too well known to require a detailed description here. It is one of the very oldest of our garden plants, having been intro-

duced from Persia in 1596. There are several varieties of this species differing principally in colour. In the variety *aurea marginata* every leaf is margined with a broad yellow band. The flowers of this species have unfortunately a somewhat disagreeable odour.

*F. LATIFOLIA*.—This species is admirably adapted for naturalisation, as it will thrive in any open situation. It is a native of the Caucasus, and was introduced as long ago as 1604. It is about 1 foot in height, and the large flowers are pendulous. April and May is the flowering season. There are numerous varieties varying in colour from yellow to black.

*F. MELEAGRIS*.—This is a native species, and is the most useful member of the genus, as it will thrive in almost any

FIG. 74.—FRITILLARIA TULIPIFOLIA.

situation, and is also serviceable for pot culture. There are innumerable varieties of this species in various shades of colour, and all more or less chequered, as in the type. There is also a variety with double flowers, but this is still a rare plant.

*F. PALLIDIFLORA*.—A Siberian species; about 1 foot in height. It is very distinct; the yellow flowers, which are beautifully chequered internally, being borne in terminal clusters. Introduced in 1880.

*F. PUDICA*.—This dwarf Californian species is one of the very best. It does not, however, possess a strong constitution, and many have failed to grow it satisfactorily for any length of time. It is about 8 inches in height, with an upright leafy stem and large golden yellow flowers. It blooms in May.

*F. RECURVA*.—The showiest of the *Fritillarias*, but, like the preceding species, it is not quite so easily grown as some of the others. It seems to be affected by local influences, as some growers have entirely failed with it while others declare it to be as easily

managed as any. It certainly is not a robust plant, and it requires protection during winter, but it will well repay a little extra care. The flowers are large, and have the appearance of Lilies owing to the perianth segments being considerably recurved; they are bright scarlet freely spotted with yellow, especially internally, and are borne two to eight in a terminal raceme. It is a Californian species, grows about 2 feet in height, and flowers in May.

*F. TULIPIFOLIA*.—This is a dwarf Caucasian species, remarkable chiefly for the peculiar glaucous blue colour of its flowers externally; internally they are brownish red. It is a variable species as regards size. Introduced in 1872. The illustration (fig. 74) represents it.

A new species from Smyrna has been named *F. Whittali*. In size and general appearance it resembles *F. meleagris*, except that the perianth segments are slightly recurved and not incurved as in the latter species. The flowers are of a greenish colour chequered with brown.—A. B.

## THE INFLUENCE OF A GARDEN.

MUCH that is elevating might be written upon the soothing peacefulness of a garden, and the contrast its calming influence presents to the nervous strain and peace-shattering intensity of city life. It is difficult indeed for a jaded denizen of the modern Babylon, unless he is a happy inhabitant of its almost rural suburbs (which, however, are not London), to conceive of the calm joy which a fair garden, situated in some tranquil, sequestered region, can minister to the mind. Here (Wigtonshire) the only sounds which come to my consciousness of an evening in May are the distant, muffled roar of the immemorial ocean, and the harmonising strains of the woodland singers—of the thrush and the merle, mezzo-soprano and contralto; the deep, intensely musical meditations of the ringdove, expressive of passion, strangely mingled with repose; sometimes the skylark, a singer of exceptionally high register, with a suddenly asserted supremacy, such as that of Ilma de Murska or Adelina Patti, soars impetuously above his sylvan contemporaries, like a spirit from his nest among the dewy grass, floating on waves of music to the skies. Anon the annual Cuckoo, who is always impressive in virtue of his possession of a unique individuality, and what Wordsworth entitled “a wandering voice,” arrests our attention, even as his forefathers were wont to do in the sunny days of childhood, with a sovereign sound.

It would be almost superfluous to quote from their writings the testimony of the greatest and most reverential thinkers to the tranquillising blessedness which a garden can afford; the benignant rest it invariably brings to the sadly wearied hard-wrought brain.

The purest, sweetest hours of Cowper were spent in his garden, and imagination loves to picture him there. Though Burns was not a gardener he was pre-eminently a “born” poet, and therefore also (for the greater circle includes the lesser) a lover of flowers. He had that instinct for the exquisite and ennobling in Nature which invariably characterises much more than mere mechanical or practical capability. His “Daisy,” as I can testify, grows almost as spontaneously in old-fashioned or even modernised gardens (where Nature has not been wholly excluded), as it does in the fields. He should have been a gardener rather than an agriculturist who wrote that sublimely pathetic picture of this glorified flower.

“Alas! 'tis no' thy neebor sweet,  
The bonnie Lark, companion meet,  
Bending thu 'mang the dewy weat  
Wi' speckled breast,  
When upward springing, blythe to greet  
The purpling East.

“Cauld blew the bitter, biting North  
Upon thine early, humble birth;  
Yet cheerfully thou glinted forth  
Amid the storm;  
Scarce reared above the parent earth  
Thy tender form.”

James Montgomery, too, had the horticultural instinct, deep reverence for Nature, and a constant consciousness of her divine significance; and he also, like Burns, has crowned with that halo of deathless interest, which only a supremely gifted singer can confer, some of our lowliest and loveliest flowers.

As much, and perhaps more, may expressively be said of Wordsworth, the High Priest of Nature, who terminates (and sublimates) his loftiest inspiration—the great Ode to Immortality—with those memorable lines:—

“Thanks to that human heart by which we live,  
Thanks to its tenderness, its joys, its fears,  
To me the meanest flower that blows can give  
Thoughts that do often lie too deep for tears.”

I am not quite certain that some of our modern gardens, with their geometrical lines of artificial beauty which would gratify Euclid much more than Linnæus, their formal gorgeousness of colouring, their closely clipped deformed Yews, and their all-prevailing barrenness of whatever is umbrageous, sheltering, or tranquillising, would have been gratifying to such passionate lovers of Nature as Cowper and Wordsworth. It is not, indeed, advisable in the arrangement of a garden to be too conservative; to have its borders so thickly crowded with overgrown bushes and dense flowering shrubs as to exclude from the noblest of modern Rose trees the pure light which they love, to render them the habitations and secure retreats of myriads of insects, which are a terror to every gardener who is working beneath their shade. But, on the other hand, let us not be too radical in our horticultural systems; let us be reverential when dealing with venerable trees, planted by loving hands now mouldering in the grave, for perhaps after all the unexpected beauties of the gardens of our forefathers, which met us at every turn of their winding, shadowy ways were more productive of joy to the artistic nature than the meretricious splendours of modern Art.—DAVID R. WILLIAMSON.

## HOEING AMONG VEGETABLE CROPS.

HOWEVER much we may be inclined to lament the long-continued drought, which will probably for years to come be remembered as a phenomenal occurrence, all must admit that it has been attended by advantages as well as drawbacks. Few will remember a springtime so favourable for preparing the ground, keeping young crops free from weeds, and getting the whole of the vegetable quarters into such a high state of culture as to render the work of keeping down weeds during the summer months a much less troublesome affair than it has been during the last few seasons. This is an advantage not to be lightly esteemed, for when once weeds are allowed to get the upper hand a vast amount of extra labour is incurred in eradicating them and their progeny, to say nothing of the injury done to crops in the early stages of growth, and the wastefulness of impoverishing the land by useless robbers. When, however, the surface of the soil is constantly stirred with the hoe, and the weather is bright and hot, there is but little opportunity for these robbers to become very voracious.

All successful cultivators, no matter whether they are gardeners or farmers, owe much of their success by first observing the great advantage to be obtained by constantly stirring the soil, and then turning that knowledge to practical account. Who has not noticed the rapid progress made by crops of all kinds when the hoe is kept constantly going among them, even when not a weed is to be seen? Many believe this is entirely due to the fact that by so doing weeds have no chance of establishing themselves, and the whole fertility of the soil is thus left for the use of the crops. The satisfactory state of affairs above indicated must, however, be attributed in a great measure to other causes; for although the prevention of the growth of weeds is one of the first principles upon which successful culture is founded, this practice does not in reality help the crops forward, but simply holds in check other vegetation which, if left, would impede the growth of them. Scientific research has proved that the very means we adopt to destroy these enemies of cultivated crops, at the same time places at the disposal of those crops a vast store of easily assimilated food. Although we necessarily place large quantities of manurial agents in the soil to replace the constituents drawn from it by our crops, yet it is nevertheless a fact that they derive the principal portions of their food from the air. It is thus clearly apparent that every time we stir the soil, air, and therefore food, is freely admitted; when once this undoubtedly fact is fully recognised by every tiller of the soil this free but indispensable food will be taken advantage of more fully.

Great as the above may seem, there are yet other benefits to be obtained by frequently stirring the soil. Spring crops are forwarded in a surprising way by the same practice, especially when the weather is bright, after a cold and protracted winter. The soil is then in a cold and wet condition, and takes much longer to be raised a few degrees in temperature than the atmosphere does. It is therefore easy to perceive that a few hours spent in hoeing among advancing crops lets in the air which has been heated by sunshine, causes the roots to be drawn to the surface to work freely among the warmer soil, and afterwards to penetrate deeper as the mass of soil becomes gradually heated. In hot dry periods such as we have lately experienced, a free use of the hoe is of immense benefit to crops generally, by checking evaporation in a way so well described by an “Old Gardener” in his interesting leader (page 329.) Of this I have had ample opportunities of judging recently, both in the flower and kitchen gardens, as it is only by persistently following that practice that many plants which could not be either

frequently watered or mulched have continued to make good progress, in spite of light soil and continued drought. Newly planted breadths of Lettuce, Cabbage, and Cauliflower, after receiving a few waterings have been so treated with good results; Onions, Carrots, Parsnips, Turnips, and Spinach have been hoed regularly since the young seedlings were first visible. In fact, our great aim has been to keep the hoe going in all directions when the state of the crops would admit of it, being fully aware that the practice is fraught with the advantages above enumerated, and that soil free from weeds and loose on the surface is in the right condition to receive full benefit from the rain when it comes.—H. DUNKIN.

## WINGLESS INSECTS OF THE FLOWER GARDEN.

(Continued from page 372.)

If we are to accept as correct sundry paragraphs which appear in some periodicals, not only during the "silly season," but at other times, the glow-worm beetle is much commoner than naturalists suppose, and often turns up in very unlikely spots. On investigation, however, it is frequently proved that the writer of a note on the appearance of a glow-worm is mistaken in his belief, the creature he has seen not being either the larva or beetle of the *Lampyrus*, the true glow-worm. One or more species of centipede, which are of common occurrence, have also the power of luminosity, though in a less degree as a rule, and can leave part of their light behind them upon the path they are travelling. According to one correspondent of *Nature*, however, the light of a small party of centipedes that he came upon produced an effect "like that of moonlight through the trees," and, coming closer, he was able to read by their illumination. I must own that I never came upon an electric or phosphorescent centipede quite as brilliant as above described. Recent experimenters have been trying to ascertain the cause of this light, and how its intensity may be increased or diminished; it is not very likely to be electrical, but perhaps it is phosphorescent. One thing is certainly clear, that these luminous centipedes have a source of light in themselves, and do not shine from having fed upon some other insect or animal that was luminous, or on some decaying vegetable substance, such being shown at times to emit light. What benefit the centipede derives from its luminous faculty we do not know; the light does not seem to be under the insect's control, though that is the case with some shining species, which withdraw and exhibit it when they please.

Should we see centipedes traversing a garden path some evening in summer—not an unusual thing—we may well spare the life of these humble crawlers, and let them shine on. In the flower garden, at least, the centipede does no harm compared to the benefits derived from its predatory habits, for it is probably rather a ravenous feeder upon the worms, young larvæ, mites, and slugs, which are its principal food. The presence of a poison-bag connected with the biting apparatus (the millipede, as previously stated, has feeble, unarmed jaws) shows that this insect is meant to kill, and in hot countries the bite of one of the large species is as much feared as that of a snake, but our small natives can do mankind no harm. It must sometimes happen that one of them is swallowed, head and all, by those hastily eating Strawberries, and stone fruit, into which centipedes manage to insinuate themselves. It is noticeable, that although fond of hiding, they seldom enter flowers, as earwigs do, but centipedes have an annoying trick of getting into the fingers of gardening gloves, also they lurk in flower pots; their advocates say their object in so doing is to prey upon the minute insect enemies of rootlets. Few people would suppose that the life of a centipede may last two years, yet such is the conclusion formed from its rate of growth.

One of the best known of the centipedes is that which Linnaeus called *Scolopendra electrica*, and which in consequence got the English name of the electric centipede. It has, or appears to have, no eyes, so that it cannot see its own light; the modern name for it is *Geophilus longicornis*—referring to its fondness for earth and the length of its antennæ. It has the look of a yellowish or dirty white thread, about 2 inches long, when it is noticed gliding along the soil with a wavy motion; but its love for the ground does not prevent it from mounting walls or trees to enter Plums, Apricots, or Peaches. Some persons think it enters fruit only already attacked by insects, or that are commencing to decay. During the digging of a flower bed in spring the females have been discovered coiled round like a snake within a cell they have scooped out, and watching carefully over their batch of eggs. Probably it is in the moist weather of spring and autumn that this and other centipedes are usually luminous. Another familiar species of our gardens is *G. subterraneus*, the light of which is more frequently noticed than that of the preceding. One observer describes it as coming from the head, shining out on each side of the insect at a slight angle; another states that he perceived it to come from the joints of the

legs, which I have also noticed, and this would account for the centipedes leaving a luminous trail that may extend a couple of feet behind; it is transferred partly to the fingers should the insect be laid hold of, and fades away by degrees. Though neither of these species has a hundred legs they make a good approach to that number, hence their nimbleness. Like their relatives, the millipedes, they may be snared by slices of Potato, and in flower pots their destruction is effected by the simple application of clear lime water or a petroleum solution, strength half ounce to a gallon of water.

A much stouter centipede is that named *Cryptops hortensis*; this is also eyeless, and has long, many-jointed antennæ, by the help of which it manages to travel about the world, and to obtain its prey. In colour it is yellowish brown, and so assimilates with the ordinary garden mould; the feet are generally forty when it is adult. Its relative, the rather smaller species *Lithobius forficatus*, does possess some small eyes just behind the antennæ; this has but fifteen pairs of feet, yet it is a nimble insect, as is proved by its having been seen in the act of capturing a fly. There is a small insect, occasionally abundant in gardens, which forms a link between the centipedes and the mites, the history of which has been elucidated by Sir John Lubbock. It is semi-transparent, scarcely the twentieth of an inch in length, and mostly lives where colonies of mites are to be found. It is an eater of vegetable substances only, and starts with six legs, but ends by having eighteen. It has been named *Pauropus Huxleyi*, after an honoured naturalist, and is an active, cleanly little creature, which makes itself busy frequently amongst the heaps of leaves accumulated for mould, and no doubt is useful by helping to disintegrate these, preparing them for the gardener unknown to him.—ENTOMOLOGIST.

## AQUILEGIAS.

BEAUTIFUL alike in form and colour, elegant and striking in habit of growth, this splendid genus ranks among the most useful of flowering plants at the present time of the year. Few things are better suited for arranging in vases in a cut state; the great length of flower stem to be obtained admits of their being arranged in a light and finished style. When grown in pots they are also much prized for disposing as dot plants in groups, and for placing in vases. A few of these disposed at intervals about dwelling rooms present a marked contrast to the more compact growth of the majority of other plants employed, and thus impart an amount of lightness combined with novel colour, which is not always easy to obtain.

Even the common species familiar to almost every cottager possesses great attractions. I have seen splendid masses of them growing in the woods on the deep sandy soils of Lincolnshire, where the Lily of the Valley was also luxuriating. The flowers of the native species, however, are altogether surpassed in the matter of variety and beauty of colouring by the many fine hybrids now in commerce. Veitch's new hybrids are especially good; from a single packet of seed flowers of many peculiar and beautiful shades of colour are invariably obtained. A large bed of these coming into flower at the present time is not only exceedingly beautiful, but also possesses more than an ordinary degree of interest, as many of the opening buds reveal a succession of surprises in the beauty of their colouring.

When a mass of one variety is preferred *A. californica hybrida*, with its yellow petals and orange-red spurs, is particularly good, and well adapted for pot work. *A. cœrulea hybrida* is also good for the same purpose, the petals being pale yellow, and the spurs light blue in colour. *A. chrysantha*, with its bright yellow flowers, is a grand plant for mixed borders or for planting in the front of shrubberies; when once well established in such positions, but little attention is afterwards required.

If seeds are sown at once, any of the above species will flower next year; to do this, however, they must be well grown, as the seedlings progress slowly in their early stages, for this reason I prefer to sow the seeds in pans placed in a cool frame. The pans should be well drained, using rather light soil with which a little powdered charcoal has been mixed; with ordinary care in watering there is then no danger of the soil becoming sour. The seeds should be just covered with soil, which ought to be made rather firm on the surface. When large enough to handle the young seedlings may be pricked out 3 inches apart, on a border which has been prepared by being well forked up, and then covered with an inch of finely sifted leaf mould or old potting soil. In pricking out care must be taken not to bury the crown of each plant, or progress will be slow. Shading should be given till the plants are established, and throughout the summer watering should be regularly attended to in dry weather.

The plants should be left in this position throughout the

winter, and in February or March, according to the state of the weather, be planted in their permanent positions; if in beds 9 inches apart, when in borders in clumps of five, or dotted irregularly to form single specimens. Any plants which are unduly weak should be lifted and replanted 6 inches asunder in nursery beds, and have the flower stems removed should any form. With this treatment fine plants are produced for the following season. These I find especially useful for flowering in pots. They should be potted in October, using a compost of two parts loam to one of well decayed manure, with a little sharp sand and wood ashes added. Pot firmly, winter in cold pits, and when the flower stems appear give liquid manure freely. When the plants require more head room than a pit affords, transfer to a cool greenhouse or conservatory, when they will quickly develop into beautiful objects, suitable for all kinds of floral embellishment.—W. H.

### FRUIT PROSPECTS—INSECTS.

THE fruit crops here are very promising without exception. Apples, Pears, Plums, Peaches, Nectarines, bush fruits, and Strawberries are well furnished with even crops. Strawberries must necessarily be small in berry, consequent on the long spell of dry weather, and no doubt all bush fruits will be undersized from the same cause. Raspberries in particular seem to have shown signs of distress in a marked manner.

Pears, both on walls and in the open, are above the average, and but very few trees are without fruits. These and Plums on walls were protected with fish nets while in bloom, and the weather being so dry frosts did but little or no apparent injury. Much thinning must be done to obtain full grown crops. Cherries of the dessert and Morello kinds are equally fruitful, but the dry weather thinned them somewhat, yet there are plenty left to mature. We can boast of but one Fig tree on the open walls, but this has many fruits of good size swelling freely, and had no protection in winter. The Gooseberry caterpillar made an early start on the bushes, and the colonies although attacked while very few in numbers showed great determination, but have disappeared since the cuckoo paid us a few visits in the early morning and late evenings. Of Peaches but few are grown outdoors, and the same apply to Apricots; but the trees we have are carrying a good crop of early fruits. Plums require considerable thinning.

On the gravelly subsoils the drought has told its tale. This I had ample witness of at Draycot, Chippenham, where trees of all kinds seemed to be suffering, and the crops in most instances were light as regards stone fruits, Apples, and Pears. Gooseberries, Raspberries, Red and Black Currants, and Strawberries looked well. Water is carted in large quantities, but without a heavy mulch and regular supplies Mr. Gibson finds but little benefit derived from such labour when the ground is so hot and dry as it was previous to the much-needed rains.

In Captain Spicer's gardens, Spye Park, there are, with few exceptions, fair crops, Red Currants being perhaps the lightest crop. This is attributed to frosts, which from the somewhat low lying situation of the garden often prove disastrous in spring. Plums on the walls are wonderfully even, and the trees in the best possible condition. Peaches and Apricots, too, are in a similarly fertile state, and very free from insects. Pears on walls are variable, some carrying a full crop, others being practically bare. Jargonelle and Williams' Bon Chrétien were both furnished splendidly; it is seldom that the first-named is seen so well set. Healthy young pyramid Plums and Pears planted by Mr. Perry only a few years since are almost devoid of a crop from the action of the spring frosts. However, there is an abundant promise, and with the unlimited resources in stable manure for mulching, dry weather has not the same influence that is known in too many gardens this spring.

Insects abound more or less everywhere, the fly on Plums and Cherries, and the caterpillars on Apples, Pears, and Gooseberries are only too common, but it is hoped the showery weather now set in will tend to mend matters somewhat. Black fly on Morello Cherries must have attention or the crop will quickly deteriorate, and I have found hellebore tea more effectual than any other dressing in making a clearance of this destructive pest.—W. STRUGNELL, *Rood Ashton Gardens, Trowbridge.*

IN "Notes and Gleanings" (page 375) you give the Board of Agriculture's advice in regard to some of these. There is no doubt that the amount of small caterpillar life is largely in excess of the ordinary quantity. For that, I apprehend, this extraordinary drought is responsible in large degree. The small moths, parents of many of these pests, are easily killed by a time of heavy rain—a large drop of rain hitting one of these tiny moths is nearly certain to put an end to its existence, or at any rate to incapacitate it from the roaming life which these little creatures evidently adopt—dropping one egg here and another yonder. I have little doubt that if these various applications reach the grubs, death results. But does it reach them? that is the question. I trow not! Most of those that injure our fruit trees belong to the leaf-rolling or leaf-closing tribe. Does this application ever reach them? I cannot think that one in a hundred is touched by them. Then as to aphides. These on Peach trees do not appear to me to take the stem; on the contrary, they are under the leaves, and these under the influence of the

punctures of these little pests twist about in various ways; but the result is generally that the curling leaf protects its enemy, and they are not seen even unless the leaf be unfurled. I wonder if the Board of Agriculture have tried the effect of their solutions on these. I have tried hard syringing on Peach trees against a wall, and the aphides remain lively and apparently none the worse. If the branches are loose and long enough that they can be dipped into a cup or basin containing the solution and stirred about in it, the pests may be reached, but this is not often the case; they seem to attack the short branches, with five or six leaves all close together and no length of stem, and the unhealthy appearance of these is the only clue to their existence.

As regards the maggots of the leaf-rolling kind, they are safe from the application, for even if put into a basin containing the solution I do not think it would reach the householder; and if it did, he probably would wriggle out the other side, and, dropping by his silken thread, alight on a neighbouring branch. If two leaves are glued together they safely enclose the grub, and if he has a sleeve he laughs in it at all the solutions. So again if the egg is laid, as is often the case, in the petals of the blooms, these are glued together, or three or four of the small fruit are thus fastened together, and the grub is safely protected there—the various fruits that go together to make the walls being all more or less injured. In fact, these fruits if spared can never be other than deformed specimens. My thoughts are directed not to orchards but to our wall fruit trees in gardens. I contend that the only safe plan is to cut off the leaf and burn it. Hand-picking is the only real safety, whilst in a year like the present, when Pears have set, as in some places, ten or more in a bunch, these should be separated and reduced to two, or perhaps only a single fruit. All these leaves and injured fruit must be burnt. Much may be done by squeezing the curled up leaves, but they do not improve the appearance of the tree. With most now the caterpillar has become a chrysalis, and if not stopped the young moth will soon be out again, and a fresh brood result. I venture to state that those who trust to these solutions are pinning their faith to broken reeds, and will be disappointed. Hand-picking may be tedious, but it is sure.—Y. B. A. Z.

### LATE DECORATIVE TULIPS.

BEFORE the Tulip season is quite ended I cannot refrain from calling attention to the wealth of beauty to be found in these flowers. Early flowering sorts are perfectly well known, though too often only as forcing plants, but the May blooming kinds are not represented in many gardens.

Some varieties which I bought many years ago as "breeders" or "mother" Tulips, and which hold something of the same position to florist Tulips that our beautiful self Carnations do to show varieties, seeing not one of them has ever changed in character, have yielded annually many gatherings of flowers as useful as they are beautiful. The stems of some of these are quite 3 feet long, while the colours of the flowers are indescribable, ranging as they do from fawn, soft blush, pink, crimson and violet, to deepest purple. One of the finest of all yellow flowers is a breeder named Bouton d'Or. There is another pretty variety called Picotee, but of the section to which this belongs I am not so sure, as the shape of the bloom is somewhat different. At any rate, it is indispensable, and is found in trade catalogues. In addition to these a number of T. Gesneriana, and of the more ruddy Oculus Solis, are indispensable. T. sylvestris we have in numbers in the woods, but it well repays cultivation. The form of the flower as well as the soft shade of yellow, and its delicious scent render it indispensable. Retroflexa is another yellow species of much beauty.

I once purchased some bizarres at a few shillings per 100, and no flowers have given more satisfaction than these. The ground colour is yellow marked with scarlet, maroon, and other shades. The description may appear rather glaring, but the flowers really are not so, they are brilliant and glowing, but without any hint of vulgarity in tone.

I am rather fond of monotone in arrangements of flowers. It is a simple and harmonious method, and there is no danger of mistaken contrasts. With Tulips, however, all colours may safely be employed together—purples, violets, yellows, reds and whites, and the effect is always good, just as it is if one shade or one colour alone is used. Tulips also harmonise well with other flowers, a few long-stemmed flowers giving character to an otherwise tame arrangement.

The time of day to cut Tulips is in the early morning, and the flowers should always be young. Placed with the stems in water for a few hours previous to packing they carry in perfect condition, and no flowers last longer in a cut state at this season of the year than they do.

I have seen it stated that Tulips succeed without cultivation, but that is not so. Some of the kinds which do not increase much succeed fairly well for years left in the same position, but as a rule the bulbs will be found to produce better flowers if they are occasionally lifted and planted in fresh soil. Sorts which, like T. Gesneriana, increase rapidly may be taken up every summer with advantage, and allowed more room. They do not require much space when grown in this way. If in rows put these at a foot asunder, and about five bulbs to the foot in each row. I find a surface dressing of superphosphate of lime applied early in spring has a most beneficial effect on the plants, the foliage comes stronger, the flower stems longer, and the flowers themselves of a greater size. The plants succeed in any position. I have some on a south, others on a north border. Many are grown in mixed borders, and the largest number in a quarter of Gooseberries.

While recommending these late-flowering Tulips I by no means wish it to be understood that the early blooming section should be ignored. I grow a large number of these; indeed, all the pot-grown bulbs are planted out, and in a short period these produce some useful flowers, although they are not quite so valuable as the others. Nor have I forgotten the quaint and richly marked Parrot Tulips; but of these I have grown comparatively few. At the same time these are proving so valuable that I hope to increase my stock for another season. Those who are totally unacquainted with Parrot Tulips may assure themselves that they are worth cultivating. The flowers are very large, and whether unexpanded or when fully developed they are equally beautiful.—B.

### GLADIOLUS COLVILLI THE BRIDE.

SOME two or three dozen pots of these extremely useful and chaste flowering plants are to be seen in the gardens at Draycot, Chippenham, where these, as well as Freesias, are always well grown. They are unusually strong and well flowered, and so sturdy are the plants that no supports are required to keep their handsome spikes, now open, erect. For house decoration in a cut state, or as pot plants, these are choice and beautiful. They are grown in turfy soil, leaf mould, and some decayed manure, and when growing freely get the benefit of weak doses of liquid manure often.

The secret of flowering these well is to thoroughly ripen the bulbs after their growth is completed, not by suddenly withholding water, causing the foliage to die away prematurely, but by standing the pots on a sunny shelf, and attend to them with their daily needs until signs of natural decay in the foliage are clearly apparent, when water can be withheld altogether. This is the treatment given by Mr. Gibson, and the results are satisfactory.

I find they will not bear much exposure to sharp frost in pots without injury; a portion of our stock plunged in ashes in a cold pit last winter were so crippled that they did not recover but few of them, and those that did do so are not strong enough to flower. Another gardener writing on the subject expressed his regret at the loss of several hundreds of his bulbs from the same cause. In the future, therefore, greater protection will be afforded these valuable Easter and Whitsuntide flowers, to avert such a serious loss which is now felt by their absence among the current season's display.

The plants at Draycot are growing in 6-inch pots, each containing seven bulbs, which, well grown, is sufficient to present a perfect individual specimen suitable for vases in the house, as dot plants in mixed conservatory arrangements, or any other use for which flowering plants are eligible. The bulbs in potting should be selected, keeping the stronger ones separate from small ones, or an evenness of flower spikes will not be secured.—W. S.

### LARCH DISEASE.

I WAS very pleased to read Mr. Molyneux's practical letter respecting the above in your issue of May 11th, answering my inquiry as to whether the disease is on the increase or decrease in the country generally. It evidently is not on the decrease in the district where Mr. Molyneux resides, but is as bad, or worse, than here. His account of it was all the more interesting to me as being from a district so entirely opposite to this both as to climate and composition of soil. Whilst the Swanmore soil there is heavy, and the subsoil chalk, ours is light loam in some places, sandy upon a subsoil of gravel or slaty rock. There is neither lime nor chalk in the soil, as is evidenced by the fact of Rhododendrons and other American plants flourishing very luxuriantly. We have moved some hundreds of bushes of all sizes, from 1 up to 12 feet in height of recent years, and all have done well, in fact they grow almost anywhere here.

Our Larch plantations are mainly on hillsides, and in most cases naturally well drained, and facing almost every aspect, but, like Mr. Molyneux, we have noticed that where the plantations are on a north aspect the trees have escaped the disease much better than elsewhere. This favours the theory that late spring frosts of the last few years have a great deal to do with the spread of the disease, as those on a warm position start into growth early, and are cut back, are the first to be attacked by the disease, whilst those facing north start much later, and are not attacked so badly.

The Larch aphid, or *Chermes Laricis*, is to be found in places with us, but not in such numbers as to do much damage. Our chief enemy is the canker. It has attacked trees of all ages, from three years up to twelve. We cut out about 12,000 diseased trees four years old from one plantation this spring. It is only about four years since the disease was first noticed here, but in that time it has made rapid progress.

The Spruce and Pines grow well here, and attain good dimensions; but they cannot take the place of the Larch as a timber tree, there being a great difference in their value. *Abies Douglasi*, which Mr. Molyneux says will not grow at all with him, thrives well here where we have planted it; but we have not planted it extensively, nor in exposed positions. I am afraid it will only do in sheltered positions. I should like to hear the experience of others who have tried it more extensively, also its value as a timber tree in comparison with the Larch.—R. C. WILLIAMS, *Crosswood Park, Aberystwith*.

EVENTS OF THE WEEK.—Apart from the Temple Show, which opens to-day (Thursday) under the auspices of the Royal Horticultural Society, and continues on Friday, but few events of special horticultural interest will take place during the ensuing week. The Gardening and Forestry Exhibition at Earl's Court, of course, is now open, and the customary auction sales at the various rooms will take place.

— THE WEATHER IN LONDON.—The current week opened with bright and sunny weather in the metropolis. Monday was also a glorious day, and the same may be said of Tuesday with the exception of the evening, when a slight shower fell. Wednesday morning was likewise fine, and as we are going to press the weather appears settled.

— WEATHER IN THE NORTH.—Abundance of rain has fallen during the last week, and the weather continues unsettled. A great deal of thunder has accompanied a half-hour's storm, on the evening of Saturday being very severe. The 22nd was a remarkably fine day throughout. The temperature has been high for the season, only on one night falling under 45°.—B. D., *S. Perthshire*.

— FLORENCE NARCISSUS.—I have had some bulbs of a *Narcissus* sent me. They have been cultivated near Florence, and are said to be the sort painted by the Italian masters of the fourteenth century. Can anyone oblige with name, saying if hardy? They somewhat resemble small *Tazetta* bulbs.—B.

— *HEMEROCALLIS FLAVA*.—Large patches of this fine old herbaceous plant are now in full beauty, the stately habit and bright yellow flowers making it one of the most attractive of hardy plants. Unfortunately the flowers do not last long, but either on the plants or cut and arranged loosely with foliage in vases they are very beautiful.—H. RICHARDS.

— OPENING OF A PUBLIC PARK AT ST. HELENS, LANCASHIRE.—On Thursday, May 18th, Taylor Park was formally opened by the Mayor, A. Sinclair, Esq., J.P., who received the deed of gift from the donor, S. Taylor, Esq., B.L. The park comprises 36 acres of land and 11 acres of water. Mr. Thomas Smeatham, late of Leaton Knolls, Shrewsbury, received the appointment of head gardener.

— POTATOES IN IRELAND.—According to an Irish paper there has seldom been a more hopeful promise of a rich yield in all descriptions of crops than at present. The Potato sets were put in during fine dry weather, which is of the greatest advantage, and all were planted in excellent time. New Potatoes were dug some weeks ago in Glandore, and they are at present comparatively common.

— SHOWER AND VICTORIA BOUQUETS.—I shall deem it a favour if information can be given on making the above bouquets. I have been a subscriber to the *Journal of Horticulture* for several years, and though, as you probably know, our winter occurs when it is summer in the old country, yet I have gained much useful knowledge from perusing your pages.—W. S. TANDY, *Fairview, near Pietermaritzburg, Natal*. [We will readily publish the desired information if any of our bouquet-making readers will favour by supplying it.]

— GARDENING APPOINTMENTS.—Mr. J. Wright, late gardener to A. Sarle, Esq., Green Hayes, Banstead, has been appointed gardener to H. O. Wills, Esq., Kelston Knoll, Bath. Mr. James Jones, after sixteen years as under gardener at The Larches, Preston, has been appointed head gardener to R. Fenton, Esq., Dutton Manor, near Longridge, Lancashire. Mr. Albert Pearce, for over two years foreman at Temple House, Great Marlow, Bucks, has been appointed head gardener to H. C. Jobson, Esq., Summer Hill House, Kidderminster.

— *ARNICA MONTANA*.—I quite agree with your note as to the beauty of this plant, but can anyone tell me if it requires any special treatment? I purchased a plant last summer which grew very slowly, and eventually died down in the autumn. It came up again in a very weak state this spring, and has now apparently collapsed altogether. This may be owing to the exceptionally dry season. Has any of your readers even seen a thoroughly vigorous plant of it, and under what conditions was it growing?—W. H. DIVERS, *Ketton Hall Gardens, Stamford*.

— THE GARDENERS' COMPANY were kindly invited by Sir Trevor Lawrence, Bart., the Master, and Lady Lawrence, to an "At Home," at their town residence, 57, Prince's Gate, on Saturday last.

— MONTPELLIER BOTANIC GARDEN.—The tercentenary of the foundation of this garden is being celebrated by a series of fêtes, which commenced on the 20th, and will be continued to the 28th inst.

— EAST ANGLIAN HORTICULTURAL CLUB BENEVOLENT FUND.—The Hon. Treasurer has received £22 15s., the profits arising from an amateur dramatic performance given by Messrs. Daniels Bros.' employés on 13th April, at Norwich.

— HERBACEOUS CALCEOLARIAS.—We are informed that at the Cheltenham Show recently Messrs. Sutton & Sons were adjudged a medal for a collection of Calceolarias, the only medal ever awarded by the Society.

— AGRICULTURAL AND HORTICULTURAL IMPORTS.—In the House of Lords recently the Earl of Kimberley moved, "That a Select Committee be appointed to consider and report whether legislation for the purpose of requiring the foreign or colonial origin of imported agricultural and horticultural produce, to be marked thereon or otherwise indicated, is necessary, expedient, and feasible; and, if so, what are the provisions which such legislation should comprise." The motion was agreed to.

— THE TEMPLE SHOW.—As notified in another paragraph, the great Flower Show held under the auspices of the Royal Horticultural Society opens in the Temple Gardens to-day (Thursday). A preliminary visit as these pages are passing through the press affords evidence that the Show in many respects equals those held on previous occasions. This year Orchids, as they hitherto have done, form a feature in the Exhibition. One large marquée is filled with Orchids, and some are staged in another huge tent with various exhibits. The Orchids are contributed by many of the leading growers, including Baron Schröder, Sir Trevor Lawrence, Bart., C. J. Lucas, Esq., Messrs. F. Sander & Co., Hugh Low & Co., J. Cypher & Sons, and B. S. Williams and Son. Ferns are extensively shown by Messrs. W. & J. Birkenhead, and hardy herbaceous flowers make a striking display, these coming from Messrs. P. Barr & Sons, T. S. Ware, Collins Bros., and others. Gloxinias are well represented, some grand collections being staged by Messrs. Sutton & Sons, J. Carter & Co., and J. Veitch & Sons, the latter firm also having hybrid Streptocarpus. Begonias are displayed by Messrs. J. Laing & Sons, H. Cannell & Sons, and T. S. Ware. Roses are not extensively shown this year. A detailed report will be given in our next issue.

— SUTTON'S IMPERIAL CABBAGE.—This is quite distinct from the well-known Wheeler's Imperial, so popular as a spring variety. We have a bed of several hundreds of each of these Imperial Cabbages, and the difference between them is very marked. Wheeler's is much the smaller and quicker in turning in, but the larger growing and later kind has its value, and a very considerable one too, in supplying a succession of heads of delicate colour, flavour, and crispness. It is not wise to depend on any one variety alone. A light sprinkling of nitrate of soda put on some time since and hoed in has had a marked effect, although not a drop of rain have we had since its application. Even in ground of good heart a sprinkling of this quick-acting fertiliser is a good investment, especially in a season like the present, in which the growth of most vegetables is slow.—W. STRUGNELL.

— CARNATION SOCIETY FOR WESTERN ENGLAND.—It has been thought by several growers and lovers of Carnations and Picotees in Western England that a good opening exists for the formation of a Society for the purpose of increasing the cultivation of these beautiful flowers in this part of the country. At the present time there is no show of Carnations held nearer than London, and it is thought that if annual shows, such as the Oxford and Midland Counties Shows, can be arranged for in the west, they would be appreciated by numerous small growers who do not care to go to the expense and inconvenience of sending to more distant shows, but would be glad to exhibit, if they could do so within a reasonable distance. Many of the large growers would doubtless exhibit, and those interested in the Carnation would be brought together and have the benefit of an interchange both of ideas and experience in regard to this subject. Mr. F. W. Baker of Keynsham, says *The Western Press*, is acting as Hon. Secretary of the movement, and Mr. J. A. Taylor of Warmley Hall is also interesting himself in its behalf.

— BOTANICAL LECTURES AT CHELSEA.—Mr. J. G. Baker, F.R.S., has commenced a course of botanical lectures and demonstrations in the gardens of the Society of Apothecaries, Chelsea. The lectures are given on Saturday afternoons at three o'clock, and are free.

— DISEASES OF PLANTS.—Italy is to the fore in the economic investigation of the diseases of plants, this work being carried on at two stations. One of the stations is at Pavia, established in 1871, and under the charge of Professor Brioni; and the other, established in 1887, is under the directorship of Professor Cuboni.

— ROYALTY AT FAREHAM.—Their Royal Highnesses the Duke and Duchess of Connaught honoured Messrs. W. & G. Drovers with a visit to their nurseries, Fareham, on Friday last. Their Royal Highnesses were received by Mr. W. Drover, and conducted through the houses. The Duchess evinced great interest in the growth of the Stephanotis, Gardenias, and Roses, and on leaving Her Royal Highness was presented by Mr. W. Drover with a bouquet of Perle des Jardins Roses and His Royal Highness with their new book on the "Growth of the Chrysanthemum."

— WHIT-MONDAY IN LONDON.—The weather in London last Monday was all that could be desired for a Bank Holiday. Nearly 70,000 people went to Hampstead Heath, 53,000 to the Crystal Palace, about 90,000 to Kew Gardens, 40,000 to Dulwich Park, 112,000 to Battersea Park, over 27,000 to the Zoological Gardens, 17,000 to the Tower, and 14,293 to the South Kensington Museum. In addition to these there were immense crowds at the Gardening and Forestry Exhibition. Thousands of people also visited Hampton Court Park, which was thrown open to the public without any formal ceremony.

— DESTROYING CRICKETS.—Being much pestered with crickets in our vinery, I shall be greatly obliged if any readers of the *Journal of Horticulture* will let me know of a better plan than I have tried—viz., beetle traps baited with sugar and treacle—for eradicating the pest. I should also like to ask if it is not very unusual for a cluster of Grapes to show from the extreme point of a shoot? There are only a few leaves on the shoot beneath the cluster, not one over it. I have left it from curiosity. The variety is Alicante, and the bunch should weigh about 4 lbs. if fully grown.—W. L. W.

— POLLINATION OF TOMATOES.—Anything from the pen of Mr. Iggulden is always acceptable, and I read with great interest his article on the "Pollination of Tomato Flowers" (page 350, May 4th). It may interest him and others to know that after perusing his article I was sufficiently interested to make a microscopic examination with a high power lens of the stigmas of two Tomato flowers—the one pollinated in the ordinary way by shaking the flowers, and the other in the way suggested by Mr. Iggulden. Both were well pollinated, and, so far as I could judge, there was no appreciable difference in the quantity of pollen deposited on the stigma.—CONSTANT READER.

— FLOWERS ARRANGED IN THE FRENCH STYLE.—There is no doubt that we have to concede a good deal to our neighbours over the Channel in matters of taste. Our solid insular perception refuses to lend itself to the vagaries of fashion and confectionery which are taken up and negotiated so airily by our charming and volatile friends. But if there is one of the lighter arts in which the French more excel than another it is in the arrangement of flowers. The solidified nosegays which we are accustomed to see in shop windows at home would be impossible to the most untaught *marchand des fleurs* abroad, and I, writes a correspondent in "Talk," am truly glad to see that an offshoot of this native talent has lately taken root in Regent Street, and bids fair to flourish there like the proverbial green Bay tree.

— THE WEATHER IN WARWICKSHIRE.—Writing from Warwick "H. D." says:—"The long wished for rain has come at last, and with no unstinted hand as far as this district is concerned. A steady rain of several hours' duration fell during the afternoon of Monday 15th inst., and continued at intervals during the night, amounting in all to half an inch. A few slight showers fell during the succeeding night. To-day, Wednesday, 17th, between twelve and two o'clock, we experienced a perfect deluge of rain. In a little over an hour the fall amounted to 1½ inch, and a series of steady showers continued throughout the afternoon and evening. Vegetation on every hand is responding with marvellous rapidity to the beneficial influence of life-giving rain, which has revived the drooping hopes of many a farmer and gardener, and converted trees, crops, grass, and flowers from a parched and weakened condition to one of the freshest vigour, not without high promise for future plenty."

—**FRUIT AS FOOD.**—Now that the fresh fruit season is at hand, will you allow me to announce that all your readers wishing to study the subject of a fruit diet, and how to adopt it, can obtain a packet of literature by addressing a postal wrapper to the "Natural Food Society," 78, Elm Park Road, S.W.? I ask this favour on the grounds of health and temperance, as well as because by the more profitable occupation of the soil for fruit, is become a question second to none in its bearing upon the solution of the social problem. Fruit, besides, contains elements of nourishment, contains also enough liquid to make drinking needless. After three years' personal trial, I can only add, "The proof of the pudding is in the eating."—W. S. MANNING.

—**EARLY PEAS.**—Our first pods of Sutton's Ringleader Peas were gathered on the 20th inst. from a sowing made on a south border February 25th, being exactly twelve weeks. They have not grown to more than half their usual height for want of root moisture, and the crop will consequently be a very short one. Sutton's Early Champion sown on the same date is only a few days later. American Wonder sown about the same time and forwarded under glass in boxes were ready a few days before Ringleader, but the quantity obtained scarcely repaid the trouble taken with them. No rain fell from the time of their being planted till they were ready for gathering. Unless Peas were sown at short intervals the supply cannot be easily maintained where demands are heavy.—W. STRUGNELL.

—**ELECTRICITY IN POTATO CULTURE.**—In order to test the conclusions of M. Spechnew, a French horticulturist, M. E. Lagrange, has cultivated Potatoes in a field divided into three parts, all of the same soil and exposure. One section was cultivated after the manner of Spechnew, the Potatoes being planted between plates of zinc and copper connected above the soil by wires so as to form earth batteries, with a current through the ground where the Potatoes were growing. The second section was cultivated in the ordinary way, without electricity. The third section was provided with small lightning rods thrust into the soil between the Potatoes until their ends were on a level with the tubers. The yield of the third section was much better than that of the other two sections, and was obtained fifteen days sooner. The ratio of the crops in the different sections were as 78, 80, and 103. The first section, although poor in roots, gave an exceptionally vigorous foliage.—(*Mark Lane Express.*)

—**HORTICULTURE IN THE NORTH.**—From a horticultural point of view the spring of 1893 is phenomenal, and the prospects for agriculturalists and horticulturists are very encouraging, observed a northern daily contemporary recently. The land in Northumberland and Durham is looking remarkably well, and the farmers are all in good spirits. Grass and seeds are in a wonderfully forward condition, and, given rain in the present month, the opening agricultural year augurs a rich autumnal ingathering. On the 6th inst. outdoor-grown Cornwall Strawberries were sold in the Newcastle Green Market five or six weeks earlier than previous "early" years. Last year it was about a month or so later that new fruit appeared in Newcastle, but a fortnight ago Gooseberries were sold at the rate of 4s. per stone, while Jersey Potatoes were disposed of as low as 21s. per cwt.—6s. or 7s. lower than the price at which they started last year. As an indication of the extremely forward state of fruit, it may be mentioned that Strawberries did not arrive in the Newcastle markets last year till June 18th.

—**FRUIT TREES ON RAILWAY EMBANKMENTS.**—Many French horticultural societies have petitioned the Government during recent years to substitute fruit for forest trees in the plantations made along railway routes. To these petitions, remarks the "Garden and Forest," the Ministry of Public Works has now replied by saying that, some twelve years ago it recommended the employment of fruit trees for the purpose named, that extensive experiments had since been made, and that these experiments had shown the inferiority of fruit trees to forest trees. Either the fruit trees had not flourished, or they had been pillaged and mutilated by marauders; and, moreover, they cast too heavy a shade, thus causing dampness and deterioration in road-beds near which they stood. "It is needful," says the explanatory circular, "that trees planted along tracks shall be capable of developing in isolation into tall slender forms, so that excessive shade may be avoided, and this requirement is best fulfilled by forest trees. Therefore the administration has renounced the attempt to popularise the plantation of fruit trees except in one or two departments, where a single species of nut-bearing trees will henceforth be admissible." In Belgium the case is about the same, and, indeed a Member of Parliament remarked, when the question was recently under discussion, that the only "trees" which should be planted along railway tracks were telegraph poles.

—**AN EDELWEISS FARM.**—A German horticultural paper calls the attention of tourists to the fact that they may be grievously deceived in thinking that the objects which they buy in Switzerland, decorated with dried blossoms of the Edelweiss, are really mementoes of the Alps. An enterprising horticulturist near Dantiz, on the northern coast of Germany, has, the "Garden and Forest" understands, established an Edelweiss farm, whence, last year, considerable quantities of the flowers were sent to a tradesman on the other side of the Alps, while this year the amount thus exported will be twice as large. The seeds are sown in tepid fertilised beds at the end of March or beginning of April, and are transplanted once before they are set out in the fields in July, after which it is only needful to weed the ground and loosen the soil around the plants.

—**POPULAR NAMES FOR PLANTS.**—Good illustrations of the difficulty of determining plants or vegetable productions by popular or local names are given in a letter by Mr. B. B. Smyth, of the Kansas Academy of Science, published in the current Quarterly Record of the Royal Botanic Society of London. "The name Nightshade," he says, "is applied here to *Solanum nigrum* and *S. triflorum*; the name Woody Nightshade is applied to *S. Dulcamara*; the name Bittersweet is applied to *Celastrus scandens*, a twining woody plant with clusters of showy scarlet berries; the name Laurel is applied to the different species of *Kalmia*; the names Mock Orange and Syringa are applied (of course misapplied) to *Philadelphus*; the name Sarsaparilla is (mis)applied to *Aralia*; the name Snakeroot is applied to a dozen different species in half as many different orders; the name Mouse-ear is applied to *Gnaphalium*, *Antennaria*, and *Cerastium*."

—**THE FRUIT AND VEGETABLE MARKET AT BRENTFORD.**—The new market, which has been laid out by the Brentford Local Board, was opened by the Lord Mayor of London on Wednesday, the 24th inst. The venture has been undertaken in consequence of the large proportions assumed by the market in the public thoroughfare near Kew Bridge, and the Board have received such support, not only from large growers in Middlesex and Surrey, but also from London salesmen and representatives of the northern English markets, that they regard success assured. It is intended for the wholesale and retail sale of market garden produce, flowers, and fruit, hay, straw, and general fodder. The whole of the stalls, it is stated, have been taken, and more than half the open stands have been allotted. Vegetables, fruit, and flowers will be on sale on Mondays, Wednesdays, and Fridays from four o'clock in the morning in summer and five o'clock in the winter.

—**CLIANTHUS PUNICEUS.**—What more interesting plant for training under the rafters of any ordinary greenhouse could be found than *Clianthus puniceus*, or, as it is commonly called, the "Parrot's Bill?" Introduced from New Zealand in 1832 this plant has had to give way in a great measure to the other species *Clianthus Dampieri* or "Glory Pea." The latter, although very beautiful, is not always easily cultivated, and to those who would perhaps like something less fastidious *C. puniceus* is worthy of being tried. Cuttings inserted in sandy soil in small pots and placed in a little bottom heat will soon root, and should be transferred to small pots, using a compost of good loam, leaf mould, charcoal, or red sandstone, and silver sand. After potting keep rather close, and use the syringe freely when the plants have become established in the new compost. When the small pots are filled with roots repot or plant out. In either case sufficient root room and good drainage should be given, and the syringe freely used. A little shortening back in the early season of the year is all the pruning it requires. A handsome plant, which covered the greater portion of the rafters of a span-roofed plant house, was recently in full flower at Walton Lea, Warrington, the residence of John Crosfield, Esq.—R. P. R.

—**TRANSFERENCE OF MATERIAL IN PLANTS.**—From recent researches on transference of material in plants (represented—*e.g.*, by transference of starch in the Potato), Herr Brasse is led to present the following view of what goes on. The assimilation of carbon in the sun's rays is manifested directly in deposition of starch in the chlorophyll grains. Through action of diastase in the leaves, and at a temperature lower than that of its formation, this starch is changed into reducing sugar, which spreads by diffusion from its place of formation into all the tissues of the plant. In certain parts, and especially in the tubers, the sugar is continuously transformed. The tubers, with regard to dissociation, act like the cold wall in vaporisation of a volatile liquid in an enclosed space. The sugar-content of all cells of the plant seeks to enter into equilibrium with that of the cells of the tubers, in which the content is less, because a change of sugar into starch takes place, and the co-efficient of this change is here less than that of the converse

change in the leaf, the temperature of the tuber being less. Owing to this inequality, there is a transference of starch from the leaf into the tuber, in which it passes through the intermediate stage of sugar. In a similar way Herr Brasse would explain the transference of nitrogenous and mineral plant materials, and their storage in special organs.—(*Comptes Rendus de la Société de Biologie.*)

— ROYAL METEOROLOGICAL SOCIETY.—The monthly meeting of this Society was held on Wednesday evening, the 17th inst., at the Institution of Civil Engineers, 25, Great George Street, Westminster, Dr. C. Theodore Williams, President, in the chair. Dr. H. R. Mill was elected a Fellow of the Society. The following papers were read:—1, "Mean Daily Maximum and Minimum Temperature at the Royal Observatory, Greenwich, on the Average of the Fifty Years from 1841 to 1890," by Mr. W. Ellis, F.R.A.S., F.R.Met.Soc. The author gives tables of the mean maximum and mean minimum temperature of the air on each day of the year, and also tables showing the daily range of temperature and the mean of the daily maximum and minimum values. 2, "Suggestions, from a Practical Point of View, for a New Classification of Cloud Forms," by Mr. F. Gaster, F.R.Met.Soc. The forms assumed by clouds at different levels, and under various conditions, have recently received considerable attention from meteorologists. The author, however, does not approve of the nomenclatures and classifications which have been proposed, as, in his opinion, they appear to be little, if any, better than the older ones they were intended to replace. He now proposes a somewhat different classification, arranging the clouds according to altitude under the following headings:—(1) Surface Clouds, or those which appear commonly between the earth's surface and a level of about 2000 feet; (2) Lower Medium Clouds, including all varieties which usually float at an elevation ranging from 2000 to about 10,000 feet; (3) Higher Medium Clouds, or those commonly found at altitudes varying from 10,000 to about 22,000 feet; (4) Highest (or Cirriform) Level Clouds, or those at elevations exceeding 22,000 feet. The author gives the names of each variety of cloud included in the classification, together with an account of the principal characteristics of each as far as appearance goes. 3, "Notes on Winter," by Mr. A. B. MacDowall, M.A., F.R.Met.Soc. In this paper the author discusses the question of periodicity in winters at Greenwich and Paris, and the relation of summers to winters.

— FLOWERING SHRUBS AT LAMPORT HALL.—On perusing some old numbers of the *Journal of Horticulture* one was found bearing date 20th June, 1872, giving an account of the Isham family, their family residence, and the Lamport estate and beautiful gardens. One sentence may be quoted, which is even of greater force now than when originally written—viz, "On the side of the park skirting the Northampton Road, Sir Charles Isham has indulged his love of trees and shrubs by planting it most profusely with scarlet and double pink Hawthorns, and other beautiful flowering trees and shrubs, to the great adornment of his policies and estate, and the delectation of the wayfarer, who cannot but be charmed with the beauties that thus cheer him on his weary way." At the present day this description is quite correct as far as it goes; but it is far short of the real state of things. For a distance of at least a mile and a half along the turnpike road towards the town of Northampton the red and double pink, interspersed with the white-flowering Thorn bushes, adorn the road. Just now these Hawthorns are beautiful, making the road peculiarly cheering to the wayfarer by their brightness and colour. It is no uncommon circumstance for people to drive from Northampton eight or nine miles at this season for the purpose of having a sight of the red and pink May, and to admire the beauties of the flowering trees and shrubs, which most certainly add grace and loveliness to the plantations by the roadside. Sir Charles Isham may be congratulated on his taste and the success of his attempts in thus beautifying his estate, to say nothing of the pleasure and gratification he affords to the community at large, for everyone who sees Lamport at this period of the year admires its beauty and expresses his pleasure with its charms. In this way Sir Charles is no doubt compensated for his pains and his outlay, which must have been considerable. Long may he live to enjoy the results of his labour and care.—GEORGE MACKINLAY.

#### DRACÆNA SANDERIANA VERSUS D. THALIOIDES.

"WHEN doctors differ who shall decide?" In Mr. Linden's note on the plants exhibited by him and Mr. Sander at the last meeting of the Royal Horticultural Society he says, "It is certain that the name under which I have shown this plant is correct," his authority being the Berlin Botanic Garden. Against this assertion we must place the

decision of Mr. Baker of Kew, not to mention others who have looked into the matter, which is to the effect that whatever the plant is that has been named *D. Sanderiana*, it certainly is not *D. thalioides* of Morren, nor does it agree with any other species of *Dracæna* described. In the herbarium at Kew there are good specimens of typical *D. thalioides*, and there is also a good representative living plant, which flowered in January this year, in one of the stoves.

This species may briefly be described as an erect woody stemmed plant a yard high, with leaves nearly 2½ feet long, the lower portion narrowed into a distinct petiole a foot long, the upper portion a flat lanceolate blade 2½ inches wide, gradually narrowing to an acute point. This agrees exactly with the plant figured by Morren as *D. thalioides*, and described by Brongniart as *D. Aubryana*. It appears to have been introduced and distributed under the former of these two names by Messrs. J. Makoy & Co., of Liege, before Brongniart described it in 1860. All this is, however, beside the point. It is quite clear that the Berlin authorities were in error in applying the name of *D. thalioides* to the plant discovered by Braun, and named *D. Sanderiana* by Messrs. Sander and Co. Mr. Linden can easily satisfy himself on this point by turning to the picture in *Belgique Horticole*, 1860, page 348.

The present state of the matter appears to me to be this: In 1888 Mr. J. Braun discovered in the German Cameroons a *Dracæna* which he succeeded in bringing alive to Berlin, where it was named in error *D. thalioides variegata*. A portion of the plants were secured by Mr. Bluth, a Berlin nurseryman, who disposed of them to Messrs. F. Sander and Co., who named the species in compliment to the head of their firm. The name is only provisional, as the plant has not yet flowered; but until it can be identified with a species of *Dracæna* already described, or unless it turns out to belong to some other genus, Messrs. Sander and Co.'s name for it must stand. It has no more to do with *D. thalioides* than with *D. Goldiana*.—W. WATSON, *Kew*.

DENDROBIUM THYRSIFLORUM.

THE plant represented in the illustration (fig. 75), which has been prepared from a photograph taken by W. A. Milner, Esq., in his picturesque garden at Totley Hall, near Sheffield, had thirty-nine racemes of bloom on it, but fourteen were taken off to throw more substance in the other twenty-five which remained. Some of the racemes measured quite a foot in length, and carried as many as sixty to seventy flowers on a spike. We have five plants of *Dendrobium thyrsiflorum*, but not so good a variety as the one depicted in the engraving.

The plants are potted in peat and moss taken from the moors in this neighbourhood when required. While making their growth they are put in an average temperature of 60° to 70°, with plenty of moisture both at the roots and in the atmosphere. When the growth is completed they are removed to a temperature of 50° and water withheld to a certain degree but not altogether, they being usually watered once a fortnight. The plants have as much sun and light as possible to ripen their pseudo-bulbs.—T. BIRKENSHAW, *The Gardens, Totley Hall*.

#### MAXILLARIA HARRISONIÆ.

THIS excellent Orchid blooms very freely during the winter and early spring months. All the parts of the flower are large and fleshy, and the two lower sepals are joined and elongated at the base, forming a sort of spur. The sepals and petals are creamy white, the lip purple and yellowish, with numerous lines of bright red in the interior. There are several varieties of *M. Harrisoniæ*, differing from the species mostly in the colour of the flowers, which in every case have a slight pleasing odour. A large number of generic synonyms exist, of which *Lycaste* is more common than any other, says the "Garden and Forest," although it is many years since Reichenbach referred the plant to the genus *Bifrenaria*.

*M. Harrisoniæ* and its varieties make most satisfactory progress in the cool Orchid house, the low temperature and moist atmosphere of which seems to suit them. Forty-five degrees, Fahrenheit, is a good average night temperature in winter, and strong sunshine should be guarded against at all times. A good supply of water is always necessary, and the drainage material should, therefore, be ample. The plants may be potted in rough peat-fibre, mixed with a little lumpy charcoal, any time after the flowering season.

## ODONTOGLOSSUM CITROSUM.

THIS is an Orchid which well repays the little trouble needed to grow it well, the long pendant racemes making it one of the very best for hanging baskets. It must be liberally treated to obtain the best results. A sunny position in the cool end of the Cattleya house will suit it perfectly. It requires plenty of water while making its growth, but when this is complete it must be kept quite dry until the flower spikes show in the top of the young growths in the spring.

## ONCIDIUM CUCULLATUM.

Good forms of this pretty little Orchid are very attractive, and the length of time the flowers remain fresh is greatly in their favour. The flowers are bright rosy purple, with darker spots on

Birmingham. This statement cannot be confirmed, as the specimen is not preserved in the author's herbarium. Schiede's specimen is very imperfect, having lost all its flowers, though there are four loose ones in a capsule attached to the sheet. One only has the lip denticulate at the apex, as in Lindley's description and drawing the others evidently belong to another species, but none of them agree with the one now described. If the flower just mentioned really belongs to Schiede's specimen, *P. carinatum* has flowers scarcely half as large as those of the present species. The lobes of the sepals of *P. Lindleyi* are deep orange-red or brick-red in colour, the tube and the rest of the flower light green. It may be placed next to *P. Loddigesii*, *Lindl.* Good specimens of *P. carinatum*, *Lindl.*, and *P. emarginatum*, *Lindl.*, would be welcome, as both are very imperfectly known.—(*Kew Bulletin*.)

FIG. 75.—DENDROBIUM THYRSIFLORUM.

the lip. A cool airy position, with plenty of moisture at the root, will ensure healthy plants.—H. R. R.

## PHYSOSIPHON LINDLEYI.

THIS is the largest-flowered *Physosiphon* known, the flowers measuring fully seven lines in length. A specimen, sent for determination by Mr. F. W. Moore, Glasnevin Botanic Garden, Dublin, in April, 1892, without any note of its origin, proves identical with a dried one collected by M. J. Linden as long ago as 1840 near Chiapas, Mexico. This specimen is wrongly labelled by Lindley "*Physosiphon carinatum*," a species described by him in 1838 ("*Bot. Reg.*," xxiv., Misc., p. 72), from a specimen collected by Schiede, near Sosocola, Mexico. Lindley also states that it had been obtained in a live state from Mexico by Mr. G. Barker of

## BULBOPHYLLUM RACEMOSUM.

THIS distinct *Bulbophyllum* is nearly allied to *B. anceps* (Rolfe, in "*Lindenia*, viii., p. 33, t. 351), which is also a native of Borneo. In general habit the two resemble each other quite as much as they differ from most other known species of the genus, but the present species has much larger flowers than *B. anceps*. They are honey-coloured, the dorsal sepals and petals spotted with maroon, and the lateral sepals minutely spotted on the upper half, and striped on the lower one with the same colour. The lip is purple, covered with numerous black dots, paler near the tip. The face of the column, also its foot, is spotted with purple on a pale ground. It flowered, says the "*Kew Bulletin*," in the collection of Sir Trevor Lawrence, Bart., of Burford, Dorking, last August, when it was sent to Kew for determination.

## ROSE SHOW FIXTURES IN 1893.

- June 20th (Tuesday).—Westminster (N.R.S.).  
 „ 22nd (Thursday).—Ryde.  
 „ 24th (Saturday) Reigate.  
 „ 28th (Wednesday).—Clifton,\* Earl's Court, and Richmond (Surrey).  
 „ 29th (Thursday).—Eltham, Newport, and Windsor.  
 July 1st (Saturday).—Crystal Palace (N.R.S.).  
 „ 4th (Tuesday).—Bagshot, Canterbury, Diss, and Gloucester.  
 „ 5th (Wednesday).—Croydon, Dursley, Ealing, Hereford, and Lee\*.  
 „ 6th (Thursday).—Bath, Farningham, Norwich, and Sutton.  
 „ 7th (Friday).—Hitchin.  
 „ 11th (Tuesday).—Harleston and Wolverhampton.†  
 „ 12th (Wednesday).—Earl's Court and Tunbridge Wells.  
 „ 13th (Thursday).—Worksop (N.R.S.), and Woodbridge.  
 „ 14th (Friday).—Helensburgh.  
 „ 15th (Saturday).—New Brighton.  
 „ 20th (Thursday).—Trentham.  
 „ 21st (Friday).—Ulverston.  
 „ 22nd (Saturday).—Manchester.  
 „ 25th (Tuesday).—Tibshelf.  
 „ 27th (Thursday).—Halifax, and Southwell.  
 „ 29th (Saturday).—Bedale.

\* Shows lasting two days. † Shows lasting three days.

I shall be glad to receive the dates of any Rose Shows not mentioned above for publication in my next list of fixtures, which will be issued early in June.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

## THE REIGATE SHOW.

WE are requested to state that in consequence of the early season the date of the Reigate Rose Show has been altered from July 8th to Saturday, June 24th.

## ROSE TURNER'S CRIMSON RAMBLER.

THOSE who, like myself, have visited most of the shows held in and around the metropolis this year cannot fail to have noticed the above charming Rose. It is perhaps one of the most showy Roses in cultivation. It appears to belong to the Polyantha class, and is a vigorous grower, hence its name. Most of the plants exhibited, however, and which I have seen, have been grown as bushes in pots, for which purpose it seems admirably adapted. The flowers are produced in clusters in immense numbers, and are of a brilliant crimson colour. So far as I can ascertain this Rose is quite hardy and may be grown out of doors, the introducer, Mr. C. Turner of Slough, claiming that it is adapted for growing on fences and walls.—ROSA.

## THE OLDEST ROSE TREE.

THE enclosed cutting, *re* the oldest Rose tree, from a newspaper may interest some of your readers, and I should like further information on the subject if it can possibly be obtained. The extract is to the effect that the "oldest Rose tree grows in Hildesheim, a little town in Hanover, from the cellar of the cemetery church. Its roots are in the cellar, and the original stem died long ago, but the young stems pass through a crevice in the wall, and cover with their branches nearly the whole of the church for 40 feet in height and width. The age of this Rose tree is interesting to both botanists and gardeners. According to tradition the tree was planted by Charlemagne in the year 833, and after a conflagration in the church in the eleventh century the root continued to grow in the cellar. Herr Roemer has now issued a pretty book about this venerable bush, and he proves that it is at least 300 years old. It is mentioned in a poem written in 1690, and also by a Jesuit writer who died in 1673. Even then it was very old, so that, even if we do not believe the tradition, it is the oldest bush known in the world. It is a Dog Rose, which may have been grafted; but since the death of the main stem its normal branches have grown. Another extremely old Rose tree grows in Ober-Haverbeck, at Soltau. Its stem has a circumference of 33 inches, while its ten branches attain circumferences of from 7 inches to 11 inches." What is the opinion of rosarians? —SUBURBANIST.

## THE CEDARS, WELLS.

THE Cedars, the residence of C. C. Tudway, Esq., is situated on the outskirts of the small but picturesque city of Wells. The group of Cedars from which the mansion takes its name is immediately in front, and divided from it by a thoroughfare named "The Liberty." These trees are of great age, and are said to have been exceptionally fine specimens. Time, with its erratic quota of warm smiles and cold boisterous storms, has evidently done much first to build up and consequently to maim and partly wreck these venerable trees.

Cedars are represented by magnificent specimens in the extensive grounds, *C. Libani foliis argenteis* being exceptionally fine at one end of the flower gardens. Along one side of the broad path which leads

from the mansion to the pinetum or coombe we noticed among other choice things symmetrical and mature examples of *Retinospora glauca* and *Cupressus Lawsoniana*, together with clumps of foliage and flowering shrubs, the whole forming a background for a long, narrow border, chiefly of herbaceous plants, deftly arranged to avoid the formal and rigid appearance so fatal to the effect of many arrangements in situations of this kind. Close to the extremity of this border is a large *Liriodendron tulipifera*, which yields immense quantities of its quaint Tulip-like blossoms in season for the many decorative purposes to which they are adapted.

Passing from the pleasure grounds proper to the interesting pinetum, which we enter on the south-east side, we are at once struck with the magnificence of the trees, situated as they are, some on the brow of a steep hill surrounded by dense undergrowth; others on the sward above, solitary, irregularly arranged, yet symmetrical and majestic in their individuality, associated here and there with dwarf foliage or flowering shrubs which render their large proportions the more evident. Beyond the initial preparation and planting little has been done to render the Conifers what they are now. The soil is a deep, reddish medium loam resting on lias rock, with here and there a black or greyish humus a few inches deep. Cedars are prominent again here, *C. Libani glauca* being very fine; *Pinus Morinda*, *P. sylvestris altaica*, *P. strobus*, *P. (Abies) cephalonica*, *P. (Picea) pinsapo* and many others are also good.

From the pinetum we come to a lawn, at one end of which is situated the finely appointed dairy, the manager, Mr. Walmer, being custodian of the coombe. Some of the rooms facing the lawn are fitted as a museum of curiosities, and are brimful with mementoes of the travels of various members of the family in many lands. The whole is clad externally with Ivy and trailing shrubs, and is extremely pretty. Returning along a winding path on the opposite side, and towards the point at which we entered, we passed huge Chestnuts, standard and bush Mays, and a multitude of other flowering trees and shrubs, which, viewed from the paddock below when in bloom, are said to be a gorgeous sight.

Fruit is largely in demand, and four roomy vineries and two Peach houses are heavily taxed of their specific products towards the supply. Mr. T. Wilkinson, who has been gardener here for several years, but who was about to leave for a more lucrative appointment at the time these notes were taken, has done good work among the Grapes, and indeed in all departments here. All the Vine borders were made, and, with the exception of one vinery, young canes planted under his care. He allows the laterals ample extension; in fact, the roof and front lights seemed covered with strong vigorous growths, more like healthy canes than laterals. The sub-laterals are pinched close. Immense crops of fine fruit are taken from these Vines annually, and if treated as well as they evidently have been in the past, will remain youthful and produce magnificent crops for a great many years to come. The roots are outside in rather wide and high borders, the surface bristling with small fibres. Feeding is largely done with sewage and Thomson's Vine manure. The Peaches and Nectarines were well furnished with medium-sized fruitful wood, and the houses densely packed with *Chrysanthemums*, of which about 500 plants are grown for large bloom. The Melon house at the time of my visit was full of flowering plants, a large plant of *Gloriosa superba* being in fine flower on the roof of one compartment.

The plant stove—a span-roofed house—contains many good things, including *Anthurium crystallinum*, with large shapely leaves; *Goniophlebium subauriculatum*, a very large plant with immense trailing fronds. Orchids are in evidence and in capital condition; two immense plants of *Cœlogyne cristata* with hundreds of pseudo-bulbs and many flower spikes. The leaves are long, glossy, and a very dark green. The plants are regularly and heavily fed with sewage. On a plant of *Cattleya Trianae*, suspended over the path, we counted seventeen flower sheaths, all robust, with every prospect of flowering. This is also treated to a course of sewage during the period of growth. *Lælia anceps* in the same position was carrying eleven flower spikes. *Cattleyas*, *Dendrobiums*, *Cypripediums* in variety, with a large batch of *Calanthes*; also *Sophranitis grandiflora*, and *Phajus Wallichii* are evidently at home in this house. The greenhouse in the same range and similar in proportions to the stove contained some large Indian *Azaleas* on the centre bed, the side staging being well stocked with *Primulas* and other softwooded plants. An advance is being made here with *Carnations* of the *Malmaison* type, a number of vigorous plants being in evidence.

A large and excellent selection of hardy fruit is grown, and there being a great deal of wall space protected with glass copings, much fine fruit is gathered. Mr. Tudway takes a keen interest in everything pertaining to the garden, and the collections both of fruits and plants are being steadily augmented.—W. R. W.

## EARL'S COURT SHOW.

MAY 18TH AND 19TH.

A SPECIAL Show of Orchids, miscellaneous plants, cut flowers, and fruit was held at the Gardening and Forestry Exhibition at Earl's Court on the above dates. Some exhibits were staged in the Exhibition buildings, but the majority of them were arranged in a large marquee in the grounds. It was not quite such a large show as was generally expected, although the plants and flowers staged made a good display.

In the open class for a group of Orchids and foliage plants Mr. H. James, Castle Nursery, West Norwood, the only competitor, was accorded the second prize. The group included *Cattleyas*, *Odontoglossums*

Cypripediums, *Lælia purpurata*, *Cymbidium Lowianum*, *Crotons*, Ferns, *Asparagus plumosus*, and Palms. Had there been more Orchids in this exhibit it would have been much enhanced in effect. In the amateurs' class for a similar group arranged for effect Mr. G. Wythes, gardener to the Duke of Northumberland, Syon House, Brentford, was awarded the first prize. This exhibit included *Cattleya Mossiæ*, C. Mendelli, *Cypripediums* in variety, *Dendrobiums*, *Odontoglossums*, *Lælia purpurata*, *Cymbidium Lowianum*, *Dracænas*, *Crotons*, Maiden-hair Ferns, *Caladiums*, and few large Palms. The plants in this group were finely grown, and arranged with admirable effect. Mr. W. Howe, gardener to H. Tate, Esq., Park Hill, Streatham Common, was accorded the first prize in the class for a group of *Dracænas*, staging fine clean plants. The second prize went to Mr. A. Offer, gardener to J. Warren, Esq., Handcross Park, Crawley, for a very meritorious exhibit, and the third to Mr. H. James. For a group of *Crotons* Mr. W. Howe was awarded the second prize, being the only competitor. The plants were fine, having a clean and healthy appearance.

Mr. Charles Turner, Royal Nurseries, Slough, the only exhibitor in this class, was awarded the first prize for *Pelargoniums*, showing magnificently grown plants of *Lady Carrington*, Duke of Norfolk, The Czar, Ellen Beck, East Lynne, Princess Teck, *Delicatum*, Gold Mine, Statesman, Ambassador, The Shah, and Magpie. Mr. C. Turner was again first for a group of *Souvenir de la Malmaison* Carnations. The plants were splendidly grown, and carrying flowers of extraordinary size and substance. This exhibit was undoubtedly a feature of the Show. For a group of *Roses* Mr. Turner was also first, showing beautiful examples of *Ulrich Brunner*, *Camille Bernardin*, *Thérèse Levet*, *Juno*, *La France*, *Margaret Dickson*, *Victor Verdier*, Mrs. Laxton, and Turner's *Crimson Rambler*. Messrs. Paul & Son, The Old Nurseries, Cheshunt, were awarded the second prize in this class, the group including *Princess Levet*, Dr. Andry, Mons. Furtado, Queen of Queens, Her Majesty, *Francisca Kruger*, *Céline Forestier*, and *Alfred Colomb*. Mr. Turner was likewise first for a group of greenhouse *Azaleas*. The plants in this group were symmetrical in shape and covered with flowers. The following varieties were well represented:—*Cordon Bleu*, *Madeleine*, *Reine des Pays Bas*, *Etendard de Flandres*, *Duc de Nassau*, *Jules Verne*, *Madame Van Houtte*, *Roi d'Holland*, *Jean Vervaene*, *Bijou de Paris*, Mrs. Turner, and *Bernard Andreas Alba*. Mr. A. Offer was awarded the second prize in this class, showing very creditable examples of *Souvenir de Prince Albert*, *Duc de Nassau*, *Madame Dupre*, *Brilliant*, and *Baron Stigula*.

Cut flowers were not so plentiful as might have been expected. The first prize for twelve bunches of cut Orchids, distinct, went to Mr. J. Prewett, Swiss Nursery, Hammersmith. The varieties shown were *Cypripedium Lawrenceanum*, *Cymbidium Lowianum*, *Odontoglossum citrosum*, *Cypripedium caudatum*, C. *hirsutissimum*, C. *Argus*, C. *barbatum*, *Cattleya Mendelli*, C. *Mossiæ*, *Lælia purpurata*, *Odontoglossum vexillarium*, and O. *Alexandra*. Mr. G. Wythes, gardener to the Duke of Northumberland, Syon House, Brentford, was a good second. The best flowers in this exhibit were *Lælia purpurata*, *Cattleya Mossiæ*, and C. *Mendelli*. Mr. J. Prewett was awarded first prize for a basket of Orchids. This contribution was charmingly arranged, the principal flowers being *Masdevallias*, *Cattleyas*, and *Odontoglossums*, set in *Adiantum gracillimum* and *Asparagus plumosus*, on a groundwork of *Adiantum farleyense*. Mr. G. Wythes was second with a less showy arrangement. Mr. Perry, gardener to J. C. Tasker, Esq., Middleton Hall, Brentwood, had a collection of *Canna* blooms, for which an extra prize was awarded. These flowers were very fine, and it is a wonder that they are not more generally grown. The best varieties were *Madame Crozy*, *Louis Thibaut*, *Progression*, *Sophie Buckner*, and *Edward Andie*. Messrs. Paul & Son, Cheshunt, had a box of single *Roses*, also plants of *Cannas* *Sophie Buckner* and *Comte de Ganay*, for which first-class certificates were awarded. Mr. Geo. Mount, Rose Nurseries, Canterbury, was accorded the first prize for a box of twelve distinct cut *Roses*. He staged beautiful flowers of *La France*, *Maréchal Niel*, *Ulrich Brunner*, *Anna Ollivier*, Duke of Wellington, Mrs. John Laing, Duke of Edinburgh, *Niphetos*, *Thomas Mills*, *Comtesse de Nadaillac*, *Catherine Mermet*, and *Jean Ducher*. The same exhibitor also staged a collection of cut *Roses*, for which a silver medal was awarded.

Miscellaneous exhibits were rather numerous and of a diversified character. Mr. Anthony Waterer, Knap Hill, sent a group of *Azaleas*, for which an extra prize was awarded. Mr. T. S. Ware, Hale Farm Nurseries, had a collection of hardy flowers. Amongst these *Spiræa palmata*, *Lilium Harrisii*, *Pyrethrums* in variety, *Inula grandiflora*, and *Irises* were conspicuous. An extra prize was awarded. Mr. Ware also had blooms of *Pride of Great Britain* *Carnation*. Mr. J. A. Morris, Acton, had two hampers of *Coleus* *Distinction*. Messrs. Sutton & Sons, Reading, were adjudged a silver-gilt medal for a splendid collection of *Perfection Calceolarias*. Messrs. J. Cheal & Sons, Crawley, sent a number of Apples, Pears, and hardy flowers, for which an extra prize was awarded. Mr. A. Offer showed a group of flowering plants, including *Erica Cavendishi*, *E. ventricosa coccinea minor*, *E. magnifica*, *Statice profusa*, *Hedera fuchsoides*, *Anthurium Scherzerianum*, *Aphelaxis macrantha purpurea*, all of which were examples of excellent cultivation. The group was deservedly awarded an extra prize. Messrs. W. Balchin & Son, Hassocks Nurseries, Sussex, were awarded an extra prize from a group of splendidly flowered *Leschenaultia biloba major*. Messrs. Peter Barr & Son, King Street, Covent Garden, staged a collection of herbaceous plants, for which they were accorded an extra prize. Amongst others were *Pyrethrums*, *Poppies*, *Tulips*, *Lupins*, *Gladioli*, *Centaureas*, and some grand *Pæonies*. The same firm sent a

splendid collection of *Irises* in variety, and some alpine plants, for which another extra prize was awarded.

Fruit was fairly well represented. In the class for three bunches of black Grapes, any variety, there were four competitors. Mr. J. McIndoe, gardener to Sir J. W. Pease, Bart., Hutton Hull, Guisborough, was placed first for three well coloured bunches of *Black Hamburg*. Mr. T. Osman, gardener to L. J. Baker, Esq., Ottershaw Park, Chertsey, was awarded second prize for *Black Hamburgs* of good size, but not so finely coloured as Mr. McIndoe's Grapes. Mr. G. Thompson, gardener to Messrs. W. & E. Wells, Hattenhurst, Hounslow, was third. Mr. McIndoe was also first for three bunches of white Grapes, showing fine examples of *Foster's Seedling*. The second prize went to Mr. E. Longley, gardener to W. J. Twigg, Esq., Croxted House, West Dulwich. Mr. J. McIndoe was again first for a dish of *Cherries*, staging some fine *Black Tartarian*. Strawberries were very good. For one dish, comprising twenty-five fruits, Mr. G. Norman, gardener to the Marquis of Salisbury, Hatfield House, Herts, was awarded first prize for splendidly grown *Auguste Nicaise*. Mr. W. Allan, gardener to Lord Suffield, Gunton Park, Norwich, was second with a dish of *Gunton Park Strawberry*. This is a dark coloured variety with medium sized fruits, which emit a delightful aroma. Mr. G. Thompson, Hounslow, was third, showing some well-grown *Sir Charles Napier*. Mr. G. Norman also staged half a dozen fruits of *Royal Sovereign* and *Laxton's Sensation*, for which first-class certificates were awarded. The first prize for three dishes of Strawberries also went to Mr. Norman. This exhibitor staged splendid fruits of *Vicomtesse Héricart de Thury*, *Competitor*, and *Sir Charles Napier*. Mr. W. Allan was second with *Lord Suffield*, *Empress of India*, and *Gunton Park*.

Mr. W. Robins, gardener to Colonel Lee, Hartwell House, Aylesbury, was first with six Peaches, showing splendid fruits of *Alexander*, well coloured. Messrs. T. Rivers & Son, Sawbridgeworth, was a close second with very fine *Hale's Early*, Mr. J. McIndoe following with well grown *Grosse Mignonne*. Messrs. T. Rivers & Son were first for six *Nectarines*, exhibiting grand fruits of *Early Rivers*. For a box of this variety, also shown by the same firm, an extra prize was awarded. Fruits of *Lord Napier*, small and green, were shown for comparison, these having been forced in the same house as *Early Rivers*. Mr. J. McIndoe was second with good examples of *Lord Napier*.

## WHITSUNTIDE SHOW AT MANCHESTER.

MAY 19TH-25TH.

THE great Exhibition of Orchids and other plants, which was opened at the Botanical Gardens, Old Trafford, on Friday last, and continues open until to-day (Thursday), formed a magnificent display. True, the competition was not so keen as one might have expected, but much care had obviously been expended to bring the exhibits to great perfection. The Orchids were arranged in the large Exhibition house, and, with the exception of the foliage plants, filled every portion of the building. The annexe was taken up with the groups of plants and Ferns arranged for effect, cut flowers, and a grand collection of *Rhododendrons* planted out, and belonging to Messrs. J. Waterer & Sons, Bagshot.

For the best miscellaneous collection of Orchids in bloom the prizes were £30 and £20. The former was taken by Geo. Hardy, Esq., with perhaps one of the most charming arrangements ever seen, and covering the whole of the east end of the Exhibition house. The background and sides were filled with foliage plants, the front being occupied by a dell of Orchids. In the central portion the larger plants were arranged, consisting of *Oncidiums*, *Lælias*, and *Dendrobiums*, several fine *Vandas* showing up well against the background of foliage. The frontal portion at each corner was divided from the central by walks of green moss, and here small *Cattleyas*, *Odontoglossums*, *Maxillarias*, and *Epidendrums* were admirably arranged, imparting sufficient tone of colour. The second prize went to F. Hardy, Esq., a son of the above named gentleman, and although containing excellent specimens, in many respects admirably grouped, yet there was a lack of finish through insufficiency of groundwork. In the nurserymen's class the prizes were £20, £15, and £10. Only two competed—viz., Messrs. J. Cypher & Sons, Cheltenham, and Heath & Sons of the same town. The former were well to the fore with an admirable arrangement throughout, containing splendid pieces of *Lælia purpurata*, conspicuous being *Hardyana* var., *Odontoglossums*, and *Oncidiums*. Messrs. Heath & Sons' group contained *Cypripedium Lawrenceanum* and *Lælia purpurata* in varieties.

For thirty Orchids in bloom only one competed, Thos. Statter, Esq., having a meritorious collection. The best were *Odontoglossum hastilabium* (onespike, forty-three flowers), *Cypripedium caudatum* in an 8-inch pot (thirteen flowers), *Lælia purpurata ponderosa*, *Oncidium superbiens*, *Epidendrum J. O'Brien*, and *Odontoglossum Pescatorei*. The prize in this class was a silver cup value 20 guineas presented by the late Earl of Derby. For the best collection of *Cypripediums* in bloom the first prize was a silver cup value 10 guineas, presented by O. O. Wrigley, Esq., Bury. George Hardy, Esq., was an easy winner, Mr. Cypher being second. For the ten best specimen Orchids a silver cup value 10 guineas was presented by Joseph Broom, Esq., J.P., Chairman of the Council. The same exhibitor was first with grand plants, the best being *Cymbidium Lowianum* (some twenty spikes), *Lælia purpurata* (twenty-six flowers), *Dendrobium thysiflorum* (seventeen spikes), *Cattleya Mossiæ*, (about seventy flowers, forty expanded), *Lælia purpurata* (very fine variety, deep lip, twenty-two flowers), *Dendrobium Wardianum* (thirty

spikes). Mrs. Hodgkinson was a good second with *Cymbidium Lowianum*, *Lælia purpurata* (twenty flowers), *Dendrobium splendidissimum* *Leeanum* as the best.

For a collection of *Cattleyas* Mr. Hardy was again first, showing a choice assortment, the best being *C. Mossiæ superba*, twenty-four flowers; *C. Marmorata*, twenty-six flowers; *C. Lawrenceana*, sixteen flowers; *C. Mendeli aurea*, and *C. Mendeli Firthi*. H. Shaw, Esq., had a collection arranged with Ferns, chiefly of the *Mossiæ* varieties, for second honours. The first prize, a silver cup, in this class was presented by Wm. Tattersal, Esq., J.P., Vice-President of the Society. The same gentleman secured the silver cup presented by Thos. Statter, Esq., for the best collection of *Dendrobiums* in bloom, staging eighteen plants, the most noticeable being *Dendrobium thyrsoiflorum*, *Walkerianum*, *nobile*, *Cypheri*, *Deari*, *crassinode*, *Bensoni*, and *suavissimum*. Mr. James Cypher was second. The best *bonâ fide* Orchid in the Show was staged by Mr. Hardy, the prize Williams' Memorial medal and £5 being awarded for a *Cattleya Reineckiana* with sixteen flowers. For the best collection of *Odontoglossums* in bloom (prize, silver cup value 10 guineas, presented by Geo. Hardy, Esq.), Wm. Thompson, Esq., was accorded first honours, the second prize exhibit being staged by F. Hardy, Esq. Thos. Statter, Esq., was first for the Sander prize, a cup value 15 guineas, for the best new Orchid in bloom, the favoured variety *Odontoglossum mulus Statteriana*. Mr. G. Hardy staged two plants in this class—*Odontoglossum Wattianum*, Hardy's variety, which ran the former very closely, and *Cypripedium Hardy-anum*, a finely flowered plant, which was struck out as being synonymous with *C. macrochilum*. Mr. Statter secured the Veitch Memorial medal and £5 for the best hybrid Orchid in bloom already in commerce with *Cypripedium Aylingi*, a pretty variety from *C. niveum* × *ciliolare*, carrying three flowers.

Herbaceous and alpine plants, Roses in pots, and Azaleas were not up to the usual standard, and call for little comment. For the former, a silver cup presented by S. Barlow, Esq., was won by R. P. Gill, Esq., Ashton-on-Mersey; second, Wm. Caldwell & Sons, Knutsford. James Brown, Esq., Longfield, Heaton Mersey, had Roses; and Miss Lord, Oakfield, Ashton-on-Mersey, Azaleas. For six bunches of Grapes, the first prize—silver cup, given by Dickson & Robinson, Manchester—went to the Duke of St. Albans, Bestwood, Notts.

The groups attracted attention. Messrs. R. P. Ker & Sons, Aigburth Nursery, Liverpool, secured first honours for a charming arrangement. The back portion was arranged in a sort of tier and balcony style, the latter extending prominently into the central portion of the group, and forming three half-circular recesses. These balconies and the background contained the usual array of foliage plants, whilst below the three recesses were filled with masses of well-flowered *Anthurium Schertzerianum* peeping from masses of Maidenhair Fern; then more to the fore a carpet of moss, with clumps of *Lilium Harrisii*, *Spiræa astilboides*, the two end pieces being made to represent tree trunks filled with small Palms and covered with creepers, the front being composed of an irregular band 2 feet wide of dwarf well-coloured *Crotons*, alternating with magnificent *Gloxinias* in flower. Nothing was crowded; the group was quite new in its detail, and the first prize worthily earned. The second prize went to Mr. A. J. A. Bruce, Chorltoncum-Hardy, for a grand arrangement, well mixed both as regards foliage and flowers, and a great credit to those who arranged it. The third prize was secured by Messrs. Heath & Sons. In the amateurs' class the prize was £15, and seldom has a finer arrangement been seen. The second prize went to Miss Lord with a superb group, the only fault one could possibly find being that much more could have been made had the plants not been arranged so flat. The groups of Ferns formed welcome additions, the first prize going to Messrs. W. & J. Birkenhead, Sale; the second to R. P. Gill, Esq.; third, Miss Lord.

Every praise must be given to the trade for the grand display they made, this applying to the Orchids and new and rare plants, and in this department Messrs. Linden (Brussels) and Messrs. F. Sander & Co. (St. Albans) ran each other closely. The former exhibited a fine and healthy collection, containing *Lælia purpurata alba*, *Odontoglossum Victorice* (hybrid), *Cattleya Warneri splendens*, *C. Acklandæ Salmonæ*, *Masdevallia versicolor*, charming *Bertolonias*, *Smilax argyrea*, and *Dracæna thalioides foliis variegatis*, and were unanimously awarded the Society's gold medal. The same award was made to Messrs. Sander and Co. for a splendid group, the most beautiful amongst the Orchids being *Sohralia macrantha alba*, *Phaius Sanderiana*, *Cattleya Mossiæ*, *C. Wagneri aurata*, *C. Loddigesi Measuresiana*, *C. Mendeli Sanderiana*, and *Odontoglossum crispum Owenianum*. The other new and rare plants from St. Albans comprised *Dipladenia atro-purpurea*, *Arisæma fimbriata*, *Alocasia Watsoniana*, *Acalypha Hamiltonianum*, *Dracæna Sanderiana*, *Strobilanthus Dyerianus*, *Pandanus Baptisti*, *Ceratolobus Findlayanus*, *Cincreria maritima variegata*, and *Maranta Leonice*. Messrs. Charlesworth, Shuttleworth & Co., Bradford, had a splendid group, admirably arranged, and containing *Oncidium macranthum*, *Grammotophyllum Measuresianum*, a fine piece with six strong spikes, *Oncidium Marshallianum*, *Cymbidium Lowianum*, and *Cattleya gigas imperialis*.

Extra prizes were awarded. Messrs. B. S. Williams & Son, Upper Holloway, had Orchids and flowering plants which made a feature of the Show. Messrs. Hugh Low & Co. had a most meritorious exhibit, prominent being a box of *Cypripedium bellatulum* containing twenty-four plants, *Cattleyas* and *Lælias*, and many others of choice merit. W. L. Lewis & Co., Southgate, had pleasing arrangements of Orchids, containing some really superb plants in the best of health, and Messrs.

Cypher & Co. for an artistic group of flowering plants, which made a pleasing feature in the annexe. Messrs. R. Smith & Co., Worcester, staged a fine group, containing well flowered *Clematis*, *Rhododendrons*, *Pyrethrums*, and *Pæonies*. Dickson Limited, Chester, made a fine display of cut flowers, in all some seventy vases. Messrs. Harkness and Sons, Bedale, had cut flowers and Roses, and W. Balchin & Sons *Leschenaultia hiloba major*. Messrs. J. Peed & Sons, Roupell Park Nurseries, sent *Caladiums*, and Mr. T. S. Ware a collection of *Pride of Great Britain Carnation*. Mr. James Mason, Ashton-on-Mersey, staged a group of miscellaneous plants, Miss Hopkins *Violas* and cut flowers, and Miss Lord herbaceous *Calceolarias*.

The Stott Company had a most interesting exhibit. Several certificates were granted.—R. P. R.

## BUTLEY TULIP SOCIETY.

THE sixty-eighth annual Exhibition of this Society was held at the Orange Tree Inn, Butley, near Macclesfield, on Friday last, May 19th, and there was a good muster of growers and friends. The flowers were numerous, and in most of the classes above the average in quality. The principal prize at Butley is a silver cup for the best stand of six rectified Tulips, one in each class, presented to the Society by the President, S. Barlow, Esq., of Stakehill. Six stands were staged for the cup, and the Judges awarded it to the stand exhibited by Mr. Barlow. His flowers were Sir J. Paxton, flamed bizarre; Garibaldi, feathered bizarre; Mahel, flamed rose; Heroine, feathered rose; Elizabeth Pegg, feathered byblœmen; and Talisman, flamed byblœmen. The stand was a first-rate one, especially the three feathered blooms. Mr. W. Kitchen of Marple had the next best stand.

### SINGLE BLOOMS.

#### Feathered Bizarres.

- 1, Mr. Barlow with Lord Stanley.
- 2, Mr. Barlow with Garibaldi.
- 3, Mr. Needham with W. Wilson.
- 4, Mr. Barlow with Lord Stanley.
- 5, Mr. Kitchen with Lord Lilford.
- 6, Mr. Barlow with Sir J. Paxton.
- 7, Mr. Kitchen with Sulphur.
- 8, Mr. Dymock with Seedling.
- 9, Mr. Bentley with Royal Gem.
- 10, Mr. Dymock with Seedling.

#### Flamed Bizarres.

- 1, Mr. Bentley with Sir J. Paxton.
- 2, Mr. Bentley with Sulphur.
- 3, Mr. Barlow with Sir J. Paxton.
- 4, Mr. Needham with Dr. Hutcheon.
- 5, Mr. Bentley with Dr. Hardy.
- 6, Mr. Bentley with Richard Yates.
- 7, Mr. Chadwick with Masterpiece.
- 8, Mr. Bentley with Wm. Wilson.
- 9, Mr. Bentley with Lord Sydney.
- 10, Mr. Bentley with Lord Delamere.

#### Flamed Byblœmens.

- |  |  |
|--|--|
| 1, Mr. Jones with Bertha.                | 1, Mr. Barlow with Adonis.                 |
| 2, Mr. Kitchen with Violet Aimable.      | 2, Mr. Bentley with Chancellor.            |
| 3, Mr. Dymock with King of the Universe. | 3, Mr. Bentley with Friar Tuck.            |
| 4, Mr. Jones with Bertha.                | 4, Mr. Kitchen with Talisman.              |
| 5, Mr. Kitchen with Bienfait.            | 5, Mr. Dymock with Lord Denman.            |
| 6, Mr. Needham with W. Parkinson.        | 6, Mr. Barlow with Adonis.                 |
| 7, Mr. Barlow with W. Bentley.           | 7, Mr. Kitchen with Stanley.               |
| 8, Mr. Jones with Mrs. Cobden.           | 8, Mr. Kitchen with Duchess of Sutherland. |
| 9, Mr. Bentley with Friar Tuck.          | 9, Mr. Kitchen with Prince of Morocco.     |
| 10, Mr. Bentley with Miss Johnson.       | 10, Mr. Dymock with Seedling.              |

#### Feathered Roses.

- 1, Mr. Needham with Mabel.
- 2, Mr. Kitchen with Edith.
- 3, Mr. Bentley with Rachel.
- 4, Mr. Barlow with Modesty.
- 5, Mr. Barlow with Madame St. Arnaud.
- 6, Mr. Barlow with Annie McGregor.
- 7, Mr. Kitchen with Queen Anne.
- 8, Mr. Jones with Industry.
- 9, Mr. Kitchen with Julia Farnese.
- 10, Mr. Chadwick with Mabel.

#### Flamed Roses.

- 1, Mr. Kitchen with Mabel.
- 2, Mr. Dymock with Queen Henrietta.
- 3, Mr. Barlow with Madame St. Arnaud.
- 4, Mr. Bentley with Mabel.
- 5, Mr. Barlow with A. McGregor.
- 6, Mr. Jones with Martin's No. 2.
- 7, Mr. Kitchen with Aglaia.
- 8, Mr. Kitchen with Triomphe Royale.
- 9, Mr. Dymock with Seedling.
- 10, Mr. Kitchen with Rose Hill.

### BREEDERS.

For the best three stands of three breeders, one in each class.

- 1, Mr. Barlow with Sir J. Paxton, Miss B. Coutts, and Alice Grey.
- 2, Mr. Kitchen with Sir J. Paxton, Olivia, and Wm. Bentley.
- 3, Mr. Needham, with Sir J. Paxton, Miss B. Coutts, and Bridesmaid.

### SINGLE BLOOMS.

#### Bizarre Breeders.

- 1, Mr. Barlow with Sulphur.
- 2, Mr. Barlow with Hepworth's 15/64
- 3, Mr. Bentley with Sir J. Paxton.
- 4, Mr. Jones with Dr. Hardy.
- 5, Mr. Jones with Unknown.

#### Byblœmen Breeders.

- 1, Mr. Bentley with Alice Grey.
- 2, Mr. Bentley with Bridesmaid.
- 3, Mr. Bentley with Glory of Stakehill.
- 4, Mr. Barlow with George Hardwick.
- 5, Mr. Barlow with Elizabeth Pegg.

### ROSE BREEDERS.

- 1, Mr. Barlow with Miss Burdett Coutts.
- 2, Mr. Barlow with Madame St. Arnaud.
- 3, Mr. Bentley with A. McGregor.
- 4, Mr. Chadwick with Mabel.
- 5, Mr. Barlow with Industry.

The extra prize for the best flamed flower in the whole Show was given to Mr. Bentley for Sir J. Paxton, and the extra prize for the best feathered flower was given to Mr. Jones for Bertha.

### SHOW PANSIES AND MR. PETER LYLE.

THE Pansy is essentially a Scottish flower, at once the most popular with first-rate florists and the most generally grown by the ordinary floral amateurs, from John o' Groats to Maidenkirke. The Show Pansy is a cross between our native *Viola tricolor* and *V. cornuta*. The raiser is unknown, as also is the date; but we may assume from various incidental circumstances that the fortunate man was from the neighbourhood of Paisley in Renfrewshire, and the period about the year 1823. Singularly enough, this is also the year when Mr. Peter Lyle was born, who, more than any other Pansy grower, has developed the flower by raising some of the very best sorts we yet possess, while from his youth he has kept true to the love of his heart, and is even now as keen and successful a grower of the flower as ever he was, as the grand beds he had to show last summer testified. While many districts in Scotland are associated with Pansy growing, such as Campsie, Newmilns, Vale of Leven, and others, Paisley has been the headquarters, and Kilbarchan, five miles west of the county town, has been noted for the enthusiasm of its florists, and may be counted as second in eminence.

When Mr. Lyle was but a lad his zeal for gardening manifested itself in real hard work. So anxious was he to get his father's garden dug that he has done it three times in one spring ere the right time came, with just "the sid" of weather to justify the sowing of seeds. The Pansy growers from whom Mr. Lyle caught "the fever" were Wm. Campbell, Duncan Cairney, James Dick, James Gilmore and John Love, the last named being figured in the *Journal of Horticulture*, October 1st, 1891.

Raising seedlings was the great hobby of the time, and when Mr. Lyle was twenty-five years of age, he went to his first show in Kilbarchan in 1848. Before that date shows had been attended in Paisley, and a few friends met there from time to time in the evenings to discuss new blooms, and Mr. Lyle had to walk home in the dark the five miles to Kilbarchan. To him this was no hardship, as he has ever been wonderfully quick of foot, and his fine constitution and wiry frame are even yet remarkably evident. In the year 1850, or thereby, a great show of Pansies and other flowers took place in Falkirk, but Mr. Lyle did not attend it, travelling thirty miles was not so expeditiously performed then as now. An old friend of my own, however, attended that show, Mr. James Peddie, gardener to John Gordon, Esq., of Aikenhead, Cathcart. As a gardener and keen florist the West of Scotland had no other to equal him, and his taste in Pansies was perfect. Mr. Peddie's first competition in Pansies was at Falkirk, and when he staged his blooms all eyes turned on the young fair-haired gardener and his stand of flowers. The Secretary, the late Mr. Charles Jeffrey, at once was struck with the stand and complimented the exhibitor thereon, saying "he was sure no finer lot would be shown, and that this would be adjudged first." It was so, and from that day the real Scottish taste for Pansies may date, as thereafter the flower was a leading feature everywhere. I cannot name the blooms which were shown at Falkirk, but the following were the varieties most in vogue about that time—viz., yellow grounds—Duke of Norfolk, Robert Burns, Gilbert Burns, Sir Charles Napier; white grounds, Miss Talbot, Lizzie, British Queen, Mountain of Snow; yellow selfs, Wonderful and Climax.

In Glasgow on 9th September, 1852, in George's Square, set out in tents, the tug of war came which decided the Pansy championship, and a full report was inserted in the *Glasgow Herald*. Here Mr. Lyle met Mr. Peddie, and was awarded the first prize in gardeners' and amateurs' classes for twenty-four blooms in each. A friend informed Mr. Peddie that he was surpassed by a man who had only 9 yards of a garden. This was true, yet could not be believed; so a gentleman was sent out to Kilbarchan to prospect, and on his return declared that the fact was so, and further that from the same plants in that small garden Mr. Lyle could stage forty-eight blooms any day, which would defy Scotland to beat them. It will be historically interesting to name the blooms as well as to show the source of our present stock as exhibited at Glasgow Show in 1852. The gardeners' class were: *White grounds*, France Cycole, Lady Mackenzie, Aurora, Royal Visit. *White selfs*.—Princess Royal, Jerome, Queen of England, Marchioness of Breadalbane. *Dark selfs*.—Rainbow, Duke of Perth, Norah, Maggie Lyle, Othello, Marchioness of Lothian. *Yellow grounds*.—Duke of Norfolk, Pizarro, Polyphemus, Juventa, Supreme. There were two seedlings and Elegant, Sir Wm. Rae, and Lucy Neale. In the amateurs' class they were somewhat the same, varied by Gulnare, Napoleon, Princess Louisa, and Robert Burns. It is well to note that while to-day we have not one of these victorious varieties, we have some with similar names, as Robert Burns, which is still grown, but not the flower then exhibited. Again, there have been two distinct "Royal Visits" to commemorate Her Majesty's coming to Glasgow.

From this date a universal taste for Pansies took possession of our florists. High prices were paid for a small quantity of rare seed, and very soon the increase in fine flowers became notable, while the standard of excellence was gradually raised for form, colour, texture, belting, blotch, and last, but not least, the eye. These six points must be met in a bloom, each point being nearly perfect, or, if one is deficient, the flower is condemned. Size may be counted the seventh point; as, however well up the Pansy may be otherwise, if it is less than 1½ inch in diameter it is not well grown.

Mr. Lyle's success continued, as he was a frequent prizewinner, notwithstanding the extended ranks of competitors. Then his seedlings were famous, only the real beauties being sent out by him. Of many sorts raised, he often gave those away which friends admired, and his name as raiser was never linked with them at all, while the gems were eagerly sought after, and high prices given for them. For instance, for two, named Capt. Spiers and Emily Lyle, the late Wm. Paul gave him £7; then for a beautiful one named Maggie Lyle he received £3 10s. from Messrs. Begg & Paul, who brought it out; while for twenty cuttings of one or two promising seedlings he would be paid £1. Nurserymen gladly add to their collections in this way, as amateurs usually concentrate their energies on one class of flowers, and the result is, as with Mr. Lyle, very special successes. A few of the most famous Show Pansies, raised by various florists, are as follows:—Countess of Roslin, Hugh Austin, Lavinia, Lady Lucy Dundas, Miss E. Cochrane, The Countess of Strathmore, and Flower of the Day. Of dark selfs some were really fine, and if Rev. H. H. D'Ombra could be rediscovered to-day it would be yet prized. This one endured for more years than any other. Irene was introduced by Mr. Middlemass, and was very fine. The Black Douglas, and W. B. Spiers and Gem followed—the last a beauty, but small, though as a judge said, it was "guid, guid!" The late Thos. Hastie, of Strathaven, raised one long esteemed by growers,

FIG. 76.—MR. PETER LYLE.

called James Dalzell, and which we still grow. Later Luna, and then Alexr. Watt, and David Malcolm brings the tale down to recent years. A white ground (Jane Grieve) was, however, the greatest wonder perhaps of any Show Pansy ever introduced.

The method of culture pursued by Mr. Lyle may be of service to many lovers of his favourite flower. The cuttings are taken in September and set in cold frames in good soil and a little sand, lightly watered, and closed and shaded for a week or so, and air gradually admitted afterwards. During winter the frame is not kept rigidly closed, but raised a little to allow air to enter and escape in all ordinary weather, but closed in extreme frost. It is damp which destroys the Pansy. In March, if any fly appears, a little softsoap dissolved in water is syringed on the young plants and the pest destroyed. This is repeated before planting out. In April the plants are set out, in soil new to them, as if planted again in the previous year's bed disease sets in. None but well-decayed manure is used, and this is dug in during the previous autumn. The soil is moderately rich and open; heavy clay soil will not do. After rains, when the earth is sodden, stir it freely between the plants with a hand-fork. This admits air, and the Pansy, though fond of moisture, cannot endure it to be stagnant. Until the plants grow and look robust, pluck off all the flower buds that show. When liquid manure is given it must be very weak, and in dry weather the plants must not be allowed to flag. As to the much talked of disease, healthy plants to start with are the best preventive; while new soil, in which Pansies have not been previously grown, will almost certainly keep back the invader.

Mr. Lyle's garden faces the south, and has been in cultivation for 150 years. Since he entered it, in 1861, it has only been trenched twice. Not a weed is to be seen, and though narrow it is long. In trade a joiner, he has always been employed at home, and therefore well placed to give his flowers regular care. Now, when nearing three-score years and ten, he finds enjoyment and exercise sufficient for his abounding vitality in his garden. His foot is still light and buoyant,

and his cheery spirit gay as ever. His children are away from home, one only having opportunity to develop the paternal taste for flowers. His wife and he dwell in their own property, and are comfortable and free from worldly care. In March Mr. Lyle will sow Pansies in seed boxes, prick out the seedlings in April into his empty frame, and plant in open ground in June, and be as happy in September over his seedlings, with many friends, as if toil and hardship had never been nigh him all his days. New sorts will be added to the long list he has raised, let us trust even superior to Mauve Queen, Mrs. Jno. Bolton, Marquis of Lorne, Mrs. Gladstone, Mrs. Arthur, and the rest of his floral achievements, the praises of which we see in all the Pansy catalogues.

Many have worked in the same field with him, but to Mr. Lyle is due, more than to any other single person, the honour of having raised the Show Pansy to the perfection it has now reached.—ALEXANDER SWEET.

#### FRUIT FORCING.

**Vines.**—*Early Muscats.*—Where these were started early in December, and they have been brought on steadily, the Grapes will now be ripening, and must not lack water at the roots. Examine the Vines every week, and if moisture be necessary give it liberally and at the mean temperature of the house. If the Vines have abundance of roots and are not exuberant, and the crop is heavy, supply tepid liquid manure, or top-dressings after moderate waterings, and wash in. The temperature should be maintained at 65° to 70° at night, with a little air at the top of the house, increasing the ventilation as soon as the sun acts on the house, keeping the heat at 70° to 75° on dull days, and 10° to 15° more from sun heat. Maintain rather dry warm air day and night, as the deposition of moisture on the Grapes is likely to produce spot, and its rapid evaporation from the berries results in scorching. No harm will occur provided proper attention is given to the ventilation, but if there is likely to be any danger arising from the border to the prejudice of the berries mulch it after watering with a couple of inches of short rather dry manure, and on this place about an inch thickness of coarsely chopped clean dry straw.

*Vines Started Early in the Year.*—Early Smyrna Frontignan, White Frontignan, Foster's Seedling, Buckland Sweetwater, Black Hamburg, Mill Hill Hamburg, and Madresfield Court are now ripening their crops, and though a rather drier atmosphere is desirable it is best secured by free ventilation. Have a little at the top of the house constantly, increasing it early in the morning, allowing a free circulation of warm air through the day. The inside border, also the outside, where the rainfall has not been sufficient to moisten it thoroughly, must have a good watering. A mulch of half-decayed manure will conserve the moisture and accelerate root action, which are necessary for the perfection of the crop and the health of the Vines. Good atmospheric moisture is essential to the proper swelling of the Grapes, the house being damped in the morning and in the afternoon until the berries are well advanced in colouring, when a drier condition of the atmosphere will be advisable. The temperature should be 65° at night, or 5° less when the Vines are heavily cropped and on cold nights, 70° to 75° by day artificially, increasing to 85° or 90° with sun and full ventilation, increasing this from 75°, and reducing it at 80°, at which close all but a small space at the top of the houses. Allow a moderate extension of the laterals, as a good spread of foliage without overcrowding is favourable to a perfect finish and the preservation of colour in the Grapes after they are ripe.

*Succession Houses.*—Stop or remove all growths not required, not allowing them to be made, and afterwards have to remove or reduce them in quantity, as it tends to a check favouring shanking. Let the laterals extend as far as space permits, not crowding the foliage unduly, but exposing the principal leaves fully to light and air, especially those that feed the pruning buds—those at their base for supplying the next year's crop of fruit. Thinning the bunches and berries must be attended to, removing duplicate bunches unflinchingly, and proceeding with thinning the berries as soon as they are fit. Supply water or liquid manure to the borders as required, yet avoid making the soil sodden and sour by needless waterings or cold and strong doses of liquid manure. Top-dressings of superphosphate encourage surface roots, and nitrates of potash and soda aid growth. Occasional sprinklings of the advertised fertilisers after a moderate watering and then washing them in improve the foliage and sustain the crop. A mulching conserves the moisture and is valuable where the soil is light and the roots near the surface, cow manure being best for light soils and horse droppings for heavy. A night temperature of 60° to 65° is sufficient, 70° by day artificially, ventilating from that point, and maintaining a good temperature (80° to 85°) from sun heat through the day. Close early, and increase the temperature to 90° or 95° with a plentiful supply of atmospheric moisture. Admit a little air at the top of the house before night, leaving the ventilation thus until it is necessary to increase it in the morning. An occasional damping of the floors and borders with liquid manure in

the evening greatly benefits the Vines, taking care not to produce too much ammonia vapour.

*Late Houses.*—The Vines are generally forward, and the aim should be to maintain the satisfactory progress by keeping a night temperature of 65°, 70° to 75° by day artificially, advancing to 80°, 85° or 90° through the day from sun heat. When in flower allow a night temperature of 70°, with 80° by day, and a free circulation of air, maintaining a genial condition of the atmosphere by damping available surfaces when they become dry. Attend to fertilising the shy setting varieties by brushing the bunches over with a camel's-hair brush to remove adhering caps and dispose pollen from the free-setting kinds over the bunches in a similar manner. Perform these operations carefully and not later than the early afternoon of fine days, preferably a couple of hours after the admission of more air. Remove duplicate bunches and avoid over-cropping and over-crowding the foliage as the greatest of evils. Commence thinning the free-setting kinds as soon as the berries are set; shy-setting varieties must not be thinned until the properly fertilised berries can be distinguished by their taking the lead in swelling. Reserve the best shaped and most compact bunches. Late Hamburgs need not be hurried.

*Houses of Ripe Grapes.*—When the Grapes are ripe fire heat will only be necessary to keep the temperature at about 60° at night, ventilating freely by day. Black Hamburgs will need a slight shade to prevent their losing colour. A single thickness of pilchard or doubled herring netting drawn over the roof lights will be sufficient. A moderate amount of air moisture is necessary for the benefit of the foliage, and it will not prejudice the keeping of the Grapes, but assist in preserving them plump, provided the atmosphere is not allowed to become stagnant. Encourage lateral growth, it tends to maintain the activity at the roots and to prevent premature ripening of the foliage, which must be kept clean and healthy as long as possible. Where fermenting materials were applied to the borders part of it may now be removed, leaving sufficient for a good mulch, and if the roots are active near the top a little fresh material may be placed on the surface to protect them from the atmosphere, but avoid heavy mulchings.

**Melons.**—Houses or pits in which the fruit is ripening will require a rather dry and warm atmosphere, allowing a circulation of air constantly, moderating the moisture at the roots. When the fruit is cut the growths may be cut back, a little of the old soil removed and fresh supplied, then the plants will soon make growth and set a second crop. Where, however, the plants are exhausted, or fallen a prey to red spider, they should be cleared out, the old soil removed, and the house be thoroughly cleansed. If fermenting materials have been employed for bottom heat, add some fresh, and mix with the top 12 or 18 inches of the old material, some of the most exhausted being removed. Make firm, and put in ridges or hillocks of good rather strong loam; if the loam is not calcareous add some old mortar rubbish and road scrapings. Tread the hillocks or ridges well down after they become warmed through, say in a couple of days. Make the soil firm about the plants, and the soil and balls being moist, no water will be needed until the roots have taken to the fresh soil. Shade from bright sun for a few days, and maintain a genial condition of the atmosphere by damping available surfaces in the morning and afternoon. Ventilate between 70° and 75°; keep through the day at 80° to 85° from sun heat, and close sufficiently early to increase the temperature to 90°–100°.

**Cucumbers.**—Plants that have been in bearing since the beginning of the year in a house may be cleared out, and the house being cleansed, it may be utilised for a late crop of Melon. If, however, the Cucumber plants are fairly healthy and the supply of fruit is still insufficient from pits and frames, they may be kept fruiting some time longer by removing the surface soil, and replacing with some lumpy loam, afterwards surfacing with some sweetened manure, giving a good soaking of tepid water or liquid manure. Thin out the old growths, and encourage young in their place. Shade from powerful sun, syringe the plants in the morning and afternoon, and damp well before nightfall. Fire heat need only be employed to maintain a temperature of 60° to 65° at night, and 70° to 75° in the daytime. Admit a little air at 75°, increase it with the advancing sun heat, keeping through the day at 80° to 85° or 90°, and close early in the afternoon so as to run up to 90°–100°.

Plants in pits and frames should be ventilated from 7.30 to 8 A.M., and in the hottest part of the day a slight shade from fierce sun will be beneficial, keeping through the day at 85° to 90°, close at 85°, and so early as to increase 5° to 10° or more from sun heat. Keep the plants watered as required, about twice a week being necessary in bright weather, and syringe them on fine afternoons. Avoid crowding the foliage, thinning well, keeping up a succession of young bearing wood, removing bad leaves, and stopping the shoots one or two joints beyond the show of fruit. Overcropping and allowing the fruit to remain on the plants after they become fit to cut greatly weakens them, and must be guarded against by timely thinning and cutting the fruit, which keep some time in a cool place, with the neck end inserted in a saucer of water. Straight fruits are not only handsomer and easier packed than the crooked, but they possess greater using value, therefore place the young fruit in glass tubes, or pieces of deal nailed together so as to form open ended troughs about 3 inches wide.

#### THE KITCHEN GARDEN.

**Work after the Rain.**—The rainfall would appear to have been general, and never was more welcome. All the hard lumps on newly dug quarters have been well moistened through, and before they again become hard or baked by sunshine all ought to be reduced to a fine

state with coarse rakes and hoes if need be. This will serve to keep the ground in a moist state, and admit of seeds being sown and plants put out in dry hot weather. Especially ought the spaces between newly dug Celery trenches to be raked over, and then Lettuce can be planted, or, better still, seed be sown at fortnightly intervals where the plants are to heart in. Ground from which Broccoli, Brussels Sprouts, and Borecole have been cleared is usually well adapted for Celery culture, and no time should be lost in preparing the rest of the trenches. When this work is deferred to near the time the plants are ready to put out, there is a likelihood of the latter being spoilt owing to press of other work delaying their being transplanted, whereas, if the trenches are ready for them, advantage can be taken of a showery time to get them out quickly and well.

Rain fell very opportunely for the Potatoes. These have come up very strongly and evenly, and the first proceeding should be to hoe; that is to say, loosen the soil rather deeply between the rows, this having the effect of breaking clods, letting in warmth and moisture to the roots, and destroying weeds. Many of the early and second early varieties have grown so rapidly as to be forward enough for moulding up, while the very earliest that could not be moulded up during the dry weather, owing to the lumpy state of the ground, are really too forward to be interfered with now, and are best left as they are. Better run the risk of the uppermost tubers greening than injure either the haulm or spreading roots by hoeing among them.

Brussels Sprouts, autumn Broccoli, and Cauliflowers should be planted among dwarf early Potatoes directly these have been moulded up, but it is only where the rows are not less than 3 feet apart that this ought ever to be done. Slugs have had a bad time of it lately, but will have made it plain they are not all dead ere this. Frequent surface hoeings among advancing crops serve to prevent the increase of slugs, also proving beneficial otherwise, and crops that are most preyed on should have soot and lime dusted among and over them as often as rains wash these fertilising slug-destroying substances away.

**Onions.**—Where the seed was sown rather early there are fairly good rows of plants to be seen, but in many instances the Onions present anything but a satisfactory appearance. Most probably much of the seed that has hitherto failed will germinate after the rains, and the beds should not be hastily condemned accordingly. It is always a mistake to delay thinning-out till the plants are too large to draw readily, and this season there is all the more necessity to thin early, in order that the thinnings may be replanted where there are gaps to be filled up, or fresh rows may also be formed. Do not thin severely unless extra fine "bulbs" are desired. Supposing the rows are nearly or quite 12 inches apart, leave the plants from 3 to 4 inches asunder; and if they eventually press against each other so much the better, medium-sized solid roots being the most serviceable, also keeping best. Allow another 2 inches or rather more if extra fine Onions are wanted. Replant the thinnings 1 inch below the surface, spreading out the roots carefully, and fixing the soil firmly about them. If dry weather prevails water occasionally till they are growing afresh. Liberal surfacings of soot hoed-in during showery weather acts as a preventive of grub attacks, and hastens the growth of the Onions considerably; so also do light surfacings of nitrate of soda, or that and superphosphate of lime and kainit at the rate of one part of the former to two parts of each of the latter.

**Carrots.**—The Carrot seed again has germinated badly; but most probably much that has previously missed is now showing life, and the beds, in any case, should not be hastily hoed over and sown afresh. It is not, however, advisable to delay sowing afresh more than a fortnight after rainfall, and it will most probably be found that late-sown breadths will give better results than has hitherto attended early sowing. The ground being in a moist, warm state, germination and after growth will be unusually rapid and strong, and if seed of Nantes Horn, Model, or other medium-sized or stump-rooted sorts, sown now, even in cold localities, will grow to their full size by the autumn, and keep quite as well or better than larger roots, and which also are the least appreciated in the kitchen. In warmer localities the Intermediate and long-rooted forms may also be sown with the certainty that they will be quite large enough for storing in the autumn. The drills for the smaller varieties should be drawn 9 inches apart, 1 foot being enough for the rest. Thin the former lightly, or according as the roots are required for use, and the stronger growers may be left about 5 inches apart in the row. Left thus thickly the roots will not be nearly so coarse nor so liable to crack badly as when allowed another 3 inches or more.

**Parsnips.**—These have come up better than expected, and as a rule are quite ready for thinning out. Very large roots of Parsnips do not keep well, and are a mistake in other respects, unless wanted for exhibition purposes. Instead of thinning to nearly or quite 15 inches asunder, those who are anxious to grow the most serviceable class of roots should leave the plants 9 inches apart. Some of the thinnings may be dibbled out where there are blanks, this being done more for the sake of appearance than utility, as the roots thus obtained are usually much forked.

**Turnips.**—Early sowings in the open failed badly, but those in frames succeeded admirably. Those who have been fortunate in obtaining a good plant should thin out the Early Milan and Early Munich rather lightly, leaving them say not more than 4 inches apart, and if drawing for use commences when the roots are not much larger than round Radishes the rest will soon attain a larger size. Snowball or other successional varieties do not thicken at the roots well if left closely together, and these, therefore, should be early thinned to about 9 inches

apart. Seeing that the variety last named and Veitch's Red Globe are much superior in point of quality to the early strap-leaved form it is these that ought now to be principally sown, a few short rows of Early Milan being included if a quick supply of roots are desired. Cool, moderately rich borders are the best positions for these sowings, the drills for the larger forms being drawn 15 inches apart. Slugs, flea, and such-like can be kept off by means of frequent dusting over with soot and lime.

**Spinach.**—If this must be had during July and August sow the seed thinly, in drills 1 foot asunder, on the coolest borders. The New Zealand Spinach is a fairly good substitute for the ordinary or true Spinach, and this revels in heat and sunshine. If plants have been raised singly in small pots, turn them out on to a warm border in succession to early Potatoes, disposing them not less than 3 feet apart each way. Seed may yet be sown in pinches where the plants are to grow eventually, leaving three to each patch. Where the tops are plentiful it is these that should be gathered and used as required.

**Tomatoes.**—The time has arrived for planting these out against sunny walls, fences, temporary wooden screens, or even in sunny quarters clear of wall shelter. In the three first instances the plants should be given good room, 12 inches apart answering for the compact growers, such as Conference, Challenger, Dwarf Champion, and Open Air; but Perfection, Sensation, and other vigorous forms should have another 3 inches. They may be either trained upright, or if the spaces between fruit trees are utilised, oblique training can be resorted to if need be. Give each plant the benefit of a good shovelful of fresh loam and manure, starvation treatment not being wise, though the other extreme is even more objectionable. See that the plants are in a moist state at the roots when turned out of the pots, and they ought not to become very dry for the next fortnight, the first bunch of flowers failing to set fruit when the old ball of soil and roots become dust dry before fresh roots have spread out into the fresh ground. Therefore plant deep enough to form a basin about the stems of the plants, and water every third or fourth day. Those planted quite in the open to be not less than 2 feet asunder each way, and these should be at once fastened to strong stakes.

#### PLANT HOUSES.

**Caladiums.**—Plants that it is intended to grow for conservatory or other forms of decoration in intermediate structures should be placed at once into larger pots. After the plants have started rooting freely in the new soil give them more air, so that firm sturdy growths will follow. Full sunshine may also be admitted to these plants. When grown under close, moist, and shady conditions their foliage falls directly the plants are placed in cooler and more airy quarters—in fact, they are practically useless for many forms of decoration.

**Achimenes.**—More cuttings may be inserted in 5-inch pots; these root quickly if placed in a moist shady position for a week or ten days, or in the propagating frame. The plants from which cuttings have been obtained should then be allowed to grow or to develop their tubers for another year. When once these are again fairly started into growth weak stimulants should be given them, or else they will grow weakly. Plants rooted some time ago and now in pots should be supported by four or five small stakes and one or two pieces of matting.

**Poinsettias.**—Do not keep plants growing in too close and warm a structure, or else they will draw up weakly and soon become leggy. They should occupy an intermediate temperature, and air should be given liberally when fine, which will result in sturdy growth. Young plants that need repotting ought to be attended to from time to time, and the soil should be pressed firmly into the pots; loose potting is a great mistake and only encourages soft rapid growth. These plants do well in fibry loam, one-seventh of manure and sand.

**Euphorbias.**—Cuttings of *E. jacquinæfolia* should now be plentiful, and will root freely if they have been prepared by thorough hardening in a cool airy house for the last fortnight. The young shoots should be taken off just where they are emitted from the old stem with a sharp knife, and if inserted in sandy soil and covered with a bell-glass, shaded from the sun, and kept in a close warm house, the majority will root. If the cuttings have been produced in brisk heat and are then inserted nearly every one will fail. Once sufficient young stock has been raised the old plants, if needed, may be cut back and allowed to start from the base.

**Asparagus plumosus nanus.**—Large or fair sized plants that display a tendency to form crowns may be divided into small pieces. The plants soon become established and are useful for various decorative purposes. Cuttings of *A. plumosus* and *tenuissimus* root freely. If portions of the stem with a leaf attached are inserted in sandy soil, in small pots, and stood under handlights in a warm house, every one will root, and by winter make useful decorative plants in small pots. Where larger plants are needed report those that have become too large in 4 and 5-inch pots.

**Crotons.**—Good heads that were taken off some time ago and are well established in 5 and 6-inch pots may be placed into larger before they become unduly crowded with roots; give each plant room to develop itself so that they do not become one-sided. Side shoots may now be taken from stock plants and rooted; these root freely in handlights in heat, if shaded from the sun, and will make good plants for many forms of decoration by autumn. Narrow-leaved kinds are very useful in a small state for table decoration, and these may be rooted in quantity, and when placed into 4 or 5-inch pots should be grown on a

shelf close to the glass. Plants that it is necessary to retain for stock may, when the cuttings have been removed, be cut close back and allowed to start from the base.

**Dracænas.**—Young plants should be repotted as they need more root room. Those plants that it is necessary to grow into a larger size, and which are now in 5 and 6-inch pots, should be placed into larger as soon as they are ready. These plants should be shaded for a few hours during the brightest and hottest part of the day, or else their foliage will colour too highly.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### THE APIARY.

THE weather is now showery and unsettled. Swarming is general, and as there is never honey during rainy weather both swarms and stocks will require attention in feeding. Stores of honey in stock hives will not prevent brood drawing at this season. The coming six weeks is the honey season from the Clover, and to make the most of it the bee-keeper must be careful to preserve the brood of the hive that will produce the honey-gathering bees during that eventful time.

#### SEALED QUILTS.

These are becoming fashionable and giving fanciers something to write about. These quilts are an American idea or rather bungle. A lady beginning bee-keeping last autumn had the top of a purchased hive sent to her covered with enamelled cloth. Although an entire novice in bee-keeping, and had not then seen the *Journal of Horticulture*, she saw the mistake, and writes to me, "I pricked holes in it with a pin." She did well, but would have done better had she removed it altogether and put in its place some porous non-conducting material and over that several inches dried grass.

#### DRONE BREEDERS.

There is scarcely a bee-keeper of my acquaintance who has not had a drone-breeding queen. Embrace the first opportunity now to raise nuclei for next year's work. We do not know what the weather may be further on, and "prepare early" should be the bee-keeper's watchword.

#### ENLARGING HIVES.

In all cases where the hives are not of a size sufficient for the laying powers of the queen steps should be taken to enlarge those too small, as previously advised. Another thing of importance wherever supers are used is that these should be made from the whitest of wood; bees have an inclination to make their combs of a similar colour to its surroundings. Some bee-keepers use the same supers for years, and as the bees soon darken the cleanest super, that with the accumulation of colour from years' use renders the honeycomb the reverse of appetising. Where the honey is used by the bee-keeper, if he is satisfied with used cases or supers nobody has a right to interfere, but in all cases where it has to go into the hands of strangers the clean super is the one that gives the most satisfaction and highest price. Cleanness and quality are the two cardinal points in bee-keeping, both as regards honey and wax.

After these comes quantity, if of the first standard, which is obtained in the highest degree without the extractor, honey ripener, spreading brood, reversible frames, excluder zinc, and as many more minor manipulations. During the past fifty years, and I believe for long before, with the exception of what comb foundation has done for us in assisting the bees greatly, there has been neither any improvement in the quality of the honey nor in its quantity from single hives. Doubtless bee literature has spread knowledge, but has not improved the quality nor the yield. Our large straw hives and Stewarton were then as they are yet, the foremost in the field. We have heard of great harvests being taken through the use of the extractor, but when the evidence came from a trustworthy source the yield did not exceed that of other well-managed hives in similar situations; but, as I have often said, that contests or competitions with bees and hives are futile unless the competition is conducted precisely under the same circumstances as to time and place.—A LANARKSHIRE BEE-KEEPER.

#### TRADE CATALOGUES RECEIVED.

T. S. Ware, Hale Farm Nurseries, Tottenham.—*Dahlias and Begonias*.

Kelway & Sons, Langport, Somerset.—*Plants, Trees, Seeds, &c.*

W. Clibran & Son, Oldfield Nurseries, Altrincham, Manchester.—*Store and Greenhouse Plants, Florists' Flowers, &c.*

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Vine Leaves Scorched (F. J.).**—The Vine leaf is very badly scorched. It arises from inattention to early ventilation, the sun being allowed to heat the tissue whilst covered or gorged with moisture. This is prevented by admitting air as soon as the sun acts on the house, the ventilation inducing steady evaporation, and the leaves then become warmed proportionately with the surrounding air.

**Thinning Potato Growths (E. F. D.).**—We have no doubt at all that two or three strong stems from a set give a better yield than would thrice that number of weak growths. The latter produce a greater number of tubers, but small in comparison with the others. When clusters of small stems have pushed from a set we have often thinned them with advantage to the crop, leaving only two or three of the stronger, drawing out the weaker when an inch or two above ground, or when hoeing between the rows the first time as soon as the plants were fairly visible. If you have doubts as to the usefulness of thinning, they will perhaps be dispelled by a well-conducted experiment. What we consider superfluous growths are as easily drawn out as if they were weeds; indeed, we consider them as such, as they deprive the soil of fertility without giving an adequate return. When thinning of the growths is resorted to it cannot be done too soon, late action not being nearly so effectual, and it may be of little or no service. The fault then rests with the individual, though it may not perhaps be easy to convince him of the fact.

**Leading Shoots of Vines (A Learner).**—These being intended to form rods should be trained not less than 2 feet apart for the small growers such as Frontignans; 2 feet 6 inches for moderate, such as Black Hamburgs; and 3 feet for strong growers like Gros Colman, on the extension system, but on the rod system they must be the usual distance asunder—1 foot more than just named. They may be trained their full length, the laterals pinched at every joint, and at the winter pruning the canes should be shortened according to their vigour, the weak the most, and the strong the least. By full length is meant the amount of space at command, the leader not being stopped until it has reached the limit. Some persons, however, stop the canes at about 9 feet of growth, pinch the laterals at the first leaf, and the sub-laterals to one leaf as produced, shortening weak canes to 3 feet, moderately strong to 4½ feet, and strong to 6 feet. Last year's canes should have the side shoots left 15 to 18 inches apart on opposite sides of the rods, alternately, stopping them at one or two joints beyond the show of fruit on the sixth to eighth good leaf and the laterals pinched to one leaf. A leader should be continued from the extremities of the rod, and be treated as before advised. The shoots from the spur will require disbudding, leaving one to each spur, stopping that retained a few joints beyond the fruit, and keeping the laterals stopped according to the space, not allowing them to become crowded. Every leaf should have full exposure to light and air.

**Trapa bicornis (T. W. E., Leeds).**—The above is the name of the plant to which your sketch refers. We cannot do better than repeat what we said about this plant last year. *Trapa bicornis* is a Chinese water plant, introduced into this country in 1790. The name *Trapa* is an abridgment of *calcitrapa*, the Latin name of a dangerous instrument called caltrops, furnished with four spines, which was formerly used in war to impede the progress of cavalry. *T. natans* is a curious aquatic with long brown and green roots and floating leaves, with petioles inflated into a tumour, as in the marine *Algæ*. The seed is larger than the kernel of the Filbert, with two cotyledons, one large and the other very small, and not increasing in size during the germination. Hence Gärtner considers this plant like the *Nelumbium*, as in a sort of middle state between the *Monocotyledonæ* and *Dicotyledonæ*. The nuts are farinaceous, and are esteemed as nourishing and pectoral. The skin with the spines being removed, there is a white sweet kernel within, somewhat like a Chestnut. They are sold in the market at Venice under the name of Jesuit's Nuts. They are also much eaten in Switzerland and the south of France. Some of the canals at Versailles are covered with the plant; and Niell informs us (*Hort. Tour.*) that the nuts are sometimes served up like Chestnuts. Pliny says that the Thracians made them into bread; and Thunberg states that the seeds of *Trapa bicornis* are commonly put into broth in Japan. In this country the

plant is generally kept in a cistern in the stove, and so treated was fruited by A. B. Lambert, Esq., in 1815, and specimens of the fruit sent to the Horticultural Society. *T. bicornis* is cultivated by the Chinese in marshes, and the nuts are used as food.

**Scented-leaved Pelargoniums** (*C. H.*).—You are right; the scented-leaved Pelargoniums are serviceable for decorative purposes. The following note, written by a gardener who grows them well, will exactly answer your questions:—Plants propagated now will remain useful until this time next year, or longer if desired. Young plants generally furnish the best shoots and finest developed leaves, but the plants may be kept on for several years and never fail to supply large numbers of side shoots. In beginning to propagate them the little side shoots should be taken with a small piece of the old wood attached, and this should form the heel of the cutting. They may be inserted singly into small thumb pots, or a number of them may be kept round the edge of a 6-inch pot. Any sandy soil will do for propagating, but they are benefitted by the help of a gentle bottom heat, and they should always have this if it can be supplied. We prefer putting the cuttings singly in the smallest pots, and then shifting them without breaking the young roots. This is the quickest way of obtaining large plants, as no check is given in repotting. As soon as a number of roots have been formed the cuttings should be withdrawn from the influence of the bottom heat and be placed in an intermediate temperature. Here they will soon grow rapidly, and may be repotted; 3-inch or 4-inch pots are large enough for the plants during their early days. They are placed in them from the cutting pots, and remain there until they have become bushy little plants. They are then shifted into 6-inch pots, and it is in this size that they become useful. At this potting good loam, a quantity of bone manure, and a liberal dash of sand should form the rooting mixture, and they will do admirably in this and in the 6-inch pots until they are a year old, but they must not be kept in a hot place constantly, as they luxuriate in a cool temperature. A sudden change from a hot place to a cold one should never be allowed, but after the first potting they should be gradually withdrawn from the heat, until by the end of May they are placed in a cool frame. There they may remain all summer, cutting from them as may be necessary, and pinching the points out of each of the leading shoots to induce a number of smaller ones to be emitted. They will soon come, and should be encouraged to grow for winter cutting. In the autumn, or by the end of September, the whole of the plants should be transferred to the greenhouse or conservatory, where they will be safe from frost and have the benefit of a genial atmosphere.

**Oxalis cernua** (*F. C.*).—This is an old plant, having been introduced from the Cape of Good Hope in 1767. It is of comparatively easy culture, and requires the following treatment:—After blooming the plants should be exposed in a sunny corner out of doors, water being gradually withheld. By degrees the leaves will assume a yellow tint, and finally fall off; and in this condition the pots containing the bulbs should be placed aside and kept perfectly dry until the season arrives for repotting them. If the ball of earth be then examined, a strong fibre may be traced from the surface-bulb quite to the bottom of the pot, and usually terminated by a cluster of young bulbs, each of the size of a nut. A pot planted originally with three bulbs will often contain, after flowering, a dozen or more full-sized roots, so that abundant facilities are offered for its propagation. At the base of the old bulb, which perishes, and also upon the short stipe proceeding from it, small offsets are often produced; but they are too minute to be available for the ready increase of the plant. At the end of September, about which time the roots will begin to grow, they may be repotted in sandy loam, with a little peat or leaf mould, planting them, if large, singly in a 4-inch pot about an inch below the surface; but it is preferable to place from three to five or six bulbs in one of rather larger diameter, a good drainage of potsherds or fragments of charcoal being indispensable. If the weather is mild the pots may remain in a warm nook out of doors, due precaution being taken to protect the plants from those pests of the gardener—slugs, snails, and worms; but on the approach of frosts they should be removed either to a cold frame, or, in the absence of this, to a cool window of south aspect, where plenty of air can be admitted in mild weather. A dry hot atmosphere is injurious to the plant; it should, therefore, be grown at a comparatively low temperature, and be removed to the sitting-room only when about to flower. If potted at the period named it usually begins to blossom about the end of March; but this depends in some degree on the temperature in which it has been kept. If the roots were preserved in a dry state until January or February, we think it highly probable that they might be planted in the open borders with the protection of a handlight, and would then flower in May and June, but without this covering it would be imprudent to risk the bulbs. The treatment of all the winter and spring-flowering species may be assimilated to that of the *O. cernua*.

**Preserving Fruit** (*St. Julien*).—We told you on page 381 that further inquiry should be made into the matter. It was made, and the result you will find, if you have not already done so, on page 410. However desirous we are to oblige correspondents we could not stop the press last week for the insertion of the article, which could not be prepared and sent sooner. It will probably not tell you all you want to know. No one has a right to expect to be taught everything on paper in a few weeks, and there are some things which cannot be learned from books alone; swimming is one of them, and preserving fruits and vegetables another. We are not prepared to say that the boiling for any particular period is absolutely necessary in the case of bottled fruit, but believe it to be most advisable. Why not test the matter for yourself, and then give the fruit-preserving fraternity the

benefit of your experience? You will most probably find that the fruit gently boiled for the period of time in each case, as given on the page cited, will be the plumpest, juiciest, and therefore superior, even if it does not keep any better than that which was only just brought to the boil, with a view of driving out the air from the bottles. If you will consult an expert pastry cook you will learn that parboiled fruit is the best for pies, as in this case the baking can be done quickly—the pastry, not the fruit, only being studied, and it is then light and wholesome accordingly. That, then, is a very good reason why bottled fruit should be boiled longer than you seem to think needful. With regard to the time that different kinds of fruit should be boiled during the process of being made into jam, we cannot advise other than in general terms. Everything depends upon the state and quality of the fruit, some requiring to be boiled very much longer than others owing to the extra "sloppy" or watery state of the samples to be treated. It must be boiled long enough to get rid of the superfluous water it contains, the best part of an hour being not too much in many cases. If it is boiled long enough for it to set, or prove fairly consistent when tested with a flat stick, there will be no difficulty about the preserve keeping. Those who have much preserving to do cannot wait for all fruit to be dry when gathered, nor is this at all imperative, although thought to be so by many housekeepers. There is no such thing as a precise time test in jam factories. The prices you obtain for produce, whether high or low, do not affect the general averages. More will be said on this subject, but all cannot be said at once, and there is not much gained, as a rule, by impatience.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*T. S., Grantully*).—We have received your letter, but the box referred to had not arrived when our pages were made up for press. (*T. F. S.*).—No. 1 spray from the Public Gardens, Bournemouth is *Cerasus scrotina*, the American Bird Cherry. No. 2, *Cerasus padus*, English Bird Cherry.

Bedding plants in variety.

### PROVISION FOR WINTER.

NEVER before have we seen pastures so bare in the third week of May as they were this year. On our journey from London to Chesterfield bare pasture was visible beyond the borders of Middlesex, right through Hertfordshire, Bedfordshire, Northamptonshire, and that part of Leicestershire south of Leicester. Some exceptions there were, but they were few and far between, pasture generally having very little herbage, some being quite brown and bare; Clover only a few inches in height was in bloom, spring corn was a thin weak plant, and much of the Wheat plant was unsatisfactory. The outlook for hay is therefore very bad indeed, much of the grass reserved for hay having been turned to for bare sustenance for the half-starved sheep and cattle. This has been done too in the northern part of Leicestershire, and in Derbyshire, where the herbage is altogether greener and more abundant. Quite refreshing was it to come upon really green fields and move a few miles beyond Leicester on the low-lying alluvial land through which run the Soar and the Trent.

As we write this article in Derbyshire, on May 17th, some fine rain is falling, and the barometer indicates more rain. If it comes now freely and quickly there may yet be some hay, but we have entered the eleventh week of persistent drought, and matters have become so serious that a special effort is called for in making provision of food for our live stock next winter. Judging from the enormous quantities of cattle Cabbage plants which we have seen at railway stations recently, efforts in this direction are being made. On every farm where land can be had Cabbage, Thousand-headed Kale, mixed corn and pulse for silage, Tares, mixed seeds, and roots should be sown or planted in the best way possible. Crops full and abundant are wanted, and must be had; with the rain which we may now expect to have seed germination and plant growth is certain to be quick; how vigorous it may also be depends upon fertility of soil. This ought not to be a doubtful matter at all; we have ample data for our guidance now in manure application, and if we err at all it should be in using too much rather than too little of quick-acting fertilisers when we sow or plant.

Take for example Turnips. We know that an average crop of 17 tons per acre absorbs about 150 lbs. of potash, 120 lbs. of nitrogen, 75 lbs. of lime, and 34 lbs. of phosphoric acid. Here surely is sufficient data to base calculations upon for the feeding of an ordinary or an extraordinary crop? It is only the farmer who has cultivated his land long enough to be intimately acquainted with its condition that can apply this plant food in the form of chemical salts with anything like precision. Even he must allow a liberal margin for contingencies, while anyone ignorant of how the land has been cultivated must make himself safe by using plenty of each manurial constituent. This would be working in the dark, but it would be safe enough. The all-important point is plenty of large sound roots for storage, plenty of small roots for leaving out or only covering slightly with soil. Practice, with science, will do this, but we must have both in happy combination with energetic action, born of the feeling that winter food there must be.

Let us be up and doing, then, striving to the very utmost of our powers to meet and overcome the difficulties of a season which, alas! has brought ruin in its train to many a struggling farmer, trained in a school where custom and habit were unfortunately the guiding principles. The season is altogether an exceptional

one, and exceptional means must be adopted to meet and overcome its difficulties. We must adapt ourselves to circumstances, not only now but always, and not rest content with simply drifting along. Well will it be if the difficulties of such an unkind season act as an incentive to face and overcome existing conditions generally. British agriculture has come to be regarded as a declining industry. Why has it failed to adapt itself to the state of the times? Is it because the British farmer is so badly educated in a technical sense? It has been said so, and probably with some degree of truth, but it is not that alone, it is also the lack of capacity to grasp the situation and to make a really judicious change. The laying down of entire farms to pasture is a mistake for which the farmer has paid dear. In such a season as this he is powerless to help himself by making any such provision for winter as we have indicated, all his dependance is in his pasture; if that fails him his difficulties may well appear insuperable.

### WORK ON THE HOME FARM.

The rain has come in time to render a crop of hay still quite possible, but the quick strong growth we require will only come on really rich pasture. Whenever there is a doubt of this, 1 cwt. or so per acre of nitrate of soda dissolved and brought quickly into action by the rain would do great good, but it must be used promptly and with the rain. The soil is so warm that growth will now be very brisk, and every effort must be made to thin-out Mangold, Swedes, Cabbage, and Kale as the plants become large enough. Weeds will certainly be troublesome, and both horse and hand hoes must be kept going as the weeds appear. Have all hand-hoeing done by the acre, and see that it is well done. Sow Maize now as we have recently advised, and any of the other green crops mentioned in our farm article this week. White Mustard sown now may prove very useful for sheep folding later on. Any bare fallow that could be well cleaned during the drought might be turned to account in this way, and the land would certainly be all the better for having the sheep upon it.

If possible, before grass mowing begins a rough outlying meadow will be pared, in order to get the sods dry enough for burning. This could not be done sooner, because the drought made the surface so hard that paring was impossible. The burning will be done at once if it can be managed, so as to destroy insect pests; the ashes will then be spread over the surface, and the ploughing be done at any convenient time before autumn. This field is wanted for green crops, and it will be sown with Oats for next season. It is, of course, optional to plough-in the turf without burning, but we much prefer to burn turf when it can be managed. This rough pasture has long been a nuisance with its coarse sedge-like herbage. It was a moot point whether to take it for Lucerne or for mixed cropping. Never has Lucerne been more useful than it has this season. It seems positively to revel in a drought, for while Grass and Clover near it are stunted in growth, it has continued growing in full vigour, affording a most valuable supply of sound green fodder.

### REMARKS.

14th.—Overcast early; bright sunshine from 9.30 A.M.  
15th.—Sunny, but shewing through cirrus or cirro-cumulus in morning; overcast afternoon, spots of rain in evening.  
16th.—Overcast almost throughout, with a shower from 1 to 1.30 P.M., but gleams of sun between 2 and 3 P.M.  
17th.—Overcast almost all day; thunder at 1.12 P.M., with slight shower; heavy rain with thunder and lightning at 4.15 P.M.; showers in evening.  
18th.—Overcast morning, with spots of rain at 10.30 A.M.; generally sunny after 0.30 P.M.  
19th.—Generally overcast and showery till 11 A.M.; much bright sunshine after.  
20th.—Dull and overcast, with slight rain at 9 A.M.; sun bright at 9.15 A.M.; shower at 12 noon; sun and rain up to 1 P.M., and cloud and sun after.  
The seventeenth warm week; but happily the drought has been broken after lasting as a "partial drought" seventy-eight days, a period very rarely equalled, certainly not since observations were begun here in 1857.—G. J. SYMONS.

### A GRAND CRUSH.

IF the character of the Royal Horticultural Society's Show that was held in the Temple Gardens on the Thames Embankment last week can be better condensed than in the above words we shall be glad to have the amendment for publication. It must be clearly understood that we desire to register what we believe to be a fact, and in no sense to suggest a reproach. On the contrary, we think the crush was more in the nature of a triumph, and for the Benchers of the Temple who granted the site, as well as the officials who conducted the Show, we have nothing but praise to record, the first for a kind act, the second for assiduous endeavour to turn to the best account they could the privilege accorded.

The Show was undoubtedly a magnificent one. The more it was examined the larger and richer it appeared to be; but it was a magnificent Show, marred, obscured, and in a sense spoiled by the crushing and crowding both of plants and people. The former could not be seen to anything like the best advantage, and the latter could not see with any satisfactory degree of comfort. The Royal Horticultural Society was represented in brilliant guise, but all the same in fetters.

The magnitude of the Show could not be appreciated in the cribbed, cabined, and confined space allotted, and the full beauty of the exhibits could not be half displayed. True, the tents were not small, No. 1 we believe measured 170×32 feet; No. 2, 150×40 feet; No. 3, 160×60 feet, and No. 4, 150×32 feet, or a ground area of 25,840 square feet. Surely someone may be inclined to say that such provision must have been ample. But it was not, and 50,000 square feet would not have been an inch too much to have enabled the Society to do justice to the material at its disposal, and to have permitted the public to enjoy the great floral feast.

We do not know whether there was space for any material extension of tents, or, if there were, whether the authorities would have permitted the extension. The Benchers are proud of their fine lawn, as well they may be of such a verdant expanse in the heart of London, and Mr. Newton certainly deserves praise for keeping it so fresh and bright during a season when most lawns are brown instead of green. He has evidently had plenty of water at hand and used it wisely. But assuming that the covered area could be doubled, and the plants and flowers displayed in picturesque freedom, with adequate space for their inspection, we are satisfied that a display of flowers could be provided in London that could not be excelled in any city in Europe, and equalled in few. It was essentially a "flower" show, and not an assemblage of lofty Palms, Ferns, and luxurious masses of foliage. More of these, with adequate space, would have been a relief—a foil to the great banks of Orchids, packed in such profusion as to be almost overpowering in their beauty. Some relief there was, undoubtedly, in the excellent specimen foliage plants from the gardens of Mr. Crowley, Waddon House, and Mr. Warren, Handcross Park, as well as in nurserymen's groups, yet these did not materially either lighten or subdue the great dense flat masses of flowers arranged as if for market.

The overcrowding was a mistake, and if the tent room could

not be increased a much better effect would have been produced and a more meritorious display provided by a diminution of the exhibits. There appeared to be a rivalry in endeavour to produce the greatest masses rather than the best examples of culture of the respective kinds, and the removal of a considerable number from some of the consignments would have enhanced the value of those remaining—the choicest and the best. It is a question if this massing method of showing is not being somewhat overdone, and it is becoming more and more impressed on the public that the Shows of the Royal Horticultural Society have grown into trade marts mainly. With three or four splendid exceptions—notably the incomparable Orchid groups of Baron Schröder and Sir Trevor Lawrence—comparatively little rivalry in cultivation was to be seen among amateurs; while gardeners, as a body, show no disposition to send examples of their skill to the Exhibitions. In this respect—and it goes to the root of the object for which exhibitions were instituted—there is a great departure from the shows of past times, when keen competition was the order of the day, and in which the greatest number of cultivators were encouraged to share. The Royal Horticultural Society's Shows incite rivalry no doubt, but it is practically trade rivalry and a question of covering the most space by packing plants together, not as affording lessons in tasteful arrangement or striking individual specimens, but of making a great display of produce for sale. In many instances this is certainly not done artistically, though some of the mixed groups were pleasing, effective, and suggestive; in these the representations of alpine plants in rockery mounds probably bore the palm, and they would have gladdened the heart of Mr. Arnott.

Next to the Orchids, hardy border flowers were most in evidence. The number was enormous, but most of the groups distinctly overcrowded. Tuberous Begonias were gorgeous, and if any person had prognosticated such massive and symmetrical blooms twenty years ago he would have been regarded as a dreamy enthusiast. The march onward in these flowers has been in advance of imagination. Gloxinias, Streptocarpuses, Roses, Pansies, Calceolarias, Petunias, decorative and "Improved Raspail" Pelargoniums were effective in blocks, in some instances relieved with Ferns or otherwise pleasingly disposed; and the group of Nectarine trees from Sawbridgeworth "took" immensely with the visitors.

It was a great, varied, and particularly a crushed and un-picturesque Show. A gentleman who came direct from the chief Parisian Show of the season—who, in fact, saw both Shows on the same day, was asked for his impressions. In numbers, richness, and value of plants the Temple Show he described as overwhelming, but for taste in arrangement and picturesqueness it sank very low in comparison, and with the Paris Show fresh in his mind he could only regard the one at the Temple as a great show spoiled by cramming. Crammed, indeed it was, with plants and visitors. The 170 feet long entrance tent was wedged with people panting in the heat and longing to "get out of it," and many who did so did not hesitate to say they had "had enough show" and passed to the lawn and the music. The central table in the entrance tent should never have been there, but it was inevitable for accommodating the exhibits, and the crowds had to push through as best they could without seeing half of them.

Twice the room was needed for the produce to be fully displayed and fully enjoyed. Neither was the case; the Show, we repeat, was a grand crush, and in that respect a great success. It ought to be so, and we hope it is, financially; but there were loud grumblings among exhibitors about the conditions attached to tickets, and visitors who wished to purchase plants also complained freely because there were no attendants with collections to take orders. The labour in connection with the Show was immense, and the zeal of the officials beyond praise.

## PRACTICAL HINTS ON MELON CULTURE.

*(Continued from page 309.)*

THAT large numbers of Melons may be grown in unheated pits during the summer months is fully demonstrated by a few skilful and energetic cultivators, who annually produce many fine examples entirely without artificial heat. Others there are who often try to do so, but unfortunately fail in their endeavours, and at length give up the task. This is to be regretted, because in almost any garden there are a few spare pits which may with advantage be devoted to Melon culture during a period through which they are of little use for other purposes.

Having had a large amount of experience in this phase of Melon culture, in some instances with marked success, I venture to jot down a few simple cultural details which, I trust, will help to bring success where failure has been too frequent. Pits which have been cleared of early Potatoes are often devoted to Melon culture. With these but little preparation is required before planting, as ample drainage is provided by the fermenting materials employed for the previous crop. Three inches of the surface soil should then be removed, and a mound of Melon soil (prepared in the way advised on page 267) placed in the centre of each light, the top of the mound to be slightly flattened when completed, and about 9 inches from the glass. A bushel of soil to an ordinary frame light is enough to start the plants in. When preparing pits or frames which have been used for protecting plants, it is better to provide some kind of drainage rather than place the soil upon the hard bottom. Three inches of clinkers or broken bricks answers the purpose well, over which a layer of rough manure or leaves should be placed before the soil is added. If, on the other hand, the floor of the pit is formed of rough boards with a hollow cavity underneath, the soil may be placed directly on the boards.

I always like to put out young plants from 4 or 5-inch pots before they have become root-bound, so that they have time to thoroughly establish themselves before the fruit begins to swell. The usual precaution of setting the collar of each plant only just deep enough to cover the old ball with fresh soil must of course be observed. After planting give a good watering with tepid water, keep close, and shade for ten days. Two plants should be planted in the centre of each light, and a few days after that operation is performed remove the point from each. Retain a couple of the strongest shoots resulting therefrom on each plant. Train one to the front and the other to the back of the light, stopping each shoot when they are within a foot of the side of the pit. Plenty of laterals will then be produced. These ought to have the points removed at one joint beyond the pistillate flower. Should the weather prove bright and warm the lights may be entirely removed for an hour during the middle of the day, to enable the pollen to become thoroughly dry.

After each fully expanded pistillate flower has been fertilised the lights ought to be placed on again, leaving an inch or two of air (according to the weather) on the back of the pit for a couple of hours longer, when they may be closed, without damping, taking care to admit air by seven o'clock the following morning if the weather is bright or warm. By following this practice I have never experienced any difficulty in securing a good set of fruit, and of retaining four of the most even ones on each plant. Every alternate lateral produced generally requires removal to prevent overcrowding; this is best done after the fruits are set, as there is then a better chance of securing even fruits in consequence of having more to select from. As a rule Melons in pits are managed successfully enough up to this stage of their growth, but by the time the fruits are half grown and the plants begin to feel the strain of the crop red spider, canker, and gum frequently begin to work sad havoc among them; but I have no hesitation in saying that with proper attention to watering, syringing, and ventilation these diseases and insects may generally be prevented doing much damage.

Care should be taken to ascertain the true condition of the soil before water is applied to the roots. This is easily done by thrusting a pointed stick into the soil. If this is found to be moderately dry a couple of inches below the surface a good watering may be given, but if once the plants are overwatered previous to a wet day, canker or decay at the collar is almost sure to follow. Watering is best performed early in the morning to allow the superfluous moisture to dry up before nightfall, an occasional supply of liquid manure being of great benefit.

Unremitting attention to ventilation is perhaps more conducive to success than any other operation connected with the culture of Melons in pits. It is not so much the giving of air which is sometimes neglected as the reduction of it. Seeing that the sun is the only heating medium we have to depend upon, it is absolutely necessary that a good amount of it be entrapped as often as possible. During bright weather a chink of air should be given at 7 A.M., a

little more being added an hour after, the amount being gradually increased as the sun gains power, and during dull periods it ought to be correspondingly reduced. Strict attention must be paid to this matter during the middle of the day, for it frequently happens that the sky becomes clouded then, and the sun fails to make its appearance again the same day, and unless the lights are quite closed at such times too little heat is maintained through the night. During bright weather closing should take place from 2 to 3 P.M., giving the plants a good syringing at the same time. Should the weather become suddenly dull at closing time, indications of rain being also present, syringing should be withheld and given early the next morning if bright weather is apparent, for in order to keep red spider at bay atmospheric moisture must be freely indulged in whenever bright weather is prevalent; but on the other hand stagnant moisture lying about the plants during dull weather when no fire heat can be given to dispel it, is productive of almost all the ills to which Melons are susceptible.

When the fruits begin to colour syringing must be sparingly indulged in, wetting those leaves only which can be done without damping the fruits, keeping the plants also rather drier at the roots, and shading slightly in hot weather. By the time the fruits are fully coloured water should be entirely withheld, and a little air be constantly left on. The ripening process is best completed by placing the fruits on a dry shelf for a couple of days. Diseases and insects I hope to deal with shortly.—LABOR OMNIA VINCIT.

## SHOWING AND JUDGING ALPINE FLOWERS.

WHILE it is evident that alpine flowers have not yet attained their proper position in the estimation of the public, it is equally evident that slowly but surely they are becoming more appreciated. This being so, it is to be expected that their claims for recognition at flower shows will be attended to, and classes for these attractive flowers more generally provided. It may therefore be assumed that the question of how alpins should be exhibited and judged is of sufficient interest to warrant the initiation of its discussion, and, with the view of eliciting an expression of opinion, these remarks are penned.

It must be evident to all who have at heart the progress of alpins that the general method of exhibiting these in pots or pans fully exposed to view is a most unsatisfactory mode of showing their beauties. The glaring colour of the earthenware is manifestly incongruous, and has besides, in many cases, the great disadvantage of "killing" the colours of the flowers. Then, again, pots or pans, while obnoxious on the ground of their colour and obvious want of harmony with the character of the vast majority of the plants they contain, are still more unsuitable for the many trailing plants which form such delightful objects when seen hanging over a large stone or depending from some crevice in larger rock gardens. Their beauty cannot be fully displayed by allowing them to hang over the edges of a pot, and in order to give them full justice some other method must be adopted. Two systems which may commend themselves to some only require to be mentioned to be almost "laughed out of court." These are either to surround the pot with one of those wire frames which are the horror of those who dislike to see flowers, in themselves of most beautiful pendant habit, tortured into the shape of a pancake that they may (save the mark!) display their beauty; or to reverse the order of Nature and train the plant to an upright trellis. Both of these systems condemn themselves, and we must endeavour to find another.

Much may be said in favour of the pots being placed in a bank of moss with sufficient space between to allow of room for the trailing plants to extend their branches, but, on the other hand, the very beauty of the moss would in some cases prevent the flowers fully displaying their delicacy and loveliness. We must, therefore, I submit, take a lesson from Nature, and adopt the plan which has already commended itself to a few exhibitors of arranging the plants among pieces of rock so placed as to hide the pots or pans, and to display the form, habit, and colour of the flowers as well as possible. To do this properly the pieces of rock should be weather-worn and coloured, and perhaps no stone is so suitable as that which seems to be the favourite of so many gems of the alpine flora—limestone.

Another question which arises, and which is one of very considerable difficulty is, What is an alpine? Here, I must confess, I am puzzled to give a definition which would fully convey my meaning, and which would properly discriminate between a hardy border flower and an alpine, for some true alpins will grow admirably on many borders, and no hard and fast rule can be laid down. At the same time it is evident that many comparatively gross growing flowers are shown in classes for alpins, and there is a danger that these may, by their more showy appearance, be considered

more worthy of an award than others which come more properly under the category of alpiners, and although less showy would commend themselves to a connoisseur—a word I do not care for in this connection, but which expresses better than any other my meaning.

Now the consideration of these remarks leads me to what is I think a natural conclusion, *i.e.*, that the conditions on the exhibition schedules must be so expressed as to guide both judges and exhibitors in their work. May I thus submit for consideration and amendment, in a similar way as we had recently done in the discussion on the showing of hardy border flowers, the following? "Best — pots or pans of alpine flowers of neat and dwarf habit; to be arranged in a natural and artistic manner." I do not consider this absolutely perfect, but submit it for the freest criticism and comment.

I now come to what is perhaps the most delicate portion of my subject, inasmuch as it may be held to imply a meaning which I do not intend to convey. I refer to the appointment of judges for alpine flowers. It is evident to all devoted growers of herbaceous border flowers—where there is less chance of making a mistake than with alpiners—that in many districts profound dissatisfaction exists with regard to the awards in connection with these flowers. Let me carefully guard myself by saying that I refer to no district in particular, nor do I single out any show; but I know that this statement will be approved by many who, like myself, have "no axe to grind." The truth is that horticulture has, like everything else, become specialised, and it is too much to expect that our judges should be all-round men, who have a critical knowledge of every branch of floriculture, not to speak of horticulture; yet this is what is expected of judges, and they are often called upon to give awards in classes which would require experts. How many of our judges—honourable, intelligent, and highly competent men as most of them are—have the technical knowledge required to enable them to judge a class of alpiners? How many are so intimate with alpiners that they can tell whether some are well or ill-grown, and how many know a rare plant or one excessively difficult to grow?

No one would expect a hardy plantsman to be a qualified man to judge at a Rose or a Chrysanthemum show, nor *vice versa*, is it reasonable to expect a man other than a specialist to judge alpiners (which are far more difficult to judge than border flowers). It is true we have such men, but where we have one such *rara avis* we have twenty or thirty others who, if you speak to them, make no secret of the fact that they would much prefer that such classes should not be submitted to them but handed over to someone who has special knowledge of the plants.

I have stated my case in as temperate a manner as possible, and can only express a hope that in any correspondence which follows we may have a full and free expression of opinion which may lead to some practical end.—S. ARNOTT.

#### MR. WILLIAM HENRY PROTHEROE.

WE are privileged by the courtesy of the comparatively new weekly paper *London*, which is making its way in the City and surroundings, to publish the excellent portrait of a gentleman who is widely known and respected in the horticultural world, and to make the following extract concerning him.

"Of the many thousands who, on business or pleasure intent, crowd hourly along that busy City thoroughfare, Cheapside, how few are aware that, down a quiet passage, about midway between 'Sir John's' clock and the top of Queen Street, they can, almost every day of the year if so disposed, regale their organs of sight and smell with the lovely forms and exquisite fragrance of those weird yet beautiful tropical products known as Orchids. Here, day after day, only a few steps from one of the busiest and most bustling streets of the Metropolis, is to be found a veritable Temple of Flora, glowing with Nature's most brilliant colours, and fragrant with her choicest perfumes, having for its high priest the very pleasant personality whose form and features are depicted on this page. It is concerning this floral hierarch, known among his fellow citizens and throughout the horticultural world as William Henry Protheroe, that we purpose telling the readers of *London* somewhat to-day. Mr. W. H. Protheroe is an instance of hereditary predilections, for his father was the originator of that special combination of aptitudes of which the product is the horticultural auctioneer.

"After passing through a course of private tuition, the classic portion of which enabled him to articulate with fluency and ease those polysyllabic appellations with which the scientific botanist delights 'to paint the Lily and add a perfume to the Violet,' the younger Protheroe was, at the age of sixteen, sent to complete his technical education at the Government Horticultural College at Ghent. Thence, after a lapse of three years, he returned to his native soil, bringing with him his diploma and the highest honours his foreign *alma mater* could bestow.

"Shortly after his return he took the first step in the career which

he has since so successfully pursued, commencing with a six-days sale of nursery stock at Chester, and upon the retirement of his father, after forty years of active business life, he founded, in conjunction with Mr. G. Morris, one of his present partners, the now well-known firm of Protheroe & Morris. Very soon the necessity of obtaining spacious premises for the daily exhibition and sale of horticultural produce became pressing, and ultimately, some ten years ago, the firm settled down in the commodious quarters at Nos. 67 and 68, Cheapside, which they now occupy. This occupation was inaugurated by a sale of imported Orchids, the result proving that the success of the new experiment was assured. Next followed the institution of Dutch bulb sales, which have become so popular that the extraordinary quantity of an average of 15 tons per week passed under the hammer during last season, with the certain prospect that even this record will be beaten later on.

"As before mentioned, Orchids are sold here all the year round, and, inasmuch as the imported Orchid on its arrival is far from being a thing of beauty, presenting to the uneducated eye a decided similarity to a partly decayed Cabbage stalk, it very wisely occurred to Mr. Protheroe to introduce at his sales, by way of object lessons, a number of these plants in the full glory of their bloom, thereby giving to the uninitiated a practical illustration of the remarkable types of beauty that could be obtained from such apparently unpromising

FIG. 77.—MR. WILLIAM HENRY PROTHEROE.

materials. By this happy thought many persons who otherwise would probably never have turned their attention to the subject, became interested, made purchases, and are now the proud possessors of valuable collections.

"One feature which cannot fail to strike the visitor for the first time to one of these sales is the quiet conversational tone which prevails and the evident feeling of thorough good understanding which exists between the auctioneer and his company. Questions are freely asked and courteously answered, opinions mooted and views exchanged with an utter absence of the conventional 'rostrum' style, and with pronounced advantage to such intending purchasers as do not happen to be possessed of any considerable stock of special knowledge. Mr. Protheroe, who is always willing to enlighten inquiring minds, recently expressed an opinion that although there is a falling off in the price of the commoner class of Orchids, fine varieties and rare hybrids would find as eager buyers to-day as formerly. In reply to a further query he stated that the highest prices obtained at any sale ever held was at Downside, Leatherhead, when Mr. William Lee sold off his fine collection in 1887. The first two days' sale contained exactly 500 plants, and the amount realised was £6000, the highest price obtained for a single plant being £326 10s. for a *Cypripedium Stonei platytanum*, which had been purchased two years previously for £60, and which Mr. Protheroe thinks would now bring over £500 if offered for sale. Mr. Protheroe confines himself exclusively to the horticultural branch of the business, leaving to his four partners the land agency and other important departments.

"Being still on the right side of fifty, with plenty of health and energy, the subject of this sketch is likely to be heard of for many years to come in connection with his favourite pursuit."

#### ONCIDIUM LONGIPES.

THIS is a pretty little species of neat growth. The short flower spike is produced from the top of the advancing growth, and bears three or four flowers. The sepals and petals are brown tipped with yellow, the crest and labellum very prominent, bright yellow with occasionally a dark blotch. It should be grown in shallow pots or pans, and kept well up to the light in the Cattleya house.

#### ODONTOGLOSSUM REICHENHEIMI.

This species appears to be getting more common in collections, and is very easily grown. In habit it resembles *Oncidium tigrinum*. The flower spike is erect, branching, and bears a profusion of flowers, which last a long while in perfection. The sepals and petals are recurved, keeled, dark brown, spotted and barred with yellow or greenish white, and sometimes tipped with pure white. The labellum is bright rose, fading to nearly white at the edge. It requires plenty of water while growing and should be kept in the coolest house.

#### DENDROBIUMS.

There are few Orchids which give greater pleasure in return for the trouble bestowed on their culture than Dendrobiums, and as the most beautiful species in the genus are also cheap, it is no wonder they are so popular. The colours range from pure white through many shades of yellow, pink, and purple, and the size and shape of the flowers show considerable variation. Dendrobiums may be divided into three sections—viz, 1, Deciduous, or those which flower on the bare well-ripened bulbs of the previous year's growth; 2, Evergreen, which retain their foliage year by year and flower in the same manner as the deciduous species; and 3, a number of species, such as *D. bigibbum*, *D. Cambridgeanum*, *D. chrysanthum*, which flower on the current year's growth, generally in the autumn months.

Nearly all Dendrobiums require a strong heat with plenty of sunlight and atmospheric moisture while growing, the object being to get the growths finished while there is plenty of sun to ripen them. Strong growing species, such as *D. thyrsiflorum* and *D. speciosum* among the evergreen kinds, and *D. Wardianum*, *D. Pierardi*, and *D. macrophyllum* among those that are deciduous, are greatly benefited by a fortnight's exposure to the open air in August if the growths are "fully made up," this treatment thoroughly hardening and ripening the pseudo-bulbs and laying the foundation for a splendid show of bloom in spring. The deciduous species require little or no water after the leaves have fallen until they show signs of activity in the spring, and a minimum temperature of 40° to 45° is quite high enough for them during the winter months. The evergreen species should, however, be carefully watered all through the winter, and the bulbs must not be allowed to shrivel. The temperature for these ought never to fall below 50°, and if kept a few degrees higher so much the better, but anything approaching excitement must be avoided.

The roots of different species require consideration as to the description of compost best suited to their requirements. Those that are small and seem inclined to grow in a mass should have a little pot, and the compost used in a comparatively fine condition, while those with larger roots which seem more inclined to ramble will be better in slightly larger pots, the compost also being made rougher. Good peat fibre and sphagnum should form the basis of the compost, and the larger the roots the greater the proportion of moss. Good drainage is essential in all cases, and this is secured by filling the pots two-thirds full of crocks and keeping the plants well above the rims. The best time to pot the spring blooming kinds is directly the flowers are over, and the autumn flowering species when they commence to grow.—H. RICHARDS.

#### SHOW PANSIES AND THEIR EARLY HISTORY.

IN the *Journal* of the 25th inst. Mr. Alexander Sweet in his interesting communication is unintentionally misleading, and I think he cannot have seen Mr. James Simkins's book on "The Pansy and How to Grow It," published in 1889, in which are coloured illustrations of our Show Pansies of sixty years ago, and also the early history of the Show and Fancy Pansy written by me at Mr. Simkins's request. I should be sorry to take from Scotland the honour, claimed by Mr. Sweet, of its being a Scotchman who raised the first varieties from the old *Viola tricolor*,

but I am able to say with certainty who was the father (if I may so term it) of the Pansy, and to name the date of its first being taken in hand.

The following extract is from Mr. Simkins's book: "I have (writes an old florist under the signature of 'Dahl') been an amateur for more than fifty years, and can well remember the introduction of the Heartsease, which, though a native of Britain, was never cultivated in order to render it a florists' flower until taken in hand by Mr. Thompson, of Iwer, Bucks, and by him brought into cultivation, and from his original stock have all the beautiful varieties of this flower been produced." He wrote this in 1863.

Mr. Thompson was gardener to the late Lord Gambier, who resided at Iwer, near Uxbridge, and in 1813 or 1814 Lord Gambier brought him a few plants collected in the fields near his mansion. They were the yellow and white wild variety, and Lord Gambier requested him to cultivate these plants. Having done so it was soon discovered that a great improvement was effected. In three or four years many seedlings had been raised, and one which took Lord Gambier's fancy was named Lady Gambier, another George the IV., and a third was named Ajax. The first seedling which showed improved form was named Thompson's King, at that time the only marking about the eye of the improved forms were a few dark lines.

In Harrison's "Floricultural Cabinet," published about 1830 or so, for I have not the volume at hand to refer to, the names of about seventy-five varieties are given, all raised in England, and in a later catalogue of the year 1844 102 varieties are named, raised by the then famous growers, Widnal of Cambridge, Brown of Slough, Thompson, and others, all of English origin excepting three varieties raised by the late Mr. Handasyde of Musselburgh, and these seem to be the first varieties sent out from Scotland. I knew Mr. Thompson and Mr. Handasyde also, and about this period (1840 and onwards) Messrs. Mountjoy of Ealing, Bragg of Slough, Hale of Uxbridge, and others were raising fine improved forms. I must refer those who wish for further information to my paper on the Early History of the Pansy in Mr. Simkins's book. I was anxious that my knowledge as one of the oldest Pansy growers still living should be recorded for the rising generation, and such a record had not been hitherto written.

The late Mr. Charles Turner of Slough was for many years a most successful exhibitor and grower, and sent out many of the very fine varieties raised by Hall and others, and very old Pansy men still have pleasant memories of the superb batches sent out by Mr. Turner in 1854 and 1856, consisting of Admiral Napier, Constellation, Crimson Perfection, Perfection, Sir Walter Scott, Monarch, Emperor, and that grand variety "Charles Turner." What an impetus these varieties gave to the Pansy! I was at that period travelling for the late Mr. Charles Turner, and my orders in Scotland for them were very heavy. About the year 1854 the firm of Messrs. Syme & Middlemas of Glasgow sent out a beautiful refined dark self named Rebecca, and Messrs. Downie and Laird sent out Duchess of Wellington. Amongst the foremost trade growers of these flowers in those days were Messrs. Downie & Laird, Dicksons & Co., Handasyde, Dicksons and Sons, Austin & McAslan, Paton & Small, White & Sinclair, Paul of Paisley, and many others whom I knew, and the Pansy was then so well taken in hand by the amateurs as well as trade growers as to make it the national flower of Scotland.

Our Scottish friends have a more congenial climate for the Pansy than the Southrons, and the late Mr. C. Turner had to give up the Pansy because it gave him up. The southern heat and dryness tells terribly upon these plants, and it is in consequence of this and not from any lack of interest in the Pansy that so few fine varieties are sent out from the South, and the cultivation of the Show section is indeed small.

What an interesting history of the veterans who have passed away could have been written such as that penned by Mr. Sweet in your last issue, and would be most welcome reading to our younger florists. At our recent Midland Counties Pansy Society's Exhibition at Tamworth there was a hearty shaking of hands with old Scottish friends, Lister, Campbell, Irvin, and Smelling, who brought many superb blooms. Other older growers were there and a host of younger men who have their hearts in their work. Truly the Pansy and its lovely sister the bedding Violas are now in the ascendant, and may they long continue so. To some of us the days of further enjoyment of them are short, and we leave as a legacy to them a continuation of our work and our hearty good wishes.—WILLIAM DEAN, *Sparkhill, Birmingham*.

#### FLOWERING TREES AND SHRUBS.

ARE the claims of flowering trees and shrubs to recognition sufficiently admitted by owners of gardens and pleasure grounds? Are the different kinds so well known and so generally planted as is desirable? It is doubtful if affirmative answers can be given to these questions; yet it will be difficult for anyone to deny that at no time are pleasure grounds more beautiful than when the following and other kinds of trees and shrubs are flowering in them.

**EXOCHORDA GRANDIFLORA.**—How seldom do we find this hardy deciduous flowering shrub in private gardens, and yet it is one of the most handsome of all that belongs to this section of spring blooming plants. By some it is called *Spiræa grandiflora*, or Pearl Bush. It is a native of North China. Its culture is very easy, growing freely in any ordinary garden soil, and in that which is retentive it specially revels.

The only point about its culture that is absolutely necessary is that a position exposed to the sun must be chosen, so that the wood will become matured. It is from the previous year's shoots that its pure white blossoms are produced in elegantly formed racemes.

**PERSIAN LILACS.**—For freedom in flowering and a graceful appearance when in bloom the Persian Lilac is to be recommended. The peculiar shade of colour, too, is always appreciated, and as a shrubby plant this *Syringa* should receive more attention than it now has from planters, as variety is thus added. The perfume, however, is not nearly so pleasing as that from the more common *S. vulgaris* and its white form.

**LONICERA TATARICA.**—This, the Tartarian Honeysuckle, introduced as far back as 1752, is annually one of the most free-flowering deciduous shrubs we have, and still it is far from being common. As to soil or situation, it is not at all particular. We have a large bush growing in a western aspect, and not too far away from overhanging trees, still its rose-coloured buds and blush-white expanded blossoms are freely produced.—E. M.

**THE JUDAS TREE** (*Cercis siliquastrum*).—How rarely do we see this quaint-looking shrub in gardens! The curious manner in which the blossoms thrust themselves, as it were, out of the bark of the branches, large or small, renders it a distinct novelty. In spring it is smothered with its purple blossoms, and makes quite a brave show amongst other things in the shrubbery. Later on its foliage, when fully developed, is most pleasing.

**THE SIBERIAN CRAB** (*Pyrus Malus baccata*).—We have a very fine specimen of this *Pyrus* standing on the lawn; its lower boughs sweep the grass beneath. Nothing in the whole garden is more highly prized than this tree when in flower or laden with its golden-coloured fruit in the autumn. Perhaps the tree is in its brightest dress when half of the blooms are expanded, the remainder in bud; the rosy tint of the latter gives variety and a charming contrast to the fully expanded blooms, which are pure white. It is necessary to keep a sharp look out for the bullfinches in the early spring; they are very partial to the buds the moment the latter show signs of vitality. It is hardly necessary to say that if the birds are allowed to have their own way for a few days the beauty of the tree and the crop of fruit are much depreciated.

**GENISTA PRÆCOX.**—This is deserving of much more attention than it receives in the shrubbery or indeed elsewhere in many gardens. For freedom of flower and gracefulness of habit I know of no more attractive shrub for flowering in April. Planted so that its branches can hang over the edge of a pond, and if among rocks so much the better, seems to be the most suitable site for this Broom. The only objectionable point at all is the disagreeable odour emitted from its flowers; especially is this noticeable in a room if by chance any should be cut.

**THE SCOTCH LABURNUM** (*Cytisus alpinus*).—No one I think can dispute the superiority of this variety over all other trees when seen in open places. The chain-like blooms of this variety are of greater length than any other, and the foliage is more profuse and of a deeper tint of green, setting off the rich yellow of the flowers so much better I think than the common kind, which is rightly characterised as "all bloom."

**BERBERIS VULGARIS.**—Although this *Berberis* is looked upon as a common kind it is well worthy of a place where space can be found for its branches to grow in an all-round manner, when they assume that semi-weeping character which renders this species so striking an object, with its pale yellow blossoms depending from underneath the branches. Even the smallest twigs are heavily laden. We have it growing in an isolated position over a base of closely cut common Laurel; this latter provides quite a good contrast to the *Berberis*.

**SPIRÆA PRUNIFOLIA FL.-PL.**—This is one of the best of the shrubby members of this family, not only on account of the purity of its small rosette like blossoms, but for the length of time that they remain in a fresh condition upon the plant. This variety does not require the space that some do, being more compact, and of less vigour.—E. M.

### THE LARCH DISEASE.

LITTLE wonder this disease excites attention among planters, because it threatens the partial if not total extinction of the most profitable timber tree in Britain; not altogether because the trees become diseased and worthless, but also because landowners hesitate to plant it for fear of the disease. Larch timber gets scarcer every day, and in many localities there are now no saleable Larch and few young plantations.

The late Mr. Macgregor, forester to the Duke of Athole, in his examination by the Select Committee on Forestry a few years back, said the Larch "was not now growing in any place hardly in Scotland," and that there was nothing to come into competition with Larch if it would grow as it did eighty years ago. Since then, when on a visit to Mr. Macgregor at Dunkeld, he told me he believed late frosts to be the originating cause of the disease, and this leads me to ask if any of your readers have ever considered how much the Larch disease resembles "gumming" in the Peach tree, making allowance for the different habits of the two species. Gumming is as destructive as the Larch disease, and it is many years since Robert Thompson of Chiswick wrote

that when it pervaded a tree to any serious extent that tree was done for. Now we know pretty well what causes gumming. So far as I am aware it is never troublesome where the trees can ripen their wood well, as, for example, in a heated glass house; but outdoors, in a rich soil where the growths are rank and immature, and are cut hard back or wounded from any cause, gumming will appear. Gross growth affected by anything which seems to check the circulation is almost sure to be followed by gumming. But after all, the gum appears to be one of the constituents of the tree, and it is only its abnormal development which constitutes the disease. So in the Larch. Those ulcerated swellings on the stem look more like gummy or resinous eruptions than anything else. Authorities on the Pinaceæ—Senilis, for example—assert that the Larch in its native habitat, when in the best of health, shows symptoms of the disease "circulating through the entire system of the plant," and that the altered conditions of climate, situation, and culture develop the disease as seen in this country. The curious thing about it is that it is the younger plantations that suffer most, while old plantations escape almost entirely. How is it that climatic conditions affect the one and not the other? The soil theory will not do, because the disease is found on all soils.

Are there diseased strains of Larch? It would be interesting to trace the source of some diseased plantations. A few years ago I valued the woods on an estate in the North of England, and on one strip of bank on the river side a plantation of Larch about thirty-five years old was free from disease, and in a plantation on the same bank and soil, planted perhaps twenty years later, the trees were so badly diseased as to be almost worthless. One fact is pretty well established. As soon as home-grown Larch seed could be got it was preferred, and has been steadily recommended by growers (on what reasonable grounds I would like to discover), and since then the disease may be said to have originated and spread. I would never plant Larch from home-saved seed if I could get foreign, and my reason for this is the superior conditions of existing plantations on all sorts of situations, and which must have been produced from foreign seed.—J. S., W.

### DEATH OF MR. SAMUEL BARLOW.

WE regret to announce the death of Mr. Samuel Barlow of Stakehill, Castleton, near Rochdale, which took place on Sunday morning last at his residence at twenty minutes to eight o'clock. The following account of the career of the deceased gentleman, who was so widely known and respected in the floral world, has been sent to us, and it will be observed that the position he attained was the result of his perseverance, industry, and business aptitude.

Mr. Barlow was born in 1825, and received the rudiments of education, for the completion of which he was so much indebted to his own perseverance and natural love of study, at the village school of Woodhouses near to Daisy Nook. At an early age he commenced to work in the bleachworks of Messrs. Otho Hulme & Sons, Medlock Vale, his father being at that time manager. Working all day and spending his evenings at the night class of Woodhouses, the boy assiduously prepared himself for the busy and useful career which was in store for him. From Medlock Vale the family removed, at the end of 1839, to Salford, where Mr. Barlow's father had taken the place of manager of the bleaching department of the Adelphi Print Works, then in the occupation of Messrs. Gisborne & Wilson. Here Mr. Barlow's abilities began to display themselves to some purpose. Being sent into the colour making department at the Adelphi Works, and being apprenticed to that business, such was the natural taste he evinced for the work, that before the term of his apprenticeship had expired he had charge of the department, and was appointed foreman colour-maker and assistant manager, which position he held until the dissolution of the firm. In 1847 the father accepted the appointment of manager of the bleachworks at Stakehill, then occupied by Messrs. Heald, Wilson & Co., and the son, then being out of work, went with him to assist at the starting of the new management, intending to remain only until he found a suitable opportunity of pursuing his own employment. He soon found congenial employment, however, at Stakehill, which has ever since been his residence. On the death of his father in 1855 Mr. Barlow became sole manager of the works, which in the interval had been considerably extended.

In 1861 Messrs. Heald, Wilson, & Co. gave up business, and then Mr. Barlow, in conjunction with partners, became proprietor of Stakehill Bleachworks, the business of which has ever since been conducted under the style of Samuel Barlow & Co. The practical scientific knowledge and the ingenuity of the principal partner resulted in the introduction at Stakehill of certain improvements in the mechanical process, which proved so useful that the premises had to be considerably enlarged, with corresponding material advantages to the firm. In addition to his manifold business duties, Mr. Barlow took a great interest in public affairs, and was a Justice of the Peace and a County Alderman. Mr. Barlow at the time of his death was Mayor of Middleton. He was also a Director of the Winterbottom Book Cloth Company Limited, and a past President and existing Vice-President of the Manchester Arts Club. He was a great florist, and there can be no doubt that some of the greatest pleasures of his life were associated with horticulture. Mr. Barlow often acted as a judge at the shows connected with the Manchester Royal Botanical Society. His botanical knowledge was very considerable. He also possessed many amiable as well as business qualities, and was so much respected that the highest civic honours were conferred upon him by those among whom he lived, and who were, perhaps, the best able to judge of his worth.

**EVENTS OF THE WEEK.**—Horticultural events of special interest are not particularly numerous in the metropolis during the ensuing week. As mentioned below, the Committees of the Royal Horticultural Society will meet at the Drill Hall, James Street, S.W., on Tuesday, June 6th, and the first exhibition of the London Pansy Society will also be held on that day and at the same place.

— **THE WEATHER IN LONDON.**—Bright sunny days have prevailed during the past week. On Monday afternoon, however, occasional showers occurred, and during the night a refreshing rain fell. Tuesday was fine, and the same may be said of Wednesday, the weather appearing settled as we are going to press.

— **WEATHER IN THE NORTH.**—The weather has been cooler generally during the past week. Friday and Saturday last were two of the finest days we have had. Sunday was rather cold in the afternoon, and a good deal of rain fell during the night and on the forenoon of Monday. Tuesday morning was fine, rather cool, but sunny and pleasant. Lowest night temperature 43° during week.—B. D., *S. Perthshire*.

— **A ROSE SHOW AT EARL'S COURT.**—We are informed that arrangements have been made to hold a supplementary show of Roses at the Gardening and Forestry Exhibition, Earl's Court, on June 14th and 15th. Liberal prizes are offered, which should bring forth a keen competition in the seventeen classes provided.

— **ROYAL HORTICULTURAL SOCIETY.**—The next meeting of the Royal Horticultural Society will take place in the Drill Hall, James Street, Victoria Street, Westminster, on Tuesday, June 6th. Besides the usual display of plants, flowers, fruits, &c., the members of the London Pansy and Violet Society will compete for prizes offered in the schedule. At three o'clock Sir John Llewelyn, Bart., will lecture on "Hardy Rhododendrons and Azaleas."

— **THE TEMPLE SHOW.**—As our pages are being prepared for the machine we receive the following official statement:—"There was no doubt as to the Royal Horticultural Society's Temple Show being a great success from an exhibition point of view, and it is an agreeable task to be able to record the fact that it was also a financial success. The receipts exceed those of any previous year, and this is remarkable, considering the great number of people who were 'out of town' on their Whitsun holidays, and that the Show had to stand on its own merits, without having had the advantage of a royal duke to perform the opening ceremony."

— **CAN PLANTS SEE?**—Darwin gave it as his opinion that some of them can, and according to the "Daily News" an Indian botanist relates some curious incidents which tend to verify the belief. Observing one morning that the tendrils of a *Convolvulus* on his verandah had decidedly leaned over towards his leg as he lay in an attitude of repose, he tried a series of experiments with a long pole, placing it in such a position that the leaves would have to turn away from the light in order to reach it. In every case he found that the tendrils set themselves visibly towards the pole, and in a few hours had twined themselves closely round it.

— **ELECTRIC LIGHT AND PLANT STRUCTURE.**—Mr. G. Bonnier has conducted some interesting experiments to ascertain how the structure of herbaceous plants is influenced by exposure to the electric light. He finds, according to the "Comptes Rendus," that direct electric light is prejudicial to the normal development of the tissues on account of its ultra-violet rays. Generally, when considerable development, accompanied by intensification of the green colouration, is caused by continuous electric light, in plants growing under glass shades that intercept excess of ultra-violet radiation, at first high differentiation occurs in the structure of the organs; but an intense light, prolonged unchanged for months, causes remarkable modifications of structure in the various tissues of such new organs as are capable of adapting themselves to the illumination. Less differentiation then takes place in these organs, though they are always rich in chlorophyll.

— **BOTANICAL APPOINTMENT.**—We understand that Dr. N. Wills has been appointed ordinary Professor of Botany at the University and Director of the Botanic Gardens at Christiana.

— **THE JAPANESE GARDEN** is said to be a decided feature at the World's Fair at Chicago. It is a complete miniature garden, with walks and bridges, and filled with the curiously trained plants for which Japan is noted.

— **"JOHNSON'S GARDENERS' DICTIONARY."**—The fourth part of the new edition of this well known dictionary has been issued. As in previous instalments the work is well done, and plants from *Feronia* to *Indigofera* are described.

— **RICHMOND HORTICULTURAL SOCIETY.**—The nineteenth annual summer Exhibition of this Society will be held in the Old Deer Park, Richmond, on Wednesday, June 28th. A liberal schedule has been prepared, and a good Show no doubt will result.

— **SCOTTISH POTATOES IN AMERICA.**—It is reported that large quantities of Scottish Potatoes are being shipped weekly from the Clyde to United States ports. Two steamers for New York recently took out 944 tons, which are valued at £3620.

— **BRISTOL AND WEST OF ENGLAND CARNATION SOCIETY.**—Mr. F. W. Baker, the Honorary Secretary of the new Society, referred to on page 416 last week, informs us that arrangements have been made to hold the first Show in the Clifton Zoological Gardens on the 19th of July. The High Sheriff of Bristol is President this year. Schedules, we are informed, will be out in a few days.

— **A CHILDREN'S FLORAL FÊTE.**—A Floral Fête for children will be held under the auspices of the Royal Botanic Society, at the Gardens, Regent's Park, on Wednesday, June 21st. Prizes are offered for single and double mail carts, goat chaises, tricycles, ponies, and sedan chairs decorated with flowers. Special prizes will also be given for groups of plants and flowers, Ferns, hanging baskets, and window boxes.

— **SMALL HOLDINGS NEAR LONDON.**—Under the auspices of the Small Holdings Committee of the London County Council, thirty-six plots have been let on the Millmeads, some low-lying land around the Abbey Mills Pumping Station, where forty-two further plots will shortly be ready for letting. Some land at Plumstead, Charlton, and Millwall will shortly be secured for the same purpose, and the Committee further propose to temporarily use portions of Hackney Marshes for allotments, at the same time raising the level of the marshes, which are at present subject to flooding.

— **FLOWERING SHRUBS AT LAMPORT HALL.**—I was very much interested in reading the account in your last issue (page 418) of the flowering shrubs at Lamport Hall. I can fully endorse Mr. McKinlay's statement respecting the same. I was for five years foreman in the Hall gardens and had good opportunities of observing the beautiful trees and shrubs which adorn the plantations. Certainly they are worth going a long distance to see. Visitors to Lamport should also inspect the rockery, where they will find objects of interest to repay them for the journey.—G. FREEMAN, *Akeley Wood House, Buckingham*.

— **EVOLUTION IN THE FLOWER.**—At a recent meeting of the Ealing Microscopical and Natural History Society, the Rev. G. Henslow presiding, Mr. J. N. Green, Professor of Botany of the Pharmaceutical Society, London, delivered a lecture on "Evolution in the Flower." The lecturer, described the structure of a typical flower, and dealt in an interesting manner with the processes under which fertilisation or pollination of certain flowers is effected by means of pollen involuntarily conveyed from one flower to another flower of the same species by insects (flies and bees) which visit the flowers for the purpose of extracting honey from them.

— **THE TREE LUPIN (*LUPINUS ABBOREUS*)** is at present very fine; a large plant of the yellow variety, over 6 feet high, having more than 100 spikes in bloom. The light yellow flowers are very pleasing at this period, and, as the plant continues in flower for a month or two, it is very acceptable from its distinct appearance. The lilac form is no less beautiful, but is less valuable where the varieties of *L. polyphyllus*, *L. nootkatensis*, or other blue kinds are grown. The yellow variety associates well also with the Delphiniums, which will be in flower before it is over. The Tree Lupins are short-lived generally, but grow readily from seed, and may be increased by cuttings in the summer.—S. ARNOTT.

## — FARNHAM AMATEUR ROSE AND HORTICULTURAL ASSOCIATION.

—This Show will be held on July 5th, when, besides other open prizes, a prize of £5 will be given for the best twenty-four Hybrid Perpetual Roses, open to all amateur and professional growers. Mr. Coldham C. Knight is the Honorary Secretary.

— DEATH OF MR. J. B. WEBSTER.—We regret to learn of the death of Mr. J. B. Webster, late forester to Her Majesty at Balmoral Castle, and for many years estate manager to Sir William Verner Churchill, Vennersbridge, Ireland. Mr. Webster was seventy-four years of age, and died recently at Glasgow.

— SHEFFIELD NATURALISTS' CLUB.—Under the auspices of this Club a lecture on the "Development of Leaves" was delivered recently in the Montgomery Hall by Mr. William White. The chair was taken by Mr. Howarth. The lecturer commenced by describing the different forms of leaves—round, triangular, arrow, and spear-shaped. He gave some interesting information regarding the progression of the development, and stated that some leaves which were almost round in their first stages became jagged in their ultimate forms.

— THE DEATH OF MRS. STEEL OF HEATHERSLAW.—Readers of the *Journal* will be familiar with Mr. George Steel's name as a writer in our columns on Violas, Pansies, and Hollyhocks, and will share our regret at the sudden death of Mrs. Steel on the 13th ult. at the early age of thirty-six. She was as enthusiastic as her husband in the raising of seedling Pansies and Violas, and Heatherslaw is becoming famous for the charming varieties, especially of the *Violetta* section of the latter. All florists will join in very sincere sympathy with Mr. Steel in his sad bereavement.

— A SAVAGE CORRESPONDENT.—It quite makes me savage when I read in the *Journal* of such good rains in various parts of the country. We have had scarcely any for three months. There is little grass and no haymaking about here. Strawberries will be almost a failure. Apples a fair crop, but falling. Pears short, so many having already fallen. Cherries only skins and stones. Plums very short, and the trees covered with insects.—J. W. L., *Erith*. [We trust Erith had a share of the welcome shower that fell around London on Monday night, and that our correspondent is now more docile in consequence.]

— THE ORDINARY QUAMASH (*Camassia esculenta*) is doing unusually well this year, the pleasing purple-blue flowers with yellow anthers being very plentifully produced on long spikes. Unfortunately it lasts in flower for a very short time, and if grown in a sunny position in light soil the flowers rapidly pass away. I thus find it better to grow it in a position where it only receives a little sun in the morning and where the soil is fairly moist. The white variety, *C. esculenta alba*, which I also grow here is very inferior to the type in general effect, the flowers being a dingy white, entirely wanting in purity.—S. ARNOTT.

— SUTTON'S EARLY GEM CARROT.—Mr. H. Dunkin, Warwick Castle, writes:—This is a splendid early variety for open-air culture. The roots come quickly to maturity, are tender, and of excellent quality. On March the 8th I sowed a dozen rows in a warm border, and on May the 10th began to pull young Carrots for use. Since that date enough for a good dish have been obtained daily. I have not tried this variety side by side with Early Nantes, but some of the latter sown ten days later than Early Gem are very much later, and do not promise to supply roots fit for use for at least another fortnight. The position they occupy, however, is not such a warm one. Perhaps other readers of the *Journal* who have tried the two varieties under precisely the same conditions will record their experience as to the comparative earliness of either.

— ROYAL BOTANIC SOCIETY.—The third and concluding lecture upon Ferns was given last week at the gardens by Professor J. W. Groves, F.L.S. On the previous Friday the lecturer had dealt with their formation and development, devoting the present one to a consideration of the points in common existing between Ferns and flowering plants, or, as he preferred to call it, between spore-bearing and seed-bearing plants. So far as the structure of roots, stems, and leaves were concerned, no true differences were found; it was only when we come to deal with the flower and seeds on the one hand, and the spore and its peculiar development on the other, that vital difference appeared. If, however, we took the spores of the Ferns as equivalent to the pollen grains of flowering plants, a correspondence in structure and functions was to be seen, and, with one or two exceptions, could be traced throughout their subsequent development.

— EARLY RIVERS NECTARINE.—Mr. T. F. Rivers has sent us ripe specimens of this new Nectarine. The quality of the fruit is equal to its fine appearance. Had it been named for indicating flavour it might not inappropriately have been called the Champagne Nectarine, so sprightly is its bountiful juice, and distinct and agreeable its aroma. Early Rivers is a beautiful Nectarine, not to be lost sight of by planters in and out doors.

— ARNICA MONTANA.—Referring to Mr. Divers' note (page 415) I fear this cannot usually be considered a long-lived plant. It has never been a success with me, which I attribute to the dryness of my soil and the want of moisture. The plant requires a rather peaty soil, and a plentiful supply of moisture. I cannot say that I have met with any good specimens anywhere, and for many years it has had the reputation of being a bad "doer" in cultivation.—S. ARNOTT.

— AN EDIBLE THISTLE.—In the search for improved vegetables, says "Meehan's Monthly," the Rocky Mountain Thistle should not be forgotten. It rolls up its young leaves after the fashion of a Cabbage Lettuce, and was food for Indians who, as Dr. Coues has determined, called it Shanataque. The writer of this paragraph has collected them in Colorado as large as small Cabbages. They ought to be as good as an Artichoke, which is the flower head of an ally of the Thistle. Dr. Gray named it *Cnicus edulis*.

— BAMBOOS AT KEW.—A new garden was made in the early part of 1892 in the wood near the Rhododendron Dell, and now accommodates an extensive collection of Bamboos. The place was in past times a gravel pit, and by the removal of many hundreds of loads of sand and gravel it has been considerably enlarged, and is now a pretty, sheltered hollow. It is intended eventually, says the "*Kew Guild Journal*," to concentrate here all the larger-growing hardy Monocotyledonous plants.

— THE HELIANTHEMUMS or SUN ROSES, writes Mr. S. Arnett, are very delightful at present, and it is a matter of surprise that they are so seldom seen. It is true the flowers are extremely fugacious, but then they are succeeded by others day after day for a considerable time, so that a good-sized bush is in the mornings of fine days covered with the small saucer-shaped flowers of various shades of pink, red, white, and yellow. The plants like a sunny position and a dry soil, but they should not be allowed to become too dry, as this would shorten the blooming period. They are very readily raised from seed, and a small packet will supply plants enough and to spare. Old plants do not remove satisfactorily. They are hardier than the Rock Cistus and flower earlier.

— A JUBILEE CELEBRATION.—On Saturday last the staff and some private friends of Messrs. Hurst & Son, the great wholesale seedsmen of Houndsditch, celebrated the jubilee of the foundation of the house in 1843. Upwards of a hundred of the former and a goodly number of the latter assembled at the Paddington Station of the Great Western Railway, where saloon carriages were provided to convey them to Slough, led by Mr. N. N. Sherwood, the head of the house. Arrived at Slough an ample lunch was provided for them at the Railway Hotel, and thereafter the whole party entered the breaks and carriages specially provided for their use, and proceeded according to their fancy, some for a drive to Virginia Water, others to view home farms or the garden. In the evening the whole party assembled at the hotel and sat down to a sumptuous dinner provided by the highly respected head of the establishment.

— THE KEW ARBORETUM.—According to the "*Journal of the Kew Guild*" the Arboretum continues to grow in extent and interest, and attracts considerable attention from horticulturists. In spite of the evil effects of London fog, the collection of Coniferae is now a very fine one and comprises many handsome specimens. Deciduous trees and shrubs are also becoming more and more interesting, and as the fogs and smoke of winter do not appreciably damage them, they are likely to become much more extensively used for gardens in the neighbourhood of large towns than they are now. The Curator, Mr. Nicholson, is preparing a catalogue of all the hardy ligneous plants cultivated at Kew, which will no doubt be published in some form so that all who are interested in trees and shrubs will be able to obtain it. This catalogue will reveal a wealth of material available for outdoor gardening of which few people have any idea. Anyone who has made a study of the collections grown outside at Kew will agree that in English gardening generally there is a want of variety among the trees and shrubs used which under the circumstances is deplorable.

— WHAT BECOMES OF THE APHIS IN THE WINTER?—Regarding this question Mr. T. A. Sharpe writes to *Nature* as follows:—"I have spent many weeks this spring closely observing the budding trees, with the object of discovering in what condition of life the aphis spends the winter; as the result of my observations, which were made under the microscope, I believe that the aphidæ during the autumn (or as many of them as have reached the state of reproduction) attach themselves to the stem of the tree, with their young inside them, in much the same way as the female members of the closely allied family coccidæ do. In course of time the mother aphis becomes simply a dried skin serving as a protection to the young. When the warm days of spring come these are developed and easily make their way through the skin and crawl on to the young leaves, there to begin their work of sucking and reproduction."

— PRIMULA SIEBOLDI.—It is only when one comes across plants grown to perfection that their useful and ornamental characteristics can be fully appreciated, and I have never as yet in the neighbourhood of Liverpool seen anything in the way of outdoor flowers to approach two beds of the above *Primula* growing in the garden of Mr. Andrew Lawson of Knowsley. From some small roots received a few years ago he has now two beds containing thousands of plants. The first planted is so full of bloom that not a leaf can be seen, but it was a bed planted early last October which I admired most, for there the pretty pale green leaves formed a striking contrast to the deep rose flowers with their white eyes. To see them at their best the plants must not be overcrowded, or the colour becomes monotonous. Much the finer spikes were to be seen on plants that had been transplanted. The ordinary garden soil mixed with road scrapings and decayed horse manure is the compost they seem to revel in. When the plants are peeping through the ground in the spring a top-dressing of the same soil is given, and they are secure for the summer.—R. P. R.

— WAKEFIELD PAXTON SOCIETY.—At the recent weekly meeting of the members of the above society, Mr. George Hudson, head gardener at Woolley Park, read a paper on "The Rhododendron," which he cultivates very extensively and most successfully. Mr. Hudson dealt with his subject in a thoroughly practical and deeply interesting manner, and his address was attentively listened to and warmly applauded. The essayist clearly explained how to grow the Rhododendron from seed, and said it likes a peaty and abhors a limestone soil, and he recommended growers to pick off the old seed vessels. An interesting discussion followed the reading of the essay, in which Messrs. Brown, W. Hudson, Wilson, and others took part. The room presented an exceedingly bright and most attractive appearance, there being tastefully arranged on the large tables an extensive and very beautiful and varied collection of blooms of the Rhododendron, Iris, Calceolarias, and several other varieties of flowers, all of which had been effectively arranged by Mr. W. Blackburn, the Curator, assisted by Mr. J. G. Brown. The flowers were subsequently disposed of and realised 9s. in aid of the Royal Gardeners' Orphan Fund.

— THE GREATEST RAINFALL IN TWENTY-FOUR HOURS.—In the *Journal of Horticulture* for May 4th, Mr. Clement Wragge of Brisbane, asserts that Queensland has beaten the world's record in the extraordinary amount recorded on February 3rd—viz., 35.7 inches. Commenting on this in *Nature* last week, Mr. E. Douglas Archibald says:—"I am sorry to have to take away such an unenviable palm from Queensland by recalling a fact well known to every Indian meteorologist, that the highest record extant belongs to Chirapunji in the Khasia hills, where on June 14th, 1876, 40.8 inches were recorded in the twenty-four hours. Not only so, but on the 12th 30 inches fell, and in the four days, from the 12th to the 15th inclusive, as much as 102 inches. Of course the effects were not so disastrous in this case, as indeed such a state of things is little removed from the normal at Chirapunji in the early part of June; but I have a very clear recollection of it as I was at Chirapunji on the 12th and 13th, and not far from it on the memorable 14th. The conditions which have occurred in Queensland and the North Island of New Zealand during the last six months have been a remarkable example of persistent abnormals, and though the total number of rational causes may still be wanting to explain everything, one or two were evidently in operation when I was there from October to January, and I am confident that from the empirical law of persistency, coupled with a few rational inferences, a forecast of impending floods could have been made and can be made for the future, much in the same way as the general character of the monsoon can be foretold in India."

— TESTING THE FERTILITY OF LAND.—According to a writer of many years ago, a person in buying a piece of ground for horticultural uses, dissolved a handful of earth from the land in question, in water. After leaving it to settle for several hours, if the water was tasteless the land was considered fit for use. Possibly these old fashioned people only know that some good came from this test, and they may have been laughed at as a set of agricultural "cranks," says "Meehan's Monthly." Since moderns have discovered that the fertility of a soil depends on its power to absorb and retain nutritive matter, the old-time practice is seen to have been a sensible one. The purity of water showed that the land had properly absorbed the fertilising material in the water. A blind man was once laughed at for going to select a farm. On being helped out of the vehicle, he asked that the horse might be led to a bunch of Thistles. He was told there were none. Then he remarked that Docks would do as well. This request they were able to gratify. He subsequently bought the farm. When asked the reason for his "cranky" desires, he replied that Thistles grew on poor land, Docks only on rich soil.

— ARAUCARIA IMBRICATA.—Every old Kewite will remember the large Chilean Pine which until last autumn stood on the lawn near the conservatory. For several years it had been rapidly deteriorating, every winter rendering it more gaunt and unsightly. Latterly, says the "Journal of the Kew Guild," it became too dilapidated to be even picturesque, and so far as the beauty of that part of the garden is concerned nothing was lost when, last autumn, its death necessitated its removal. One cannot help regretting it, however, as a tree of great interest; it was, in fact, an old Kewite with a romantic history. The story of its introduction to Kew is an "oft told tale," which has, moreover, lately gone the round of the daily press, so that the following few particulars of its origin will suffice. In 1792 Archibald Menzies, a navy surgeon and botanist, was dining with the Viceroy of Chili, when at dessert some nuts were brought to table which were quite unknown to him. Of these he kept a few, which he afterwards sowed in a box of soil; they germinated on board ship, and he finally succeeded in bringing five plants home to Kew, which were the first ever seen in this country. Of these, the specimen under notice was one, so that when it died it was exactly 100 years old. It seems to have been much damaged by being used at a fête at Carlton House during the Regency of George IV., hanging lamps having been attached to its branches.

#### NOTES ON THE BERBERIS.

It would be difficult to over-estimate the value of these beautiful hardy flowering shrubs, for they are most useful for outside decoration during the spring. They are extensively cultivated on the pleasure grounds here, and the produce a splendid display. The various species of *Berberis* are adapted for planting in large beds, isolated on the lawn, or placed in conspicuous positions in the foreground on shrubbery borders or in the wild garden. They also present a very striking appearance when placed at intervals along the carriage drives or woodland walks.

When planting *Berberis* it is essential not to place them in too close proximity with other shrubs, for if sufficient space is not allowed them to fully develop it is impossible to see them to advantage. These shrubs are not, as a rule, very fastidious as regards the nature of the soil, but I think a good stiff loamy soil is the most suitable. The soil here is of a very retentive nature, and I never remember seeing them succeed so well as they are doing, especially *B. Darwini* and *B. stenophylla*, every shoot and twig of which being completely covered with bloom.

The species above named are the best and most useful of the whole genus. Though equally desirable they are totally distinct in character, the former being of an upright or erect growing nature, whilst the latter is of a drooping or pendulous habit. *B. empetrifolia* is also a very useful species. This is of a dwarf growing nature, seldom attaining more than 1½ to 2 feet in height. It is adapted for planting on rock-work or in the alpine garden. *B. aquifolium* and *B. repens* are also extensively grown here, being especially valuable on account of their early flowering nature.—G. PARRANT, *Ashby Lodge Gardens, Rugby.*

#### A VISIT TO STUDLEY ROYAL.

A VISIT to Yorkshire and the baronial mansions it contains is always interesting historically, and to all horticulturists there is something instructive and worthy of record. Such was the case I had the pleasure of experiencing recently when I was present with the members of the South Shields and Westoe Burial Board, at the invitation of the Chairman, J. Muir Smith, Esq.

The place selected was Studley Royal, the country residence of the Marquis of Ripon. We first visited Fountains Abbey, which, perhaps, contains some of the finest forest trees in the northern counties, and for

effect as the true work of a landscape garden artist, many writers say, has no equal in this country. The lakes, cascades, and surprise views are most complete and *récherché* in their effectiveness in giving a dominant view of the salient points of the Abbey and the Cathedral at Ripon.

After enjoying these fine woods and woodland natural parterres a hurried visit took us to the gardens. These have recently been placed under the charge of Mr. Fred Kneller, and astonishing zeal and activity he has displayed in the six months he has been there. All the old Vines have been taken out, new ones planted, and new piping in all the vinerias as well as new boilers, three of Green's Municipal Boilers and one vertical one have been employed. The kitchen gardens have also been remodelled and planted with fruit trees. This place will be worth a visit by-and-by when Mr. Kneller has had time to complete and mature all his plans for the practical and general beauty of the grounds.

In front of the mansion and adjoining the Italian garden there are some fine Coniferae—*Thuja borealis*, 40 feet, and a Silver Spruce, 75 feet high, supposed to be the finest in England. There are also a few *Cedrus atlantica*, 80 feet high, planted by the Princess of Wales about twenty-five years ago, and a young *Cedrus Deodara* in 1887 by Mr. W. E. Gladstone; in addition *Abies pinsapo* and *Cupressus Lawsoniana* are scattered about. The flower garden is a pure specimen of the Italian style.—BERNARD COWAN, F.R.H.S.

### AMERICAN ORCHARDING.

"AMERICAN GARDENING" for April contains the following trite remarks on the "growth" of a nurseryman into a large orchardist.

"Forty years and more ago T. C. Maxwell started a nursery upon six acres of land at Geneva, New York. Tree-growing was a new business in those days [in America], and even the few bold spirits who attempted it began cautiously. The little venture of young Maxwell prospered, and he soon associated with him an elder and a younger brother, Henry and Joshua, under the firm name of T. C. Maxwell and Brothers. The young firm soon gained a reputation for energy and reliability, and for thirty years it distributed an enormous quantity [for America] of fruit and ornamental trees throughout the country. But there finally arose a great competition in the nursery business, and prices fell, while the prices for good fruits were rising. Fruit-growing is the natural outcome of tree-growing, and the Maxwells, like scores of others in this interesting Western New York country, graduated from the nursery business into the fruit business. It is marvellous what a hold plant life and fruit culture obtain upon the nurseryman; he never outgrows his love of trees and flowers. And his training in the nursery makes him the most discerning and successful of fruit-raisers, and his influence extends far and wide.

"It is a universal practice in Western New York to raise fruit-tree stock upon new land—soil which has not grown nursery stock before. This arises from the fact that treed land produces short wood, because it is deficient in some of the immediate elements of tree growth; yet the fact that there are thousands of acres of successful orchards in this region upon old nursery lands is proof that the soil still contains sufficient fertility for profitable tree-growing. The excessive growth of nursery stock consumes much of the readily available plant food, but the more unavailable elements are still retained, and give themselves up slowly but continuously to the moderate demands of mature trees. The age of the nursery tree determines its market value, and the greater size must be attained in the given time, but the fruiting tree is measured by its performance rather than by its age. So it comes that soil which is no longer profitable for fruit-tree stock may still make the best of orchard lands."

In this we have an instance of the difference between American and English methods, and it affords the key to the success of the nursery, and points to the reason of the general failure of British orchards. The nursery grounds are broken up deeply, in many cases trenched, and the soil undergoes considerable knocking about and mixing to a good depth in the course of the succession of young trees. Thus the soil manufactures enough food for the young stock, and is left in the finest condition for manufacturing more—sufficient for trees planted at six to twelve times the distance apart. What has supported those number of trees will certainly be made fast enough and quite sufficient for one to get a good grip of the soil and produce fruit profitably at an early age, after which it is only a question of feeding in the right place, at the proper time, with the needful elements. That is why nursery land is suitable for an orchard. True, this system prevails in some instances in fruit plantations, and where it does there is little to choose between American and well-grown English fruit, as both are alike excellent, but the latter is more juicy, and as regards feeding value the better of the two.

But the idea that any description of soil is good enough for fruit trees, and any site suitable, is to build castles in the air, and perish in the effort. Breaking up scrub land, digging holes in poverty stricken soils, and sticking in fruit trees where nothing has grown well hitherto, is the way not to do it. Why cannot we supply the home market, and become exporters instead of importers? Land that has had no more done to it in the way of cultivation than loosening the surface with plough and harrow may grow the surface-rooting Currants, Gooseberries, and Plums, but it is only planting Apples, Cherries, and Pears in pan

soils to gum or canker to death. There are some soils naturally permeable to air and rain for the manufacture of a sufficient supply of the mineral elements, and it is only then necessary to augment the natural resources by artificial supplies, with nitrogenous elements for the essential growth, according to the exigencies of the season and the demands of the crops.

The Maxwells commenced twenty-five years ago with fifty acres set with "Baldwins, Greenings, Spitzenburgs, Red Canadian, and other standard kinds. . . . Twenty-five acres more are devoted to Apple orchards in other places, making a total of seventy-five acres. All these orchards are regularly pruned and manured, and just as regularly sprayed with Paris green and Bordeaux mixture. Even last year, when the early season was exceptionally wet, good results were obtained from the spray, the freedom from leaf blight, and the small amount of scabby and wormy fruit. The largest crop which the fifty-acre orchard has produced is 9000 bushels."

The yield of the American orchard of fifty acres is at the rate of 36 bushels per tree at twenty-five years of age, if the trees are 24 feet apart, and "the trees are singularly uniform in size and shape, and they are ideal types of the high heads and round tops of the Western New York system of Apple-growing"—that is, they are standard trees, and so are the trees of the Northern United States and Canada that supply the choicest Apples to the British markets. In fact, the "setting out" of the lands acquired by the "pilgrim fathers" in America, and the colonists at the Antipodes has been on the same lines as that of their ancestors in England before the Roman invasion. But the orchards of England are a failure; 99 per cent. of those attached to farmssteads produce crab-like, scabby, and wormy fruit, with a singular irregularity in the size and an anomalous shape in the trees, models of what can be produced by fungal and insect pests, starvation, and neglect. Instead of proving, like the Apple orchards of America and the Antipodes, "a safe investment," they have not given a tithe of the results for which the owners have looked, and the reason is they have not been attended to in matters of pruning and cultivation and the keynote of successful practice and the incentive to maintain a place in the struggle for existence. This in a country the richest in soil and with a climate best calculated to produce the juiciest and finest Apples in the world. It is not the soil or the climate that prevent ours being an importing instead of an exporting country in the matter of hardy fruits; but it is in the cultivation—not keeping pace with the most important discoveries of modern horticulture, and striving to meet the requirements of the increased population with produce of a higher using value at a rate within reach, for, sentiment aside, the stomach rules the world, and instead of its being a question of force it is a matter of culture.

All growers of fruit for sale advocate few varieties to be planted. This is no doubt right from a certain standpoint. Half a dozen varieties of Apples noted for great productiveness and constant bearing may continue so for a time, but that will reach its limit, and then it will be found that certain varieties have lost the power to properly fertilise themselves, and they will then cease to bear full and regular crops. This already is the case in America and in the European vineyards—lessened vintages through degeneration, and consequent greater susceptibility to disease. There can be nothing of this where new varieties are constantly being introduced. Mr. Rivers has no difficulty in securing enormous crops of his Early Prolific Plum—it is a total failure in some soils. But is it a question of soil, or incapability of self-fertilisation? The planting in blocks acres of one variety must lead to absolute sterility, or the Darwinian conceptions are positively erroneous. But the trees verify all that Darwin has advanced, and much more; for a block of one variety so isolated as to be beyond the reach of fertilisation by insect agency with another variety, not only bears irregularly itself, but the progeny from it are marked by weak constitution. Therefore the block system may not be pushed to extremes, and the arrangement must be such that one variety will not be solely dependent on itself for fertilisation; but by cross-fertilisation by another variety its self-insufficiency will be overcome, and its crops be maintained at a high standard for abundance, regularity, and quality.

This important truth is well known to American orchardists. "It has been known for many years that some varieties of the native Plums are not self-fertile," says "American Gardening," "but it remained for M. B. Waite to apprehend that the same principle applies to many varieties of Apples and Pears as well, and that the reason for failure of fruit crops is evidently to be ascribed in many cases to planting too continuously of single varieties. . . . It was discovered as an incidental feature in experiments to determine if the Pear blight is communicated from flower to flower, and last year definite experiments were made upon a larger scale, which show conclusively that mixed planting is often necessary to the setting of full crops of fruit. This Maxwell Apple orchard was the scene of one of the most important of these experiments, and it has now, therefore, yielded a sufficient crop to pay for all its years of care—but the crop is knowledge, not Apples!" This is where the difference comes in between American and English methods, the first "have been a safe investment and a crop of knowledge," the latter has been marked by the uncertainty of the returns, and the still farther aggregation of prejudice.

There comes a trite saying—known everywhere but in England—from New Zealand, "The British public are so wedded to old notions that generally the rest of the world have adapted any new idea before they awake to its utility." See the *Journal of Horticulture*, May 11th, 1893, page 371. But I have no faith in so tender an Apple as the Northern Spy being a fit stock for Apples in this country. Most

New Zealand plants require a greenhouse or protection in England, and Northern Spy Apple is too tender on the Crab and the English Paradise stock to thrive generally in Britain. There is not anything to dread from American blight in this country, and to advise tender stocks is only another way to secure the supply of the British markets with imported instead of home-grown Apples. Mr. Palmer, of course, does not see this, and it would be well if the grower in this country would bring to bear the latent energy and the indomitable perseverance, so needful at the present time, to transform depression into prosperity. The elements are so abundant in the soil that the magic wand of cultivation, guided by the needful knowledge, would not fail to seal for ever the fate of imported hardy fruits.

basket. The fruits are packed in the baskets in two tiers, and each tier or layer comprises three rows with five Quinces in each of the outside rows and six in the middle row. When the fruits are placed the fuzz [packing material] is rubbed off the top, and the basket is ready for market. The baskets sell on an average for 50 [2s. 2d.] to 75 cents. [3s. 1½d.]. The double extra or keg grade comprises only the large and handsome fruits, and one of these kegs almost invariably sells for a higher price than a full barrel of No. 1."

The above is given as an idea of how careful the American grower is in grading, packing, and so making the most of his produce. It might well be applied in this country, and it would best serve the grower's interests in the long run, for the farmers' and cottagers'

FIG. 78.—CINERARIA MARITIMA VARIEGATA. (See page 444.)

But to return to the account given in "American Gardening" of "an eastern fruit farm" in Western New York. The Quince seems to be a favourite crop, the Maxwells having "two snug little orchards of 30 and 15 acres in extent . . . upon a pleasant slope. Nine thousand trees are now bearing in these two orchards. The 30 acre orchard is set 8 by 15 feet, but this distance is too small. Twelve feet by 12 or even 12 by 15 is now considered to be the ideal distance. But the orchards have given excellent most results. The larger one comprises trees from ten to twelve years old. It has given many good crops, a few of which have reached 1800 barrels [holding 2½ bushels]. The Orange Quince is the only variety grown for general purposes. The Quinces are sorted into three grades, known as XX, X, No. 1, and culls. The No. 1 and culls are shipped in barrels [holding 2½ bushels], the X or extra grade in 15 lb. or peck Grape baskets, and the XX or double extra in bushel kegs. All the profit is made on these two best grades. The extra or basket grade comprises those fruits of medium size and perfect shape, which will require just thirty-two specimens to fill a

fruit only give the costers the trouble of grading and pocketing the difference.

At this stage of the report the writer falls amuck of the growers over excessive pruning, which renders "the top so thick that fruit rot and other fungi are encouraged, and it often prevents the full colouring of the fruit . . . It is said that heading-in is a necessity when trees persist in growing from 2 to 3 feet every season, and this may be true; but it is a question if this much growth should be obtained on bearing trees. The very process of heading-in induces this strong growth, and it may be better to apply more potash and phosphoric acid and less nitrogen and cultivation." Very true. "But when the fuzzy green fruits are as large as a fully grown Hickory Nut they are systematically thinned by hand. This is the first picking, and it is quite as profitable in heavy bearing years as the more enjoyable harvest, which begins in the cool days of late September. And perhaps as much care and skill are necessary in the one operation as the other. The former requires judgment as to how many fruits to pick, and the latter requires

carefulness; for even Quinces must be handled like eggs to avoid the discoloration of bruises."

The extracts show conclusively the pains taken by the American grower to produce the finest and most fruit consistent with the regular bearing of the trees; also the care bestowed in packing and presenting it in such guise as to tempt customers as well as meet the requirements of all classes of buyers, and, of course, to the mutual interests of grower and consumer.

"Plum-growing, however, is perhaps the most absorbing interest of the Maxwells at the present time. The orchards are two, one of 75 acres and another of 5. In the larger orchard every effort has been exerted to make a model commercial plantation, and the results have

limbs. These, tastefully packed in little boxes, find a ready sale, especially in Boston, where the smaller the fruit the better it sells. In general, however, the French is considered to be the best of the Damsons, with a close second in the King. All the Plum orchards, 80 acres in extent, are sprayed three or four times each season for leaf blight, and the curculios are caught on sheets carried on wheelbarrow-like frames. During the past season most remarkable results in combating leaf blight were obtained by spraying with modified eau celeste, to which soap was added to cause it to spread easily and to adhere to the foliage. These Plum orchards are regularly and systematically pruned, and this allows them to be set 15 by 15 feet apart without crowding. The Plum industry has many enemies—curculio, black knot, leaf blight,

FIG. 79.—ALOCASIA SANDERIANA VAR. NOBILIS. (See page 444.)

been most gratifying." Bavay or Reine Claude heads the list. "The tree is a poor grower, and it requires good care and cultivation, and perhaps for this reason it commands a high price. The greater number of people grow the cheap things, and leave the better markets free to their more enterprising neighbours." How true is it of English growers—they grow obsolete varieties, glut the market, and the foreign produce is held back until a favourable opportunity. "There is much call for Prunes, and the Fellemberg answers for all purposes, from the French and Italian to German Prune. It is one of the most reliable fruits of its class, and is distinguished in the orchard by its broad growth." This is the Italian Prune, and might succeed in good situations in this country, especially in the south, as it certainly does in the north of England against a wall, is a good bearer, and the fruit excellent for dessert or culinary purposes.

"To the curious observer who is fortunate enough to drive through this great orchard in August nothing will be so interesting as the long rows of Damsons, with neat little fruits hanging in ropes on the bending

and a host which has not yet been reduced to the limits of the alphabet; yet the crop is a profitable one if the grower know how to produce it."

"Six acres of Peaches—large Hill Chili, Salwey, and Early Rivers—have been an unusually successful venture. A good crop is obtained two years out of three, and the Chili, and sometimes the others, are systematically thinned in early summer. The trees are round-headed standards, and are severely shortened in every spring. Peach culture is an important industry in Western New York, finding its home upon the elevations which skirt the interior lakes, and upon the bolder ridges along Erie and Ontario.

"Seven acres of Cherries—Montmorency and English Morello, an orchard of Seckel [Seckle] Pears, Apricots, 70 acres of Oranges in Florida comprise the remainder of the Maxwell's fruit plantations, all of which are renowned for the most intelligent care and management."

Other matters relating to the nurseries of the Messrs. Maxwell are ably treated by Mr. L. H. Bailey in "American Gardening," but the above lengthy extracts are most likely to interest Journal readers.—G. ABBEY.

#### PROPAGATING NEW OR SCARCE VARIETIES.

AN opportunity will shortly occur whereby the stock of cuttings next November may be augmented with but little trouble. As the plants become well furnished with roots in the 5½-inch pots in which they are now growing they throw up suckers from the base. If these are taken off and inserted single in 2½-inch pots, giving them slight bottom heat, they will quickly make roots, finally shifting them into 6-inch pots and restricting their growth to one stem. The plants will not only produce one fairly large bloom each, but they will throw up many more cuttings next December than will probably the older plants.

#### WALL PLANTS.

Plants growing at the base of a wall where well supplied with water at the roots are now making excellent progress. No time should be lost in thinning out the shoots to prevent overcrowding. A space of not less than 4 inches ought to be provided for every shoot from them at this stage. Where the branches are allowed to grow some length before being secured to the wall they are in danger of hanging down and becoming crooked. In this way they never look so well afterwards as when fastened as growth is made. During dry weather a mulching of manure spread over the surface, a couple of feet away from the wall, will be of great advantage to the plants in maintaining the moisture in the soil, and be a saving of labour also.

#### MADAME DESGRANGE CHRYSANTHEMUMS IN BORDERS.

Where plants of Madame Desgrange and its forms were growing in the borders last autumn and not in any way protected during the winter many are now failing to grow, or they are in a weak state owing to the severity of frost. The blooms which this section produce during the months of September and October in the open border are so useful that no time should be lost in making up any deficiency in their number from the plants that flowered in pots last autumn. A number of plants can be made by pulling in pieces the old stools. These if carefully shaded for a few days after planting, by inverting an empty flower-pot over them, quickly catch hold of the soil when kept moist also, and by September will have grown into useful bushes.—E. MOLYNEUX.

#### MADAME H. FORTAMIER.

FIVE years ago this spring M. Rozain-Boucharlat sent out among the novelties of that season Condor, Geo. Daniels, and Etoile de Lyon, a remarkable and valuable trio of new seedlings. Although he has regularly distributed to the trade a collection of new Chrysanthemums every year since the three above mentioned were raised, there is not a single instance of any that has proved itself worthy of a place in the lists of prominent show flowers. It is to be hoped M. Boucharlat's hand has not lost its cunning. Among his new flowers for 1893, all of which are stated to be of very large build and great width of petal, there is a variety called Madame H. Fortamier, a Japanese with an incurved centre, with ivory white petals, which the raiser claims to be the largest Chrysanthemum known, excelling even Etoile de Lyon in this respect.

#### CHRYSANTHEMUM LITERATURE.

At the recent Exhibition of the R.H.S. at the Temple Gardens Messrs. J. Veitch & Sons displayed a collection of curiosities from Japan. Among them was a book entirely devoted to the Chrysanthemum, entitled "Kikkwa Meiji Sen," which is edited by a native Japanese, and contains a large number of coloured illustrations of flowers of medium size. The title page and names of the flowers are given in English as well as in Japanese, which lends an additional interest to the work. The flowers represented do not in any marked degree vary from those we know already; the colours are of various shades of white, rose, yellow, bronze, and purple, many of the varieties being of the tubular type. Some of our friends who complain of the monotony of Chrysanthemum Shows have here an idea upon which to work. Why not introduce classes for pictures of Chrysanthemums?

#### EARLY CHRYSANTHEMUMS.

A very decided advance was made in the cultivation of the Chrysanthemum when M. Simon Delaux obtained the first large flowered Japanese early blooming varieties, for until then the only earlies in cultivation in this country were of the Pompon type. He has already sent us over several instalments of the new earlies, and hitherto he has had a monopoly of them. This year, however, M. Boucharlat enters the lists with his more fortunate rival, and in announcing the distribution of a dozen new early flowering varieties, claims that they are the result of a rigorous selection, and are absolutely distinct from anything already known. Lovers of outdoor Chrysanthemums or anyone not possessing the convenience of a glass house have plenty to choose from. There are probably now upwards of 300 early flowering varieties.

#### AMERICAN CHRYSANTHEMUM SHOWS.

On the other side of the Atlantic there is an interesting feature adopted. At many of the shows every visitor is presented with what

they call an exhibition souvenir, which is usually a neatly printed little book, containing the work and object of the Society, a list of the officers and executive, a programme of the music performed during the time the Show is open, a list of exhibits and prizewinners, and two or three cultural articles. Some of them are so artistically got up that they well deserve to be carefully kept as interesting contributions to the literature of the popular autumn favourite.

#### NEW FRENCH VARIETIES.

Some people are inclined to think that the French growers have exhausted their resources, and as far as our getting good new show flowers from the other side of the Channel think we might as well give up the idea and look to ourselves or the Americans. The French, however, seem to be of a different opinion, and are sending out this spring 165 new seedlings of the ordinary November type without counting early and hairy sorts. There surely ought to be some grains of corn in so large a quantity of chaff. Any list of first-class Japanese Chrysanthemums for exhibition will show a larger proportion of varieties raised in France than elsewhere.

#### ITALIAN CHRYSANTHEMUMS.

Last spring there were several collections of new seedlings sent out by Italian growers. Unfortunately for them their novelties did not come prominently forward at the shows or in the trade displays. Mr. Jones of Lewisham had a few in fairly good form, Principe di Trabia, a large Japanese of light purple colour, being perhaps the best. I have not heard of any Italian seedlings being offered this year.—OBSERVER.

#### THE TEMPLE SHOW.

As briefly announced in our last issue, this annual Exhibition, held under the auspices of the Royal Horticultural Society in the Temple Gardens, E.C., opened on Thursday, May 25th, and continued the following day. It was, as on former occasions, a grand Show, and fortunately beautiful weather prevailed. There was a large attendance of visitors on both days, so in most respects the Exhibition must again be described a success. As in previous years, the exhibits were arranged in a quartet of marquees, three of which were about 160 feet in length. The centre of one was devoted to Orchids, which formed a special feature, whilst around the sides were arranged in excellent style some grand groups of miscellaneous flowering and foliage plants. Roses in pots were not so extensively shown as we have seen them at this Exhibition, this doubtless being caused by the exceptionally dry weather. Another large tent was filled with Orchids and various greenhouse plants. The Tuberous Begonias and Gloxinias were very fine, as will be seen by the remarks appended. Hardy flowers were well represented, some charming collections coming from all the leading growers. Of fruit, too, there were some interesting exhibits.

#### ORCHIDS.

These were examined by the following members of the Orchid Committee:—Messrs. Harry J. Veitch (Chairman), J. O'Brien, De B. Crawshaw, Thos. Statter, Chas. Pilcher, Hugh Low, H. M. Pollett, W. H. White, A. H. Smee, H. Ballantine, Jas. Douglas, Thos. Bond, and Sir Trevor Lawrence, Bart.

Orchids, as already remarked, made a charming display, the majority of these being arranged in the centre of the largest marquee. Baron Schröder, The Dell, Egham (gardener, Mr. H. Ballantine), sent a large group arranged with admirable taste. There were some very fine species and varieties amongst these, and the whole of them were well grown. Conspicuous amongst others were some magnificent examples of *Cattleya Mendelli*, *C. Lawrenceana*, *C. Mossiae*, a grand plant of *C. Skinneri*, and *Lælia purpurata*. A plant of *Cattleya Skinneri* bore about fifteen spikes, each carrying nearly a dozen flowers. A splendid piece of *Cattleya Warscewiczii Sanderiana* was also much admired. This had four magnificent spathes, the largest carrying six very large flowers with brilliantly coloured lips. *Odontoglossums* were likewise finely represented in this group. Amongst others *O. crispum apiatum* was most noticeable, this plant bearing a grand spike with fifteen flowers of an unusual size, and a large piece of *O. Pescatorei* with six spikes was conspicuous. Some excellent forms of *O. crispum* and *O. vexillarium* also added interest to the display, and the same may be said of the pretty *Vanda teres*. *Cypripediums* were best represented by *C. Stonei*, a plant of which had two spikes, each carrying four flowers; *C. grande*, very fine; *C. caudatum*, *C. Lawrenceanum*, and *C. superciliale* were also good. *Dendrobiums*, *Masdevallias*, and *Epidendrums* were well shown, and these added colour and variety to this splendid contribution, for which a silver cup was awarded. In addition to this group Baron Schröder exhibited a magnificent plant of *Cœlogyne Dayana*, possibly one of the finest specimens ever seen at a show. The plant bore about 800 flowers, these being produced on twenty pendulous racemes, averaging forty blooms on each. Besides awarding a first-class certificate for it the Orchid Committee recommended a silver Flora medal.

Sir Trevor Lawrence, Bart, Burford Lodge (grower, Mr. White) also staged a splendid group of Orchids. These were arranged in excellent style and added much to the beauty of the Show. Noticeable amongst these were *Cattleyas*, *Lælias*, *Odontoglossums*, *Dendrobiums*, *Masdevallias*, and *Cypripediums*. A fine piece of *Lælia purpurata Bryseana* was most conspicuous, as also was a grand plant of the beautiful *Sobralia macrantha*. *Cattleya Mossiae*, Wagner's var., bearing half a

dozen flowers of pure whiteness, with the exception of a lemon coloured throat, was very conspicuous, and the same may be said of the charming *Miltonia vexillaria* Fairy Queen. A fine plant of *Cattleya labiata* bearing nearly a dozen flowers was likewise good, and among *Cypripediums* the pretty *C. superciliosum* and *C. Swianum* were noticeable. A silver cup was awarded for this attractive collection.

A magnificent group was sent by Messrs. F. Sander & Co., St. Albans, and for which a silver cup was awarded. The Orchids in this collection were arranged in masses, which made their characteristics more conspicuous, although there was not so great a variety as in some of the other contributions. Still some splendid forms were noticeable, and the group attracted much attention. A number of *Epidendrum vitellinum* showed up conspicuously against some plants of *Odontoglossum crispum* in variety. At the back of these were good plants of *Phalænopsis*. A mass of *Cattleya Mossiæ* made a display against some grand plants of *Cymbidium Lowianum*, and near to the front of the group were plants of *Anguloa Ruckeri*. Among the other plants in this collection were a small one of *Odontoglossum vexillarium* Leopoldi, G. D. Owen's var., a pretty form, and *O. vexillarium* Princess May, for which an award of merit was adjudged. This is described elsewhere. Awards of merit were also accorded for *Lælia purpurata nobilis*, and *Odontoglossum Wattianum*, Hardy's var., both of which are described elsewhere. *Cattleya Mendelli alba*, *C. Mossiæ* var. Fairy Queen, and *C. Mossiæ* T. R. Watts var., were also noticeable in this group. The last named plant is a charming form with magnificent flowers.

Messrs. B. S. Williams & Sons, Upper Holloway, also sent a large collection of Orchids, attractive in appearance and admirably arranged. Among these were a grand plant of *Cymbidium Lowianum* and a splendid specimen of *Cattleya Lawrenceana*. *Dendrobium densiflorum*, *Cattleya Mendelli*, and *Odontoglossum vexillarium* were also very good. A silver-gilt medal was recommended for this exhibit. De B. Crawshay, Esq., sent a fine form of *Odontoglossum crispum* named Princess May of Teck, which had been named by Her Serene Highness's special permission. Messrs. Hugh Low & Co., Clapton, had a large group of Orchids composed principally of *Cattleyas*, such as *Mossiæ* and *Mendelli* in various forms. A number of *Cypripedium pedatum* and *Odontoglossums* completed the arrangement (silver-gilt Flora medal). Messrs. Low & Co. sent *Cypripedium Volanteum giganteum*, for which an award of merit was adjudged. This is described elsewhere. C. J. Lucas, Esq., Warnham Court, Horsham, had a very fine group, and for which a silver cup was awarded. These were tastefully arranged, and made a most charming display. Amongst others were the beautiful *Cattleya Warscewiczii*, *C. Mossiæ*, *C. Mendelli*, *Lælias*, *Oncidiums*, *Odontoglossums*, and *Masdevallias*. Messrs. J. Cypher & Co., Cheltenham, staged a splendid collection, and a silver cup was awarded. Noticeable amongst these were some grand forms of *Lælia purpurata*. One named *L. p. atro-purpurea* was adjudged an award of merit. This is a striking variety, and is described below. An award of merit was also accorded for *L. purpurata* Niobe. Other good forms were *L. p. Russelliana*, *L. p. The Duchess*, and *L. p. alba*. Some plants of *Odontoglossum vexillarium* added interest to the group. Norman C. Cookson, Esq., Wylam-on-Tyne, had a plant of *Cattleya hybrida* "William Murray," for which a first-class certificate was awarded. This is a splendid hybrid, and is described elsewhere.

Some Orchids were also arranged in another large tent. In this department Major-General E. S. Berkeley, Bitterne, Southampton, had a small collection of *Dendrobium amicum*, and Messrs. Heath & Sons, Cheltenham, sent a group of *Lælia purpurata* and a seedling *Lælia* of merit. H. Bass, Esq., Byrkley, Burton-on-Trent (gardener, Mr. J. Hamilton), had a group of *Cattleya Mossiæ*, the plants being crowded with blooms; a silver Knightian medal was recommended. Messrs. W. L. Lewis & Co., Southgate, had a very fine collection, arranged in a tasteful manner. *Cattleyas*, *Lælias*, and *Odontoglossums* were noteworthy in this exhibit, a small plant of *Cattleya citrina* Lewisiana being most conspicuous. This is a rich yellow flower, with an orange lip. A fine specimen of *Vanda cœrulea* was also conspicuous, and the same applies to *Phalænopsis grandiflora* and *Lælia grandis tenebrosa*; a silver Flora medal was recommended. Messrs. Pitcher & Manda, Hextable, were awarded a silver cup for a large collection of Orchids and other plants. Mr. G. Wythes, gardener to the Duke of Northumberland, Syon House, Brentford, sent a group of Orchids, comprising *Cypripediums* in variety, *Cattleyas*, *Dendrobiums*, and others (silver Flora medal). Messrs. Charlesworth, Shuttleworth & Co., Heaton, Bradford, had a fine group tastefully arranged. Conspicuous amongst these were some good plants of *Oncidium macranthum*, and a splendid specimen of *Lælia purpurata*. An award of merit was accorded for *Lælia Warneri formosa*, which is referred to elsewhere. Some plants of *Lælia tenebrosa* were also conspicuous in this group, for which a silver-gilt Flora medal was recommended. F. W. Wigan, Esq., also sent a collection of Orchids, including some charming species and varieties, and for which a silver-gilt Knightian medal was recommended.

#### GROUPS AND COLLECTIONS OF PLANTS.

The following members of the Floral Committee examined the groups and collections of plants and cut flowers:—Messrs. W. Marshall (Chairman), Chas. Noble, W. Watson, H. B. May, Robt. Owen, Harry Turner, Geo. Stevens, Thos. Godfrey, J. H. Fitt, F. Ross, Chas. Jeffries, J. Jennings, Wm. Bain, H. Herbst, Jas. Walker, John Laing, Walter Furze, C. E. Pearson, C. J. Lucas, and R. B. Lowe.

The groups and collections of various plants were very fine. Messrs. Jas. Veitch & Sons, Royal Exotic Nursery, Chelsea, staged a group of hardy flowering and foliage plants. This contribution was admirably

arranged, and contained, amongst others, grand examples of *Lilium longiflorum* Harrisii, *Hydrangea paniculata grandiflora*, *H. hortensis* Thomas Hogg, *Spiræa astilboidea*, *S. bumalda*, *Clethra alnifolia*, *Azalea Aida*, *A. rosæflora*, *A. Milton*, *Cytisus scoparius* Andreanus, *Andromeda speciosa cassinefolia*, *Acer palmatum sanguineum*, *A. p. palmatifidum*, *A. p. variegatum*, *Weigela rosea* Looymansii aurea, *Syringa japonica*, *Eulalia japonica variegata*, and *Cornus sanguinea variegata*. Messrs. J. Veitch & Sons also had a collection of *Streptocarpus* and a number of *Gloxinias*, fresh and varied in colour. The best of the *Gloxinias* were *Monarch*, *Celia*, *Claudia*, *Claribel*, *Sylvia* and *Hector*, the last named being a very bright variety. Plants of *Caladium Souvenir de Para* were also shown by Messrs. Veitch. This variety was figured in the *Journal of Horticulture* for March 30th, 1893. The same firm sent *Anthurium Rothschildianum*, a pretty hybrid, and some new plants, including *Begonia decora* (figured in *Journal of Horticulture* for March 9th, 1893), *Strobilanthes Dyerianus* (illustrated in the *Journal* for May 4th, 1893), *Begonia Maria Louise* (figured in the *Journal* for September, 1st, 1892) and *Rhododendron Ariel*. An award of merit was adjudged for the last named plant. This *Rhododendron* is described under the "Certificates and Awards." A silver cup was awarded Messrs. J. Veitch & Sons for their interesting exhibits.

A group of foliage and flowering plants was contributed by Messrs. B. S. Williams & Son, Upper Holloway, N. The exhibit consisted of *Azaleas*, *Spiræas*, *Palms*, *Imantophyllums* (*Clivias*), *Anthuriums*, *Oranges* carrying fruit, *Ericas*, *Ferns*, *Crotons*, *Amaryllises*, and *Dracenas*. Messrs. E. D. Shuttleworth, Peckham Rye, S.E., arranged a charming group of miscellaneous plants, including *Palms*, *Ferns*, *Liliums*, *Zonal Pelargoniums*, *Dracenas*, and *Crotons*. The same firm also exhibited a noteworthy group of *Cycads* in variety. A silver-gilt medal was recommended to be awarded this rising firm for their exhibits. Mr. H. J. Jones was represented by a collection of *Show and Fancy Pelargoniums*, amongst the most striking of which were *Princess May*, *Mrs. Stone*, *Venus*, *Prince of Orange*, *Agnes Cook*, *Empress of India*, *Mabel*, *Marguerite*, *Eclipse*, *Blanche*, *Sir Trevor Lawrence*, *Flora*, *Hercules*, *Rose Queen*, and *Little Richard*. A silver Flora medal was recommended for this exhibit. A yellow *Chrysanthemum*, named *Chas. Davis*, a sport from *Vivian Morel*, was also shown by Mr. Jones, who likewise had plants of his *Ryecroft Surprise* Ivy-leaved *Pelargoniums*, an exceedingly pretty variety.

Messrs. J. Laing & Son, Forest Hill, S.E., had a collection of flowering and foliage plants, amongst which specimens of *Anthurium Scherzerianum magnificum*, *Ferns*, *Palms*, *Croton Challenger*, *C. Reidi*, *C. Morti*, *C. Prince of Wales*, and *C. Thomsoni* (award of merit), *Dracæna Lindenii*, *Coleus Stanstead Beauty*, *Dracæna norwoodiensis*, *D. australis variegata*, and *Caladiums* were particularly noticeable. Orchids were excellently represented with *Cattleyas* and *Odontoglossums*. A group of magnificent *Caladiums* was staged by Messrs. J. Laing & Son. The most noticeable varieties in this exhibit were *Candidum*, *Triomphe de l'Exposition*, *Souvenir de Madame Bernard*, *Aïda*, *John Laing*, *Luddemannii*, *L'Automne*, *Clio*, *Monsieur de Halloy*, *Gerard Dow*, *Reine de Danmark*, *Mrs. Harry Veitch*, and *Ibis Rouge*. Awards of merit were adjudged for the two last-named varieties. This exhibit was unquestionably one of the features of the Show. A charming and effective group of *Tuberous Begonias* was also arranged by Messrs. J. Laing & Son. The *Begonias* were intermingled with *Ferns*, and the effect produced was an excellent one. The best amongst the doubles were *Duchess of Teck*, *Duke of York*, *Lady Brooke* (award of merit, see below), *Miss French*, *Purity*, *Lord Esher*, *Lady Dorrington*, *Earl of Craven*, *Henshaw Russell*, *Lord Brooke* (award of merit, see below), *Stanstead Gem*, *W. Clifford*, *Mrs. Regnarte* (award of merit), *Mrs. Hudson*, *Baron Schröder* (award of merit), and *Beauty of Belgrove*. The singles included *H. M. Stanley*, *Duchess of Leinster*, *Mr. Wm. Miller*, *Countess of Westmoreland*, and *Lady Scott*. A silver cup was awarded Messrs. J. Laing & Son for the *Caladiums* and *Begonias*, and for groups of miscellaneous plants the Floral Committee recommended a silver-gilt medal.

Messrs. Hugh Low & Co., Clapton and Bush Hill Park Nurseries, exhibited a collection of well grown *Ericas*, prominent amongst which were *E. ventricosa grandiflora*, *E. v. globulosa*, *E. perspicua erecta*, *E. Spenceri*, *E. v. coccinea minor*, *E. depressa multiflora*, *E. candidissima*, *E. Cavendishi*, *E. intermedia*, and *E. v. rosea* (silver-gilt Flora medal). Mr. Chas. Turner, Royal Nurseries, Slough, sent plants of *Souvenir de la Malmaison* *Carnations* which were very fine indeed. A basket of *Germania Carnations* was also shown by Mr. Turner, and plants of *Turner's Crimson Rambler Rose* (silver-gilt Flora medal). Messrs. John Peed & Son, Roupell Park Nurseries, Norwood Road, S.E., sent a beautiful group of flowering and foliage plants which included *Begonias*, *Cypripediums*, *Odontoglossums*, *Hydrangeas*, *Caladiums*, *Liliums*, *Azaleas*, *Crotons*, *Dracenas*, *Palms*, *Ferns*, and *Anthuriums*. A silver-gilt Flora medal was recommended.

In inviting groups of greenhouse and stove foliage plants the Society have made a fresh and what should be a very popular departure. Mr. A. Offer, gardener to J. Warren, Esq., Hand Cross Park, Crawley, staged a very fine group in this section, and was awarded a silver cup. His exhibit included fine specimens of *Crotons*, *Cycads*, *Palms*, *Marantas*, *Dracenas*, and *Ferns*. Mr. Offer also showed a group of six hardwooded greenhouse plants in flower. Excellently trained and flowered specimens of *Azalea Brilliant*, *Erica Cavendishi*, *Hedera fuchsoides*, *Aphellexis macrantha rosea*, *A. m. purpurea*, and *Dracophyllum gracile* were staged. P. Crowley, Esq., Waddon House, Croydon, was also awarded a silver cup for a group of foliage plants, well

grown by his gardener, Mr. King. Palms, Dracænas, Alocasias, Caladiums, Adiantums were included in this contribution.

Messrs. Wm. Cutbush & Son, Highgate Nurseries, exhibited a charming group of miscellaneous plants. Ericas, Palms, Dracænas, Hydrangeas, Crotons, and Liliams were particularly prominent in this exhibit, for which a silver-gilt medal was recommended. Messrs. Jas. Carter & Co., High Holborn, had collections of Streptocarpus, Mimuluses, Gloxinias, and Petunias. The colours in the Gloxinias were very diversified, ranging from a rich dark purple to a pure white. The Petunias exhibited by this firm were very fine. The same firm also staged a collection of Calceolarias of good habit and varied colours. A silver-gilt Flora medal was recommended for the various exhibits staged by Messrs. Carter & Co.

#### ROSES, FERNS, AND BEGONIAS.

Messrs. G. Paul & Son, The Old Nurseries, Cheshunt, staged a magnificent group of Roses and Cannas. Prominent amongst the former were Innocente Pirola, Edouard Morren, Juno, Madame de Watteville, Madame Hoste, Lady Alice, Crimson Queen, Mons. Furtado, Ulrich Brunner, Celine Forestier, Copper Austrian (Briar), Harrisoni (Briar), and a single Rose Carmine Pillar. The Cannas were finely represented by Professor David, Madame Crozy, Sophie Buckner, Paul Bruant, Chas. Moore, Primrose, Admiral Gearvis, Victor Hugo, and Miss Sarah Hill. The same firm also exhibited a few baskets of Rhododendrons, including Marchioness of Lansdowne, Lady Eleanor Cathcart, Purity, Michael Waterer, Miss Holford, Mrs. Russell Sturges, Vauban,

FIG. 80.—PRIMULA REIDI. (See page 444.)

Ingrami, and Kate Waterer. A silver cup was awarded Messrs. Paul and Son. Mr. Wm. Rumsey, Joyning's Nurseries, Waltham Cross, exhibited a group of Roses in pots, and also boxes of cut Roses. Notable amongst the kinds in pots were Madame Hoste, Queen of Queens, Lady Helen Stewart, Edouard Morren, Prince Camille de Rohan, Merveille de Lyon. A box of Maréchal Niel was very striking. In the other boxes were to be seen Niphotos, Reine Marie Antoinette, Grace Darling, Eugénie Verdier, and Austrian Briar Harrisoni. A silver-gilt medal was recommended.

Mr. Frank Cant, Rose-grower, Braiswick, Colchester, exhibited five boxes of cut Roses. The varieties represented in this collection comprised flowers of Maréchal Niel, Dupuy Jamain, The Bride, Madame Victor Verdier, La France, Madame Lambard, Souvenir d'un Ami, Madame Bravy, Catherine Mermet, and Madame Hoste (silver Flora medal). Messrs. G. Cooling & Sons, Bath, sent boxes of cut Roses, including the single varieties. The Austrian Briars and Persian Yellow Roses were especially good, as likewise were the Moss Roses. Mr. George Mount, Canterbury, also sent a number of cut Roses. The best of these were Catherine Mermet, The Bride, Mrs. J. Laing, Dupuy Jamain, Marie Baumann, and Maréchal Niel. Messrs. Keynes, Williams & Co. sent two boxes of hybrid Sweet Briars and Austrian Briars for which a silver medal was recommended. Lord Penzance, Eshing Park, Godalming (gardener, Mr. G. Baskett), also sent some beautiful hybrid Sweet Briars, and a silver gilt Flora medal was recommended.

Messrs. Sutton & Sons sent a charming group of Gloxinias. These included the new varieties Duke of York, Her Majesty (pure white), Empress of India, and Netted Queen, for which an award of merit was adjudged. Plants of the recently introduced Nemesia Strumosa Suttoni in pots were also shown by the same firm. A silver-gilt medal was recommended. C. J. Tasker, Esq., Brentwood, Essex (gardener, Mr. J. Perry), had boxes of Canna blooms and cut Roses (silver Banksian medal). Messrs. J. Peed & Sons, Roupell Park Nurseries, Norwood, sent a collection of Gloxinias arranged with Maidenhair Ferns (silver-gilt

medal). Messrs. F. Sander & Co., St. Albans, staged a collection of new and rare plants, comprising Cineraria maritima variegata (award of merit—see engraving, page 438). Alocasia Sanderiana var. nobilis (first-class certificate—see page 439). Blandfordia nobilis, Dipladenia atro-purpurea, Anthurium albanense, Aristolochia gigas var. Sturtevantii, Arisæma fimbriata, and Alocasia Sanderiana magnifica.

Ferns were well represented. Mr. H. B. May, Dyson's Lane Nurseries, Upper Edmonton, had a large collection. These comprised Gymnogramma Wettenthalianum, Davallia elegans, Nephrolepis recurva, Dicksonia squarrosa, Lomaria gibba, Pteris tremula Smithiana, Pteris Victoria, P. nivalis, Cibotium regale, and Asplenium marginatum. A first-class certificate was awarded for the last named Fern. A silver cup was recommended for the whole collection. Mr. May also had plants of Cineraria maritima aurea variegata (an award of merit), and Duke of York Carnation, a dark Clove-scented variety. Messrs. W. & J. Birkenhead also had a splendid collection of Ferns, comprising stove, greenhouse, and hardy varieties, for which a silver cup was awarded. Amongst these were Adiantum macrophyllum bipinnatum, Davallia tenuifolia Veitchiana, Pteris Victoria, Davallia fijiensis elegans (award of merit), Athyrium setigerum grandiceps (award of merit), and Nothochlæna mollis (award of merit). The hardy Ferns were good, and amongst them were some grand forms. The best were Athyrium f.f. setigerum capitatum, A. f.f. Frizellæ corona, and A. f.f. setigerum Victorice.

Begonias were exceptionally good, some splendid groups being staged by the leading growers. Messrs. H. Cannell & Sons, Swanley, sent a most magnificent group of double and single varieties, for which a silver cup was awarded. Amongst the singles were Earl Grosvenor, Seven Inch, the name of which is peculiarly appropriate, as it denotes the size of the individual blooms; Miss Agnes Stewart, Mrs. Guthrie, Duchess of Westminster, Countess of Dunmore, Mrs. John Thorpe, Danebrog, and Gigantea. The double varieties included Miss Edith Wynne, General Owen Williams, J. Lyon, Lady Roberts, Leopold Rothschild, Lord Llangattock (award of merit, see below); Golden Queen, Mrs. Lynch, Mrs. French, Lady Henry Bruce, Miss Elsey Wire, Mrs. Walter Palmer, Miss Leith, Mrs. W. B. Miller, and Miss E. Terry. The same firm also staged a collection of Gloxinias, containing some very beautiful forms. Messrs. Cannell also showed a group of Improved Raspail Pelargoniums. Mr. T. S. Ware, Hale Farm, Nurseries, Tottenham, N., exhibited a grand collection of double and single Begonias. Amongst the varieties shown were Princess May, Bexley Gem (award of merit); Miss Jennie Fell, Beauty of Belgrove, Elegans (award of merit); Claribel, Lord Byron, Viscountess Cranbrook, Picotee, Iona, Couronne, Henshaw Russell, and Alba Magna. Messrs. J. Laing & Sons also had Begonias, but these have already been mentioned.

#### HARDY PLANTS AND CUT FLOWERS.

Hardy cut flowers and alpine plants were extensively shown. Messrs. J. Backhouse & Sons, The Nurseries, York, staged a splendid collection of alpine and herbaceous plants, for which a silver cup was awarded. These included choice Saxifragas, Ramondia pyrenaica, Dianthus, Aster alpina albus, and Ferns. The Guildford Hardy Plant Nursery Co. had a grand collection of alpines, arranged in a charming manner (silver-gilt medal). Among these were some plants of Rhododendron ferrugineum majus full of flower, Saxifragas, and miniature Campanulas. Pernettyas were also represented in this group. Messrs. E. D. Shuttleworth & Co., Peckham Rye, also had hardy flowers, including Iris and Delphiniums in variety. Messrs. J. Laing & Son also had hardy flowers. A silver medal was recommended in each case. Messrs. Harkness and Sons, Bedale, sent a collection of hardy cut flowers, comprising Pyrethrums in variety, Poppies, Centaureas, Campanulas, and Heuchera sanguinea (silver-gilt Flora medal). Messrs. Cutbush & Sons, Highgate, had a large collection of hardy flowers, including Pyrethrums, Iris, and Ixias. The latter were very fine, and attracted attention, especially I. viridiflora. Some sprays of Campanula persiciflora alba grandiflora were noticeable in this group, as also were the Oriental Poppies (silver medal). Mr. M. Prichard, Christchurch, had hardy flowers, amongst these being a grand spike of Eremurus robustus, Aquilegias in variety, and Poppies (silver-gilt Flora medal). Messrs. J. Cheal & Sons had plants of Tom Thumb Dahlias in pots and a very fine collection of Violas and hardy flowers (silver medal). Messrs. Collins Bros., Hampton, sent a large collection of Iris of various kinds (silver medal). Mr. C. G. Van Tubergen, Haarlem, staged a number of cut flowers, including grand blooms of Iris Lorteti and Calochorti (silver medal).

Tulips were finely shown by J. W. Bentley, Esq., Stakehill, Castleton, Manchester. The best blooms in this collection were Sulphur, bizarre breeder; Friar Tuck, flamed; George Hardwick, feathered; May Queen, feathered; Sir J. Paxton, flamed; and Dr. Hardy, flamed (silver medal). Messrs. P. Barr & Sons also had a collection of English Tulips. The blooms were fresh and varied in colour, the various types being well represented. Messrs. Barr & Sons also had a large collection of hardy flowers—Ixias, Gladioli, Iris, Poppies, and Violas, all in excellent condition. We have seldom seen a finer collection of hardy flowers. A silver cup was awarded for this meritorious contribution. Mr. T. S. Ware, Tottenham, arranged a group of hardy plants containing amongst others Pyrethrums, Anthericum grandiflorum, Iberis, Irises, Spiræas, Liliams, Saxifragas, Pæonies, Poppies, Antirrhinums, Delphiniums, and Veronicas (silver-gilt Flora medal). Messrs. Kelway & Son, nurserymen, Langport, contributed a collection of hardy flowers, including some magnificent Pæonies, Irises, Pyrethrums, Gaillardias, and a very fine collection of Delphiniums. The same firm also had a collection of Amaryllises. A silver-gilt Flora medal was recommended.

Messrs. Dobbie & Co., Rothesay, N.B., staged a magnificent collection of Violas and Pansies. Amongst the more prominent of the Violas were Tory, H. W. Stewart, Dawn of Day, Countess of Kintore, Joy, Countess of Hopetoun, Mrs. H. Bellamy, Wonder, Mrs. Kinnaid, Lemon Queen, Gipsy Queen, Laverock, Topsy, Goldfinch, and Rob Roy (silver-gilt medal). Messrs. Jas. Cocker & Son, nurserymen, Aberdeen, staged a charming collection of hardy plants, including Violas, Poppies, Polyanthus, Centaureas, and Geums, for which they were recommended a silver Banksian medal. The same firm also staged Polyanthus Queen Victoria, for which an award of merit was accorded (see below). Mr. T. Gifford, Montague Nurseries, Tottenham, N., staged a collection of blooms of *Paeonia albiflora* and *P. a. rosea*. Mr. A. Smith, Prospect House, Downley, High Wycombe, sent some Violas, Pansies, and cut Roses.

#### MISCELLANEOUS.

Mr. Bain, gardener to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, sent a group, including *Richardia Elliotiana*, *Cyrtanthus Hut-toni*, *Anthurium Burfordiense*, *A. Andreanum*, *A. Edwardsi roseum*, *A. Laingi*, *A. Andreanum sanguineum*, and some seedlings. G. A. Farini, Esq., Dartmouth Lodge, Perry Vale, Forest Hill, staged a very creditable collection of double Begonias, comprising some excellent plants, especially when it is considered that Mr. Farini has only grown for Begonias two years (silver medal). Messrs. Reid & Borneman, Sydenham, S.E., contributed a small group of a new *Lobelia Gold Sapphirs*. The same firm also arranged a group of flowering plants, including Pelargoniums, Hydrangeas, Lilliums, Cannas, Amaryllises, Ferns, and *Asparagus plumosus* (silver medal). Mr. J. Walker, nurseryman, Thame, Oxon, staged a collection of Zonal Pelargoniums, comprising double and single varieties (silver medal). Messrs. W. Balchin & Sons, Hassocks, had a group of *Leschenaultia biloba major*, and some blooms of *Pyrethrum Jubilee*, a rich crimson variety. Messrs. R. Veitch & Sons, Exeter, sent plants of *Vallota purpurea* var. *Perfection*, *Crimson Gem*, and *Delicata*. An award of merit was adjudged for the last named. G. F. Wilson, Esq., Heather Bank, Weybridge Heath, secured a first-class certificate for a plant of *Primula Reidi*, which is described elsewhere. Messrs. B. S. Williams & Son had some new *Dracaenas* and *Amaryllises*. Awards of merit were adjudged for *Dracaena Lord Wolseley* and *Amaryllis Lord Roberts*. Mr. C. Turner, Slough, had blooms of Iver White Carnation; and Mr. C. Blick, Hayes Common, sent Carnations. Awards of merit were adjudged for the Carnations Churchwarden and Mrs. Seymour Bouverie, both good varieties. They are described under "Certificates and Awards."

Bouquets were fairly well shown. Mrs. Thewles, Birmingham, sent a bride's bouquet composed of *Odontoglossums*, white Carnations, *Pan-cratiums*, and Grasses (silver-gilt medal). Mr. J. Chard, Stoke Newington, had examples of Arcadian decorations tasteful in arrangement (silver medal). Messrs. Perkins & Sons, Coventry, sent a number of bouquets and wreaths composed of Orchids and Carnations (silver-gilt medal). Mrs. Hodgkins, 5, Beaumont Avenue, Didsbury, staged a most interesting collection of skeletonised flowers and leaves.

#### FRUIT.

The following members of the Fruit Committee examined the collections:—Philip Crowley, Esq., Chairman; with Dr. Hogg and Messrs. H. J. Pearson, Harrison Weir, W. Warren, G. Norman, T. J. Salt-marsh, J. Willard, A. Young, J. Cheal, A. H. Pearson, A. Dean, G. Reynolds, G. W. Cummins, G. Wythes, J. Hudson, T. F. Rivers, E. Burrell, F. Q. Lane, Arthur G. Sutton, W. H. Divers, G. Woodward, J. A. Laing, and J. Wright.

Though the display of produce was by no means extensive there were, nevertheless, some noteworthy exhibits. Mr. Rivers' group of Early Rivers Nectarine trees in pots was decidedly unique, inasmuch as it will be strictly accurate to say that all the world, apart from Sawbridgworth, could not produce its equal as representing the earliness, size, and colour of this splendid Nectarine. There were two dozen trees in 10 and 12-inch pots—pyramids, low bushes, and standards, each bearing about a dozen large and handsome bronzy-red fruits; such fruits as have sold for 48s. a dozen in Covent Garden. The Committee unanimously recommended a silver-gilt medal for this group, but the Council went a step in advance and granted a silver cup. This was certainly well merited when it is considered that Mr. Rivers was not only the grower of the trees, but the raiser of the variety. It may be expected that Early Rivers Nectarine will eventually find its way into gardens all over the kingdom and beyond our shores. A low standard tree was figured on page 159, *Journal of Horticulture*, August 20th, 1891, and a dwarf one is represented in the engraving fig. 81.

The next most noteworthy exhibit in the tent was from Mr. S. Mortimer, Rowledge, near Farnham, and consisted of Cucumbers, Melons, and Tomatoes in considerable numbers and of splendid quality. The tender-looking Cucumber Success or Sutton's Peerless (certificated last year) was temptingly displayed, and there were boxes of two new varieties with familiar names—Duke of York and Princess May. Though the fruits were as near perfection in shape as could well be imagined, the varieties did not stand out with sufficient distinctness to receive a special award. The Tomatoes comprised boxes of Sutton's Earliest of All and Perfection, excellent fruits; Jones' Perfection, smooth and handsome; Sharpe's Plentiful, flattish smooth, with Conqueror and Magnum Bonum corrugated. Mr. Mortimer staged a dozen fine fruits of the Conqueror Melon, a free bearing and good old variety for market, also satisfactory examples of Sutton's Al, Empress, Hero of Lockinge and Golden Perfection. A new variety, Duke of York, was too small, and not in the best of condition. A silver-gilt Knightian medal

was unanimously recommended for the collection by the Committee and confirmed by the Council.

Mr. G. Featherley, The Vinceries, Gillingham, Kent, had a highly meritorious exhibit, including baskets of Black Hamburg and Muscat of Alexandria Grapes, both excellent; Carter's Model Cucumbers, smooth and fine; Austin's Eclipse Tomatoes an excellent sample; good Peaches, and a basket of Ne Plus Ultra Dwarf Kidney Beans. A small silver medal was unanimously recommended by the Committee, but the Council in the exercise of their judgment and power granted a silver-gilt Knightian. From Lord Foley's gardens, Ruxley Lodge, Esher, Mr. Miller brought a creditable collection of fruit, including good dishes of Sir Joseph Paxton, Noble, and the White Bicton Pine Strawberries, also Black Heart and Bigarreau Cherries, with Ruxley Lodge Melons and Norfolk Beefing Apples. The Committee recommended a bronze medal for the exhibit, but the Council granted a silver Banksian medal. Similar improvements on the Committee's recommendations were made in respect to excellent Brown Turkey Figs and Lord Napier Nectarines from Mr. Wythes; also in the case of six very good dishes of Figs from E. Dresden, Esq., Livermore Park, Bury St. Edmunds (gardener, Mr. J. C. Tallack), but Mr. J. McIndoe's award of a vote of thanks for attractive fruits of Best of All Melons, an excellent dish of Nectarines, and two dishes of Peaches appeared to be held by the Council as

FIG. 81.—DWARF NECTARINE TREE.

a sufficient recognition. Had the Committee been aware of the disposition of the Council to be more generous on the occasion of a Temple Show than at the fortnightly meetings it is practically certain that a medal of some kind would have been recommended for Mr. McIndoe's collection, and certainly no generosity was shown to him by the supervisors. It appears the Council decided to award no bronze medals at this Show, but the Committee were not aware of this, though the Chairman is a member of the governing body, and proceeded with their duties in the ordinary way.

Several Melons were staged. Mr. C. Ritchings sent capital fruits of Ritchings' Perfection, a good Melon, previously certificated. He also exhibited a seedling from it, but could not retard the ripening process to "time" it for the occasion. Mr. N. Molyneux, Rookesbury Park, seems to have been in much the same position with his seedling from Hero of Lockinge and Scarlet Gem, which ripens a fortnight earlier than the last-named, for the fruit was in a state of ferment, and so were other fine Melons from Whitfield Gardens, Hereford. Mr. J. McKinley, The Gardens, Belmont, Hereford, exhibited twelve large straw-coloured Melons not to be cut, and was accorded a vote of thanks. A similar mark of recognition was entered for a collection of Apples from Messrs. James Veitch & Sons, Chelsea.

A highly interesting collection of woods and seeds, also bottled and preserved fruits indigenous to Japan was sent from that country by Mr. James H. Veitch of the Royal Nurseries, Chelsea. Among these were some Bamboo shoots said to correspond with Asparagus, and some

preserved Peaches. About 128 kinds of cereal and other seeds were sent by Mr. Veitch, as also were some coloured illustrations of Chrysanthemums as grown in Japan. This collection must be regarded as a valuable addition to the Veitch museum at Chelsea.

#### CERTIFICATES AND AWARDS.

*Celogyne Dayana* (Baron Schröder).—A magnificent plant of this well-known Orchid was shown. It bore twenty pendulous racemes, each bearing on an average forty flowers, in all about 800 blooms (first class certificate and silver Flora medal).

*Lælia purpurea Niobe* (J. Cypher & Son).—A charming form, with bright rosy mauve sepals and petals, the lip deep purplish red, paler margin (award of merit).

*Odontoglossum vexillarium Princess May* (F. Sander & Co.).—An exceedingly pretty form, having large white flowers with a tinge of pink and yellow in the centre (award of merit).

*Odontoglossum Wattianum Hardy's var.* (F. Sander & Co.).—A showy form, with flowers borne on spikes about 2 feet in length. The sepals and petals are pale yellow, heavily blotched with chocolate. Lip whitish, also spotted brown (award of merit).

*Lælia purpurata nobilis* (F. Sander & Co.).—This is a grand variety. The flowers are large in size and richly coloured. The sepals and petals are rosy mauve on a white ground, the frontal portion of the lip being a deep crimson with a fainter edge. The throat is yellowish striped with brown (award of merit).

*Cattleya hybrida William Murray* (N. C. Cookson, Esq.).—This is a charming plant, and is the result of a cross between *C. Mendelli* and *C. Lawrenceanum*. The sepals and petals are of a rosy mauve shade, the lip being a rich magenta crimson with a white and lemon throat (first-class certificate).

*Cypripedium Volonteanum giganteum* (Hugh Low & Co.).—This is a massive form of *C. Volonteanum*. The dorsal sepal is green, as also is the centre of the petals, which are spotted brown and margined with pink (award of merit).

*Lælia purpurata atro-purpurea* (J. Cypher & Son).—This is a splendid form. The sepals and petals are pure white, the lip being of rich purplish crimson (award of merit).

*Cattleya Warneri formosa* (Charlesworth, Shuttleworth, & Co.).—A very fine variety. The sepals and petals are pinkish mauve, the lip being rich crimson with a white fimbriated edge (award of merit).

*Anthurium crystallinum fol. var.* (Pitcher & Manda).—This is a variegated foliage form of *A. crystallinum*. In a young condition half of each leaf is creamy white, the other portion being bright green blotched with cream. When well developed the leaf is more than a foot in length, and the variegation less conspicuous (first-class certificate).

*Anthurium Parisiente* (Sir Trevor Lawrence).—The spathes of this species are medium sized and of a pale salmon-pink shade (award of merit).

*Aloeasia Sanderiana nobilis* (F. Sander & Co.).—This is a grand plant with noble foliage. The leaves on the plant staged were about 15 inches in length, and of a glaucous dark green shade, the whitish ribs and veins being most conspicuous. It will doubtless prove a useful addition to decorative stove plants, inasmuch as the foliage is of an attractive appearance. The illustration on page 439 depicts the character of the leaves (first-class certificate).

*Begonia Lady Brooke* (J. Laing & Son).—A double variety with well formed flowers of a salmon pink shade (award of merit).

*Begonia Lord Brooke* (J. Laing & Son).—A bright crimson double variety, the flowers being large and well formed (award of merit).

*Begonia Mrs. Regnarte* (J. Laing & Son).—A double variety, with excellent flowers of rich yellow shade (award of merit).

*Begonia Lady Llanngatcock* (H. Cannell & Son).—This is a splendid double variety, with large flattish rich crimson flowers (award of merit).

*Begonia Bexley Gem* (T. S. Ware).—A double variety, with pink flowers of a pretty tint (award of merit).

*Begonia elegans* (T. S. Ware).—A charming variety, with double flowers, pinkish tinge, the petals having fimbriated edges (award of merit).

*Gloxinia Netted Queen* (Sutton & Sons).—An exceedingly pretty variety. The flowers are large, upright, of a rich pink colour netted white (award of merit).

*Asplenium marginatum* (H. B. May).—This is an attractive Fern with long fronds of a bright green colour and bold pinnæ (first-class certificate).

*Cineraria maritima aurea variegata* (H. B. May).—This is a showy plant with rich-coloured foliage and stems. The leaves are green covered with a silvery gloss, and yellow edges (award of merit).

*Cineraria maritima variegata* (F. Sander & Co.).—This is apparently the same plant as was shown by Mr. May, and described above. Those exhibited by Messrs. F. Sander & Co. were, however, dwarfer in habit, and in this condition would be well adapted for bedding. The illustration on page 438 portrays the variegation on the foliage (award of merit).

*Nothoehlana mollis* (W. & J. Birkenhead).—A new dwarf-growing Fern, with small fronds and minute pinnæ (award of merit).

*Davallia fijiensis elegans* (W. & J. Birkenhead).—A graceful variety, with fronds about 18 inches in length, and small pinnæ (award of merit).

*Athyrium setigerum grandiceps* (W. & J. Birkenhead).—A pretty form with bright green cristated fronds (award of merit).

*Rhododendron Ariel* (J. Veitch & Sons).—This is a charming greenhouse species with sulphur yellow flowers (award of merit).

*Hybrid Sweet Briar Amy Roberts* (Keynes, Williams & Co.).—A charming hybrid with pink flowers of a medium size (award of merit).

*Amaryllis Lord Roberts* (B. S. Williams & Son).—A pretty variety with medium-sized flowers striped white and pink (award of merit).

*Dracæna Lord Wolseley* (B. S. Williams & Son).—A useful decorative variety with bronzy leaves margined red (award of merit).

*Carnation Mrs. Seymour Bouverie* (C. Blick).—A pretty variety, terra cotta shade, flushed carmine (award of merit).

*Carnation The Churchwarden* (C. Blick).—This is a seedling from *Souvenir de la Malmaison*; the flowers are large, red, and clove scented (award of merit).

*Polyanthus Queen Victoria* (J. Cocker & Sons).—This is a semi-double gold laced Polyanthus, with a rich orange centre (award of merit).

*Vallota purpurea var. delicata* (R. Veitch & Son).—A charming blush coloured variety of the well-known type *V. purpurea*. The flowers are medium in size (award of merit).

*Heimerocallis Apricot* (G. Yeld, Esq.).—This is a pretty variety with apricot yellow flowers. It appears to be a profuse bloomer, and should prove a welcome addition to these hardy plants (award of merit).

*Caladium Mrs. Harry Veitch* (J. Laing & Son).—An attractive variety with large red leaves blotched with green and veined with dark red (award of merit).

*Caladium Ibis Rouge* (J. Laing & Sons).—A dull white ground with bright red veins (award of merit).

*Rose Carmine Rose* (G. Paul & Son).—A new single variety with bright carmine flowers about 3½ inches in diameter, exceedingly pretty in the bud (award of merit).

*Croton Thomsoni* (J. Laing & Son).—A useful decorative plant with yellow leaves blotched green, the young foliage having a very pale green shade (award of merit).

*Begonia Baron Schröder* (J. Laing & Son).—A double variety with bright orange scarlet flowers of fine form (award of merit).

*Delphinium John Thorpe* (Kelway & Son).—A double variety of exceptional merit; flowers rich purple shaded blue, inner petals white (award of merit).

*Primula Reidi* (G. F. Wilson, Esq.).—This is one of the most charming Primulas in cultivation, and by some growers is considered quite hardy. The plant exhibited, according to a statement shown with it, had been grown in the open border since 1886, and was taken up and put in a pan on the 23rd ult. The flowers are pure white, and delightfully fragrant. This Primula is deserving of extended culture. The small engraving on page 442 illustrates the bloom and leaf (first-class certificate).

#### THE SCOUNDREL SPARROW.

I AM obliged to "W. R. Raillem" for his note on page 393. I was inclined to adopt a theory frequently advanced, that it was thirst which caused the sparrow to seek for moisture among the buds and blooms of flowers and trees, and that in search of this it unavoidably caused some damage. In view, however, of your correspondent's statement that a stream of open water runs through his grounds I feel that we must abandon this theory, and fall back on the only possible one which occurs to me—viz., that the habits of the birds vary in different localities possibly from peculiarities of climate or food which we cannot properly understand.

I hope the time may not come when I shall be compelled to destroy the sparrows. When I purchased my present house and garden these birds were "in possession." This is now rather over nine years ago, and I cannot say that I see any increase in their numbers. They must emigrate, and it is to be hoped they carry their orderly manners to the land of their adoption, and be as considerate to their hosts as they have been to me. I do not "hold a brief" for the sparrow, and must admit that in many cases he eats a great quantity of Oats, especially in fields surrounded by high or badly kept hedges. Whether he properly pays for his damage to the Oats by the destruction of pests and seeds or buds of weeds may, however, be a moot question.

I do not in the slightest hint that "W. R. Raillem" is wrong in his crusade against the sparrows, as if I were as satisfied as he is that they do damage I should likewise reduce their numbers. I have found domestic pigeons do a great deal of damage to flowers and also to young Peas, and some starlings which have been attempting to evict the sparrows from their nesting places in a neighbouring garden have been detected using Primroses and green haulm of Potatoes in their nesting materials.—S. ARNOTT.

WILL Mr. Witherspoon (page 393) kindly take notice that when he speaks of what he has seen himself, he says, "These are stern unattackable facts;" but in alluding to my statement that I had seen sparrows plucking off Apple blossom, and should therefore declare war upon them, he says, "Whilst poking into the bloom truss to secure the snugly ensconced caterpillar, the sparrow has been seen to drop a stray petal, and he is not only to be censured, but he is to be utterly exterminated." (?) And will he also say whether he considers this a courteous way of conducting correspondence? My eyes have served me well in my observations of birds for nearly half a century, and I feel bound to defend them against such unwarrantable imputations.

Mr. Witherspoon uses the term "birds" several times in his letter; but of course there are birds and birds. Anyone cognisant of the

rudiments of ornithology, even if he had never seen or heard of a sparrow, would say at once if one were placed in his hand, from a glance at its beak, that it is a seed and vegetable feeder, just as he would say of the soft-billed birds that they are insectivorous. And now let me say something else which I have seen within the last few days, though it was no novelty to me, like the destruction of Apple blossoms. I saw a sparrow light on the shoot of a wall Rose, pick some aphides off, and feed a young one close by with them. Has the value of my eyes as witnesses risen in Mr. Witherspoon's estimation?

I have never denied or doubted that sparrows, and perhaps all birds, feed their young occasionally at least with insect or animal food. But, now look at the profit and loss view of the matter. The sparrow has stripped my Apple tree of blossom; he has also taken some aphides from my Rose tree, not stripped it by any means. The aphides will be as numerous as ever in a week. There will be no Apples this year, and no more blossom till next spring. Moreover, I could have removed the aphides myself if I had been anxious to do so. No earthly power can put the Apple blossom back on the tree.

As I said last week, we like to do what we can ourselves rather than leave it to Nature. We think we can do it with more discretion and more in accordance with our own particular views. As in thinning, so in the destruction of pests, Nature requires to be controlled. She may not be strong enough and so require help, or too strong and require to be repressed. I thought so yesterday morning, if I may use a homely illustration, when the man who came to clean my kitchen boiler said the pipes were choked and new ones must be put in, or the boiler might burst to the great danger of anyone near. I said "I think it must be done; it is unfortunately necessary that the cook should be occasionally 'blown up,' but—well, we like to do it ourselves. The operations of Nature are too violent and indiscriminate (I might be there myself!), and they must be controlled." He agreed with me.

But to return to our birds. As the graminivorous sparrow feeds its young occasionally with insect food, so the insectivorous birds will sometimes do considerable damage to soft fruit. The blackbird or thrush will eat impartially the slug and the Strawberry—the latter for choice, I fear. Starlings will eat Cherries; the blackcap warbler is very fond of Raspberries, so much so that he is locally called in some places the Raspberry eater; and, unkindest cut of all, the young robins of the year are certainly fond of Red Currants. What then? Does Mr. Witherspoon think that I am advocating the destruction of blackcaps and robins? Certainly not, this is not their natural food for the greater part of the year, nor will I spare the sparrow till his numbers are reasonably limited, because he takes a few aphides and caterpillars, which are not his natural food, during a month or so.

Man was put into the garden "to dress it and to keep it," and one of the prominent parts of his "keeping" I should think would be to recognise clearly the distinction between his friends and his foes, and not to encourage and harbour a number of graminivorous birds on purpose to keep down his insects, as I understand Mr. Witherspoon does, when other birds have been created and appointed for that very object.

It is well known that our highest authority on insect pests—Miss Ormerod—has declared against the sparrow. It is also generally known, I think, that the majority of insects and garden pests are winged in the perfect state, and celebrate their nuptials in the air; and that certain of our birds, the swallow and flycatcher tribes, spend their whole time in destroying them in the air, and (*pace* Mr. Witherspoon) do not "devour green food if within their reach."

Can the sparrow make up for his misdeeds in driving away the martin and appropriating his nest, by destroying a few dozen or score of caterpillars or grubs, when one parent insect devoured by the martin would represent so many more?

It is worthy of notice that the sparrow is getting worse; he did not to my knowledge, when I was a boy, destroy Gooseberry buds, pull off Primroses or Apple blossoms, or take martin's nests. I attribute his gradual growth in evil propensities entirely to his undue increase; and his increase to the doing away of sparrow clubs, and the prevalence in some parts of the general views of Mr. Witherspoon. It is also noticeable that it was soon after the time that sparrows had made martins much scarcer by driving them away that the present great increase of caterpillars on fruit trees commenced; but I make no charge where my eyes cannot prove it.

The sparrow is a parasite, not upon man's person but upon his property. Parasites upon other creatures' belongings are not unknown among birds, as witness the cuckoo, for instance. What is the use of the sparrow? I do not know; but then I do not know the use of certain other parasites. Parasites (as ichneumon flies) upon insects are no doubt meant to keep them down and prevent their undue increase. If sparrows are meant to keep down gardeners, then let the gardeners have fair play and fight for themselves. I object to the sparrow laying eggs upon me and eating me up; but Mr. Witherspoon need not fear extermination. The sparrow is smart, even in England, and no wonder that after a little education he has become smarter still among the Yankees. He will be a clever man who catches "the last one."—W. R. RAILLEM.

[Forty years ago the hordes of sparrows in a district denuded fruit bushes of their buds in spite of cotton (black and white), of soot and lime, and cats. They drove swallows and martins from their nests, and ruined yellow Crocuses, while in one particular instance an allotment holder had a rood of Wheat of fine promise; the sparrows devoured the whole of it, and the cottager had nothing but the straw for his winter store. They are gregarious, and need distributing. Our correspondent evidently has too many, and could spare some for Mr. Witherspoon.]

## MIDLAND COUNTIES PANSY SHOW AT TAMWORTH.

At the Exhibition, May 24th, there was a very fine display of blooms and the above date just suited the very early season, while the growers from Scotland were able to show well. Much interest was centred on the contest between the great growers from the north, especially in the class for forty-eight blooms of Fancy Pansies, dissimilar. There were five exhibits. Mr. A. Bailey, jun., florist, Sunderland, was placed first with excellent blooms of Beauty, a fine seedling; White Queen, very good; Evangeline, a rich flower of good form; Mrs. C. S. Scarse, Evelyn Bruce, A. H. Murray, Dr. Bostock, fine; William Mackie, James J. Irvine, Mrs. D. Johnstone, excellent; Tamworth Yellow, Mrs. J. Irvine, Bella Coutts, very fine; Maggie A. Scott, Archie Buchanan, Robert Jamieson, Nannie Scott, Walter Brown, Louise Weirter, Kate McArthur, Mrs. Train, Mrs. Mackie, Alexander Smith, Robert Lord, James Campbell, Miss Hudson, Norman McKenzie, Mrs. Thomas Ritchie, Edward Pollard, John Allen, excellent; William Allen, Mrs. Hugh Weir, very fine; Helen Patteson, James Simkins, a grand bloom; Mrs. Grossart, Wm. Archer, very fine; David Rennie, Neptune, white with a grand blotch; Duchess of Portland, Edith T. Crossley, Maggie McPhail, My Lady, Lord Hamilton, Lord Butc, seedlings, and others. Mr. John Smellie, florist, Bushey, Glasgow, was second with also a very fine stand, and a close competitor.

For twenty-four Fancy Pansies, dissimilar, Mr. Bailey was again first with David Rennie, Dr. Bostock, Maggie McPhail, Neptune, Wm. Archer, James Campbell, Mrs. S. C. Scarse, very fine; Betsy Kelly, Mrs. Train, fine; Donald Morrison, Mrs. Grosart, good; Mr. Lord, a new and very peculiar tint of colour, a grand blotch, with blue tinted margin to the lower petals, and blue violet top petals; Alexander Smith, Billy Johnstone, J. S. Irvine, White Queen, lilac-tinted top petals, with large solid blotch, and fine; James Simkins, extra fine; Archie Buchanan, Maggie A. Scott, Mrs. John Downie, and Edward Pollard, very fine. Mr. A. Lister, florist, Rothesay, second; and Mr. John Smellie, third. For twelve Fancy Pansies, open, Mr. Smellie was first; Mr. A. Campbell, Blantyre, second; Mr. Bailey, third.

The classes for Show Pansies were not so well filled, but for twenty-four Mr. Smellie was first, and Mr. Lister second; and for twelve blooms Mr. Lister was first; Mr. Campbell, second; Mr. Smellie, third. For six blooms of any one variety Mr. A. Irvine was first; Mr. Smellie, second; Mr. Bailey, third; and for twelve seedlings, own raising, Mr. Smellie was first; Mr. Lister, second; and Mr. J. D. Stuart, Malone, Belfast, third.

In the home counties' amateur classes Mr. Egginton, Wolverhampton, was first for twenty-four and eighteen Fancy Pansies, and Mr. A. C. Christic, Shifnal, another well-known grower, was second in each class, and Mr. T. M. Eglinton, third in each, with other growers fourth in each class.

For twelve and six Fancy Pansies Mr. George East, Leicester, was first, and Mr. W. B. Fowler, Tamworth, second; Mr. J. Haime, Longton, third, and Mr. John Draycott fourth; these winners in each class. There were also classes for Show Pansies and seedlings.

In the classes for amateurs who have never won a prize there were several exhibitors, Mr. H. Yeomans, Leicester, being first for twelve Fancies and second for six; Mr. Andrew Penson, Newport, Salop, second for twelve and first for six; and Mr. H. Jordan, Leicester, third in each class.

In the class for trade growers in the home counties Mr. William Sydenham, Tamworth, was first respectively for forty-eight and twenty-four blooms; and Messrs. Pope & Sons, Birmingham, second in each class. In these stands were the best varieties, and as especially fine were Emmie Stuart, Tamworth Yellow, Andrew Frater, Mrs. Train, Mrs. Wm. Sydenham, Mrs. J. D. Stuart, Mrs. Winstanley, Edward Pollard, Dr. Harrison (very fine), and Alexander Smellie. In the classes for twelve Fancy Pansies and six blooms of any one variety Mr. Sydenham was first and Messrs. Pope & Sons second, and Mr. Sydenham also staged a fine stand not for competition.

First-class certificates were awarded to the following seedling Fancy Pansies, three blooms of each.—Princess, creamy white, with a distinct even narrow margin of rosy crimson, quite even in the marking on each petal, solid blotch and fine form, exhibited by Mr. Campbell. To seedling Fancy Mrs. Spence, a very fine flower, exhibited by Mr. Andrew Irvine. To seedling Romeo, excellent, exhibited by Mr. J. Lister. To Marmion and Mrs. William Watson, two superb flowers, exhibited by Mr. J. Smellie. To Beauty, a grand flower of Donald Morrison type—a noble back row flower, exhibited by Mr. Bailey; and to Queen's Park Gem, superb blotch, the petals margined with creamy white, and a rich shade of blue, a grand flower, exhibited by Mr. Lister.

First-class certificates were also awarded to the following seedling Show Pansies:—John Walt, dark self, staged by Mr. Campbell; to W. H. Clark, a very fine yellow ground, exhibited by Mr. J. D. Stuart, Belfast; and to W. T. Bassett, dark self, by Mr. Lister.

Messrs. Dobbie & Son had an extensive show of Violas, and a first-class certificate was awarded for Lillie Langtry.

It was freely acknowledged to be a splendid exhibition of Pansies, and there was a large attendance, the Exhibition having been opened by the Mayor of Tamworth.

## WAKEFIELD AMATEUR TULIP SHOW.—MAY 22ND, 23RD.

AFTER passing through the inevitable vicissitudes of fashion, the florists' Tulip is now showing a decided reaction. We are informed that during the last two or three years there has been a greater demand for

standard varieties than stockholders are willing to part with. In no part of the United Kingdom has the fancy held on so tenaciously to the old love for this flower than has been the case in and around the city of Wakefield. Some of the growers pride themselves on the fact that as descendants of families which for three and four successive generations have grown and regularly exhibited their flowers.

It is without doubt a rare treat to be in at the judging of the flowers. The system of judging adopted gives the exhibitors a chance of thoroughly discussing and criticising the awards. As each class is adjudicated upon the winning flowers are taken into another room, and in their order of merit with their names are entered into the Secretary's book, and thus valuable and interesting record of the winners has been kept during the fifty odd years the Society has been in existence. The exhibitors sitting around the table, every interesting point and detail in connection with the flowers are freely discussed, and a novice would be amazed to find so much friendly rivalry and enjoyment derived by those who are placed low down on the list of winners, in the fact that the beauty and good points of a flower are more to them than the actual money value of the prizes.

Some of the exhibitors grow large beds containing thousands of plants, and the displays of bloom attract many visitors to view a short-lived but wonderfully gorgeous sight. The merits of the flowers can be discussed with the cultivator. It may be that he is a Knight of St. Crispin, or has for his coat of arms a "Goose and Shears;" and few of them but are able between whiles to hold a discussion on politics or give a lesson in political economy. One knight of the lapstone maketh to himself a very wilderness of Tulips, wherein during the blooming period he may at all times be found, including worktime, bedtime, and Sundays, mostly on his knees, searching for the budding charms of his Queen of the May, or lamenting the faded beauty of his Heroine. It may be that Mary Jackson's and Annie McGregor's toilet in matters of feathers and paint have not shown their usual good taste; yet so confident is he that on points of form and clearness of complexion he is ready to stake his throne (cobbler's stool) and sceptre (hammer and lapstone) for the remainder of the year (they are no use to him during the blooming period).

Of course, when the exhibition day comes round and the Judges' fiat has gone forth, everyone takes both their victories and defeats in the best possible spirit, yet vow vengeance on each other in the year to come. This year the awards are as below.

**RECTIFIED TULIPS**, pan of six.—First, Mr. William Mellor, with Sir J. Paxton, Lord F. Cavendish, George Hardwick, Mary Jackson, Industry, and Dauntless. Second, Mr. Edward Lister, with Sir J. Paxton, George Hardwick, Queen of the May, Parker's King, Annie McGregor, Mrs. Lee. Third, Mr. George Gill, with Sir J. Paxton, Garibaldi, Queen of the May, Sylvester, Mabel, Heroine. Fourth, Mr. A. Moorhouse. Fifth, Mr. W. Calvert. Sixth, Mr. H. Brown. Seventh, Mr. J. Hardwick. Eighth, Mr. Thomas Maddock.

**SIX BREEDER TULIPS**.—First, Mr. A. Moorhouse, with Sir J. Paxton, Dr. Hardy, Talisman, Bridesmaid, Mabel, Miss Burdett Coutts. Second, Mr. W. Calvert, with Sir J. Paxton, Miss Collins, Richard Yates, Duchess of Sutherland, Industry, Sylvester. Third, Mr. W. Mellor, with Sir J. Paxton, Bridesmaid, Hardwick, Talisman, Rose Hill, Annie McGregor. Fourth, Mr. George Gill. Fifth, Mr. George Hardwick. Sixth, Mr. Edward Lister.

**THREE BREEDER TULIPS**.—First, Mr. W. Mellor, with Sir J. Paxton, Miss B. Coutts, Hardwick. Second, Mr. A. Moorhouse, with Dr. Hardy, Bridesmaid, Miss B. Coutts. Third, Mr. W. Calvert, with Sir J. Paxton, Hepworth, Agnes Strickland. Fourth, Mr. Geo. Gill. Fifth, Mr. Ed. Lister. Sixth, Mr. T. Maddock. Seventh, Mr. J. Lister. Eighth, Mr. H. Brown.

**FLAMED BIZARRE TULIP**.—First and second, Mr. W. Mellor, Dr. Hardy, and Sir J. Paxton. Third, Mr. E. Lister, with Sir J. Paxton.

**FEATHER BIZARRES**.—First, Mr. A. Moorhouse, with Masterpiece. Second, Mr. W. Mellor, Sir J. Paxton. Third, Mr. Geo. Gill, unknown.

**FLAMED BYBLÆMENS**.—First and second, Mr. W. Mellor, with Talisman and Lord Denman. Third, Mr. A. Moorhouse, Queen of May.

**FEATHERED BYBLÆMENS**.—First, Mr. A. Moorhouse, with Bessie. Second and third, Mr. W. Mellor, Queen of May and Geo. Hardwick.

**FEATHERED ROSES**.—First, Mr. W. Mellor, with Mrs. Lee. Second, Mr. T. Maddock, Aglaia. Third, Mr. W. Mellor, Mrs. Lee.

**BIZARRE BREEDERS**.—First, Mr. A. Moorhouse, with Dr. Hardy. Second and third, Mr. W. Mellor, Sir J. Paxton.

**BYBLÆMEN BREEDERS**.—First, Mr. Geo. Gill, with Geo. Hardwick. Second, Mr. A. Moorhouse, Bridesmaid. Third, Mr. J. Hardwick, Sylvester.

**ROSE BREEDERS**.—First and second, Mr. Geo. Gill, with Thos. Parker. Third, Mr. W. Mellor, Industry.

**PREMIER FLOWERS**.—Flamed, Mr. Wm. Mellor, with Mary Jackson. Feathered, Mr. W. Mellor, Lord F. Cavendish. Breeder, Mr. W. Calvert, Miss Collins.

#### TRADE CATALOGUES RECEIVED.

William Bull, King's Road, Chelsea.—*New and Rare Plants and Orchids.*

Eden, Fisher & Co., 50, Lombard Street, E.C.—*The Country Gentleman's Catalogue.*

Friedrich Adolph Haage, jun., Erfurt, Germany.—*Catalogue of Cacti.*

J. Laing & Sons, Forest Hill, S.E.—*Tuberous Begonias.*

J. Peed & Sons, Roupell Park Nurseries, Norwood Road.—*Stove and Greenhouse Plants and Caladiums.*

#### HARDY FRUIT GARDEN.

**General Summer Treatment.**—The process of disbudding will have ridded fruit trees of much useless, gross, and unnecessary wood. If not removed this would have crowded the legitimate growths wanted to furnish the trees with a sufficient quantity of wood both for future bearing and extension. Disbudding is now impracticable in cases where removal of wood is needed, except with gross soft growths that start away from old wood. This can easily be rubbed off at any time if not wanted, but woody growths must be cut off with the knife. Gross, attenuated, or ill-placed shoots are not always apparent at the early examinations of the trees, and it is well throughout the season to keep watch on the advancing growths during the frequent visits and close scrutinies made. Removals of growth effected at intervals and in small quantities are better for the trees. Thinning wholesale at any time is opposed to their well being.

**Securing Growth.**—The proper securing of reserved shoots on wall trees must be attended to, not only to preserve them from injury by breakage from wind or other causes, but to prevent them shading each other unduly, as well as to preserve an equal balance of neatly trained growths. Very close or tight tying or nailing-in near the extremities is not essential; but it is well to incline the wood retained in the direction it will ultimately take.

**Thinning Fruit.**—Remove more fruit from crowded trusses and clusters of Strawberries, Plums, Apples, Pears, and Cherries, as soon as the majority reach the size of Hazel Nuts. Fruits not swelling on any trees owing to imperfect fertilisation clear away as soon as possible. Fine examples can only be obtained by judicious thinning. For general purposes more fruit may be left with advantage, but do not overburden the trees, the perfecting of a heavy crop being a great strain upon them, and likely, if overdone, to jeopardise the following year's chances. Green Gooseberries may be freely thinned for culinary purposes, enough being retained if desired for swelling to a large size and ripening as dessert fruit.

**Netting Strawberries.**—Strawberries have been much benefited by the recent rains, and with the aid of liquid manure or the nutriment from the mulching material the fruits are now swelling well, and will quickly change colour. Birds often then become troublesome, spoiling the best fruits. To preserve these from attack cover the beds with nets. Affix forked stakes at the ends of rows and at intervals along them to support strong laths, over which nets of sufficiently close mesh can be thrown clear of the plants. Make the ends and sides secure to prevent the entrance of birds underneath, and the fruit will be safe. Tared string strained tightly to stakes fulfils the same purpose as laths laid across, and is neater in appearance. In some cases the nets laid over the plants are sufficient.

**Summer Pruning.**—The breastwood or foreright shoots on wall trees, pyramids, espaliers, and other forms of restricted trees should during the following weeks be dealt with. It is best to commence pinching when four to six full sized lower leaves have been formed. These are then fully capable of elaborating the sap for feeding the basal buds, which then soon become converted into fruit buds. This early season the leaves referred to are, or fast becoming, full sized. Commence with reducing the shoots belonging to Apples and Pears, dealing first with the upper and strongest parts of trees. The opportunity is then given of weaker shoots extending and strengthening a short time longer. Summer pruning is always best done progressively, no check then being given to trees by the removal of large quantities of wood and foliage at one time. If the result of the summer pruning has such an effect that it pushes the lower buds of the shortened shoots into growth during the current season it fails of its object, which should be rather that of feeding the buds in question by concentrating the sap upon them, so that they may form fruiting spurs. Take care when counting the proper number of leaves to retain, not to include the small basal leaves. In a short time fresh growths will push from the extremities, and when the first formed leaf on each has developed to nearly its full size shorten the growth just above it, continuing to do this as often as fresh shoots form.

**Plums and Cherries.**—The shoots on wall trees which are not laid in as extensions or to fill up vacancies are shortened to the fourth or fifth leaves, which in these fruits include the small basal leaves. If space does not allow of reserved shoots being properly laid in without crowding, stop them also near the point where they intercross others. Many of them, however, could be trained full length over bare portions of main branches. Plum and Cherry shoots are often infested with aphides at the extremities. Summer pruning will rid the trees of much of this, but those shoots which are infested and there is no intention of shortening them should be dipped in some insecticide.

**Red and White Currants.**—These often have the extreme points of new growth seriously infested with aphides. They are more troublesome to trees where the growth is checked by dryness at the roots or the soil lacks nutriment. At the present time such infested tips of shoots may be promptly removed and burnt, leaving three pairs

of full-grown leaves. Where the roots are suspected of being largely in a dry medium, which is often the case when trees trained to walls or bushes in the open have existed long on one site, means must be taken to moisten the ground, first with copious supplies of clear water, afterwards with liquid manure, followed by a mulching of manure. This will be advantageous to the rapid swelling of the bunches of fruit, and to the production of clean healthy growth.

**Gooseberries.**—Trained on restrictive methods in any position, these will now need the summer shoots shortening in the same manner as Currants. Aphides are often very troublesome at the points of Gooseberry shoots, being produced by the same causes which favour their presence on other trees. Pruning the side shoots will clear the trees to a large extent, any infested shoots left dust with tobacco powder. Improve the growth by applying water and liquid manure. Free-grown bushes should have gross and crowded wood thinned out. Many of the branches as they are cleared of fruit may be cut out entirely to make room for new wood of the current year.

#### FRUIT FORCING.

**Pines.**—*Potting Suckers.*—The early-fruited plants of Queens and Enville will afford strong suckers as they finish, and if these be taken during the first fortnight of June in sufficient quantity to maintain the stock equal to the demand for fruit and are started at once, they will give plants for fruiting about this time next year, following those started into fruit in the spring. The treatment then given to suckers will answer for these, only they will require more careful shading and frequent attention to damping.

*Spring-potted Suckers.*—The strongest of those potted last March will be in the pots in which they are to fruit; if not, they must be shifted without further delay. To allow them to become root-bound is debilitating and detrimental to them. Recently potted plants should have a steady bottom heat of 85° to 90°, be thoroughly watered after potting if the soil be dry.

*Ventilating, Watering, Syringing, and Shading.*—Young plants are making rapid progress, and should be allowed sufficient space for development. Ventilate early in the day at 75° to 80° to dissipate moisture from the leaves before it is powerfully acted upon by the sun. That is the way to secure sturdy plants as well as avoid scorching. Examine the plants twice a week for watering, not giving any until it is needed, and then a thorough soaking with tepid liquid manure, being careful not to apply it too strong. Discontinue shading succession plants so soon as they will bear the sun safely, but fruiting plants with the crowns in close proximity to the glass will require slight shade. Syringe the plants on bright afternoons, and otherwise maintain a genial condition of the atmosphere. Avoid, however, much moisture in dull weather, for it only tends to cause attenuated and soft growth. Where water remains in the axils of the leaves syringing is not so much required, and in watering pour the water well up the plants, but not into their centres.

*Plants for Winter Fruiting.*—The strongest of the plants ought now to be showing fruit, if not, means must be taken to effect it. The plants should be brought together and subjected to a comparative rest for a month or six weeks, lowering the heat at the roots to 75°, maintaining a free circulation of air about the plants in favourable weather. Ventilate at 75°, and allow the heat to fall to that point before closing the house. Only employ artificial heat to prevent the temperature falling below 60° at night. Do not withhold water altogether, but when a plant becomes dry afford it liberally. Suckers that were wintered in 7 or 8-inch pots, and repotted this spring, must be kept growing until the pots are well filled with roots, at which time, if considered necessary, they may be subjected to the same treatment as advised for the larger plants, and they will then give a successional supply of fruit.

*Fruit Ripening.*—Cease syringing the plants and lessen the supply of moisture, but the watering at the roots must be sufficient to prevent distress in the foliage. Ventilate when circumstances permit with a view to improve the quality of the fruit, but do not allow the temperature to fall below 80° in the day, and apply fire heat to maintain a night temperature of 70° to 75°. Queen, Enville, and Providence Pines started into fruit early in February will ripen this month, coming in about a month before Smooth-leaved Cayenne and Charlotte Rothschild started at the same time and under similar conditions. These afford a supply of fruit in succession, and it may be still further extended by removing some of the plants with the fruits to a cooler house. The heat should be maintained at 85° to 90° at the roots.

**Figs.**—*Early Forced Trees.*—Trees in pots must be mulched with rich material, and receive generous treatment to enable them to swell the second crop of fruit, supplying liquid manure once or twice a day. Planted out trees require water once or twice a week, according to the extent of the rooting area, affording liquid manure or top-dressings of rich material in accordance with the needs of the trees. The second crop should be thinned before the fruit is the size of Walnuts, and in thinning reserve the largest fruits at the base of the shoots. Syringe twice a day to keep red spider in check, and, if necessary, apply an insecticide, removing scale with a brush, taking care not to damage the young fruit, or it will be seriously disfigured.

*Succession Houses.*—When the fruit gives the least indication of ripening, syringing the trees must be discontinued. If red spider attack the foliage the fruit should be gathered closely and a good syringing given, which will not injure the fruit provided it is done early on a fine day. A free circulation of warm dry air should be afforded, which is essential to high quality, but the atmosphere must not be arid or the foliage will

suffer, and moderate moisture will not damage the fruit provided a circulation of air is maintained and the Figs not wetted. Afford the fruit the benefit of all the light practicable, tying-in and regulating the shoots by thinning and stopping. Trees swelling their crops will require syringing twice a day, copious supplies of water or liquid manure at the roots, and a genial atmosphere.

*Young Trees in Pots for Next Year's Early Forcing.*—These should be of varieties that afford good results in their first crops, as St. John's, Angélique, Early Violet (which have small fruit), Brown Turkey and White Marseilles—the two best Figs for general culture, and they must not be neglected or disappointment is inevitable. They must have all the light possible and be kept as near the glass as practicable without touching, so as to secure sturdy well ripened growth, and pinching should not be practised to a late period, otherwise the shoots will not mature sufficiently to carry a first crop of fruit. The foliage must be kept clean, and liquid manure supplied so as to secure stout but not gross growth. When the growth is complete the trees may be stood outdoors to induce rest, but the wood should be well ripened previously, and to be of use for early forcing it must be matured early.

**Peaches and Nectarines.**—*Early Forced Trees.*—The fruit being all gathered from the very early varieties the wood on which the Peaches and Nectarines have been borne and not being extensions should be cut out. This will admit more light and air to the shoots which are to afford fruit next season, and allow of the better cleansing of the trees, which should have a good washing with water from the syringe or garden engine, or if insects have obtained a footing they must be destroyed by some approved insecticide. Daily syringing will be necessary to keep the foliage clean. Admit air freely so as to maintain the foliage in good condition as long as practicable. The roof lights should not be removed until the wood is matured and the buds fairly formed, but this matter must be attended to at no distant period with a view to prevent overdevelopment of the buds and early casting of the foliage. Supply water or liquid manure to the roots so as to maintain the soil in a thoroughly moist condition, and a light mulching will keep the roots active at the surface provided it is kept moist.

*Second Early House.*—Admit plenty of air to the ripening fruit in the daytime, and at night also if a prolonged succession of fruit is required. Remove any leaves that shade the fruit too much, so that it may colour and ripen evenly. No artificial heat will now be necessary except in dull weather, when a little may be employed to permit a free circulation of air where the fruit is ripening, and syringing must cease with the first indication of ripening. Maintain a genial atmosphere by damping available surfaces when they become dry. The borders must be kept in a thoroughly moist state, and be supplied with nourishment after the fruit is gathered, so as to keep the foliage healthy as long as possible. Cut away the wood which carried the fruit to the shoot at the base for next year's fruiting after the crop is cleared, excepting those needful for the extension of the trees. If the trees are too full of wood thin well so as to admit light and air to the shoots, and thereby ensure the thorough ripening of the wood.

*Succession Houses.*—The trees will need attention in regulating the growth, extensions being trained in their full length where space admits, and pinching laterals to each joint of growth as made. Shoots trained in from last year's extensions at 12 to 15 inches apart may be stopped at those lengths, also shoots from the base of those now bearing if they are likely to exceed that extent of growth, keeping the laterals well pinched. Growths retained to attract the sap to the fruit will require pinching at each leaf after the first stopping at three good leaves. The fruit taking its last swelling should be well exposed to the light, drawing the leaves aside, shortening or removing them, and raising the depending fruits on laths with their apexes to the light. Early ventilation saves the foliage from scorching, and early closing with plenty of moisture accelerates the swelling of the fruits. Fruit stoning must not be hurried, 60° to 65° being sufficiently high by artificial means in the daytime, and the temperature may fall to 55° at night. When the fruit has stoned the final thinning should be effected without delay. Keep the trees well supplied with water or liquid manure at the roots, and the foliage clean and healthy by syringing.

*Late Houses.*—Disbudding will now be completed, and the tying-in of the young shoots attended to. Thinning the fruit also will be finished, no more fruits being left for the crop than a few to meet casualties in stoning. Early and free ventilation on all favourable occasions will be the order of the day, along with early closing and syringing morning and afternoon. If aphides appear destroy them by repeated moderate fumigation when the foliage is dry. Red spider and thrips have little chance where syringing is properly done. If mildew appear dust with flowers of sulphur, rubbing it on the white specks if any are seen on the fruit, or syringe with a solution of softsoap, 2 ozs. to the gallon of water, with a tablespoonful of sulphur added.

#### THE FLOWER GARDEN.

**Late Planting.**—Some soils have become so very dry and difficult to remoisten, and rains have not been nearly so heavy in some parts as in others, and it is possible that many flower beds and borders, more especially the odd corners, are in a far too dry state for the reception of plants. To make matters worse, the plants that have to be put out in the positions last filled are of poor quality—the best have been used first. What are wanted, therefore, are conditions favourable to a good start rather than otherwise, and the makeshift arrangements may then eventually eclipse some of the more formally arranged beds. Dry soils ought to have one or two thorough soakings of water before the planting

is done, as it will be next to impossible to properly moisten them afterwards. Odd corners should have a liberal dressing of either decayed manure, thoroughly decomposed vegetable refuse, including lawn grass and leaves, or leaf soil forked-in.

In soils thus lightened and enriched quite a variety of greenhouse plants might be planted with the best results. Plants of Abutilons, Zonal Pelargoniums, Plumbago capensis, Heliotropes, Fuchsias, fibrous and tuberous-rooted Begonias, with Nicotiana, herbaceous Lobelias, Celosias, Hedychiums, Erythras, Lilium auratum, Cannas, Palms, variegated Maize, Marguerites, and such like mixed and arranged according to their respective heights and habits of growth, and given the benefit of a fairly rich root run, would soon be effective, remaining so to the end of the season. Plants being scarce, quite large old Zonal Pelargoniums may be used for filling beds, but they need to be planted in a sloping direction, and kept evenly spread out and pegged down. All large as well as small plants should be in a thoroughly moist state at the roots when turned, and where the soil is somewhat sour and unoccupied with roots much of this ought to be forked away prior to planting. Make the fresh soil somewhat firm about them, and plant deep enough to admit of a basin being formed for holding water about each stem. For the first three weeks or more they must be kept well supplied with water, as should the old ball of soil and roots once become dust-dry before strong fresh roots have spread into the new soil there will be no remoistening it, and the plants will do badly accordingly. If Iresines, Coleuses, Alternantheras, and such like very tender plants are planted on or about June 10th, that will be quite early enough for very many places.

**Annuals.**—Those sown in the open did not germinate well when they were expected to, but many have started since the change in the weather. As a rule, the majority are grown far too thickly. When each plant receives good room all branch strongly and form finer flowers, and give a much longer succession accordingly. Especially ought Poppies to be freely thinned out. Left as thickly as they come up the display will be very fleeting indeed. Thin out the larger Japanese and French varieties to about 1 foot asunder, and remove the seed pods as fast as they form, thereby considerably prolonging the display. The popular Shirley Poppies should be thinned to about 9 inches apart, another 3 inches being none too much on good soils. Cut the flowers freely for vases when quite young, and gather what seed pods form. If more seed is sown on moist ground at once a good autumn display will most probably be had. Mignonette again ought to have plenty of room. Isolated plants always give much the finest and the longest succession of flower spikes; therefore thin to about 1 foot apart.

Candytufts, Eschscholtzias, Love-lies-bleeding, Nasturtiums, Cornflowers, Marigolds, Chrysanthemums, Convolvulus, all branch or spread considerably if given good room, and should be thinned to not less than 10 inches asunder, while if they are sown in patches reduce the number of plants to five or six in each. Clarkias, Coreopsis, Godetias, Linaria, Malope, Nemophila, Virginia Stock, and Eranthemums as a rule do not spread greatly, and may therefore be left rather more thickly in the lines or patches. If any transplanting is done let it be as much as possible with a trowel, outside plants being moved with a little ball of soil about the roots, taken straight to where they are to be replanted, and watered directly they are in their fresh quarters. Ornamental Grasses ought certainly to be freely thinned out, and these may also be transplanted. Sunflowers should be thinned out according to the habit of the varieties. Those which naturally grow tall should be thinned to about 3 feet apart, and they will then branch strongly and flower grandly. The miniature variety may be left much closer together, these being planted or thinned to about 1 foot apart.

**Sweet Peas.**—These have come up thickly, and were left to grow unthinned, the display is not likely to last long. In most cases it is now too late to thin out, and more seed should be sown at once if flowers are wanted late in the summer or autumn. When grown thinly, or not less than 4 inches apart in the rows, and better still if planted out from pots in patches of about five plants and well isolated, ordinary Pea sticks being placed to the plants in each case, they grow and branch vigorously. Being watered freely in hot dry weather, and the bulk of the flowers cut or the seed pods removed frequently, these well-treated Peas will usually continue to produce fine flowers till frost intervene.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### PAINTING HIVES.

A CORRESPONDENT asks if there is any objection to painting hives inside. Coal tar is better adapted for the inside of hives than ordinary oil paints. It (or creosote) penetrates the pores of the wood without closing them as oil paints do, and evaporation through the walls of the hive is desirable for the health and preservation of bees. Painting the inside of hives and solid floors would be destructive to bees during winter. There is nothing else so fatal to bees as damp floors. For the purpose of preserving my double-cased hives from decay I was compelled to tar them inside, and it did no injury whatever to the bees. The most serviceable and

economical hives are single-cased ones, protected outside by some non-conducting material that allows the perspiration to pass off. No hive should have its walls thicker than five-eighths of an inch, and yellow pine is the best material to use in making them.

#### SEALED COVERS OR ABSORBENTS.

These have been engaging the minds of bee-keepers of this country and America. Tarred paper was recommended by one "expert," but proved, as I anticipated, a failure. It is true some cases of success are reported, but the majority are pronounced failures. Neither sealed covers nor absorbents are proper materials to use. Non-conducting but porous material, as stated above, will defy the harshest winter ever experienced in this country. A Hull lady bee-keeper, but still a novice, acted wisely in pricking holes in the enamelled cover of a hive constructed according to the wisdom of our modern sages and bee-keepers.

#### TWO QUEENS IN ONE HIVE.

Much nonsense has been written in connection with this ancient practice—as queenless and eggless hives raising queens, shifting eggs from one cell to another, and queens depositing eggs in royal cells. The case that occurred in my apiary (July, 1892) was in itself sufficient without further evidence (even if there had been no other) to prove that there is design in fertile workers being in the hive with an unfertilised queen. We have repeatedly had queens twelve weeks old before they mated. This gives ample time for the progeny of fertile workers to be fully matured and fit for mating should there be no other drones in the neighbourhood. This wise provision of Nature has mystified bee-keepers and encouraged error to a great extent, but has within our knowledge in not a few cases saved the colony, whose fate would otherwise have been doomed.

#### FEEDING AND SUPERING.

Now is the time to be watchful that stocks do not suffer by egg-eating and brood drawing. Two ozs. to 4 ozs. of dissolved sugar every night during the barren honey season will keep things straight, and tin scoops are the best feeders. Supers should now be put on all hives, whether intended as swarmers or non-swarmers.

#### SPARROWS AND BEES.

Sparrows are fond of the immature grubs of drones. Owing to this taste and the sparrow's tameness I was deprived of a fine specimen of a drone reared in a queen cell. When opening some cells I observed a peculiar formation on one of the drones, being finer in appearance, and showing signs of alteration of structure of the legs. I laid it down unprotected until I had adjusted the hive, but the "scoundrel sparrow" swallowed him, and so I was deprived of making an interesting examination.—A LANARKSHIRE BEE-KEEPER.

••All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Tomato Disease (E. H. R.).**—The fragment of leaf sent is wholly insufficient. The paper had deprived it of moisture, and the letter stamp smashed the tissue into fragments. If you will send one or two entire leaves and the points of any affected shoots in a small box, to reach us on Saturday if possible, they will be subjected to careful examination.

**Royal Horticultural Society's Meetings (J. A.).**—Meetings will be held on June 6th and 20th; July 11th (at Chiswick), and 25th; August 8th and 29th, the last-named in connection with the great show in the Agricultural Hall, Islington. Those dates will perhaps be

IT would appear that the days for sensational prices are over, never to return. Nor, personally, do I much regret this so long as the returns are remunerative. Nothing is more demoralising to the market grower than the sudden fluctuations consequent upon a short scarcity of any particular kind of perishable commodity. For instance, when forced Strawberries were quoted at say 1s. per oz., and the next day dropped to about half that figure, this vexed the grower far more than if the commencement had been nearer 10s. per lb., and they remained longer about that price. After learning that certain fruits are in great demand and the prices extremely high, the grower naturally reckons upon at least a short run of good returns, only to find that nothing of the sort is likely to occur. Unless he has had some previous experience and knows better, the first conclusion arrived at is that there is "something rotten in the state of Denmark," or in other words, that the salesman he patronises is little short of being a swindler. This latter conclusion is, I am afraid, too often indulged in by disappointed growers; more especially by those without much experience to guide them in their decision.

Because the prices returned do not exactly agree with those just previously obtained, or do not correspond closely with what the grower thinks ought to prevail, salesmen are forthwith "called over the coals." But are they all rogues? Are any of the well established salesmen in Covent Garden, or other leading markets, swindlers? I reply that no one dare impugn their business practices, and will go further and assert that they do their best for their clients, and not unfrequently at a loss to themselves. In order to be able to speak with any authority in the matter of either condemning or praising the salesmen, senders should attend the markets occasionally and judge for themselves what is going on. According to my experience, gleaned at all hours in Covent Garden, and all night and day long in the Spitalfields and Borough Markets, prices vary surprisingly in one morning. At the outset good prices may prevail, and a short time after, for the business is transacted very quickly, the same class of goods can scarcely be given away. Naturally this lowers the average materially and makes it very hard for the salesmen to regulate the returns to the senders. That the best of them do the latter honestly and fairly there is no disputing. When they get good clients they like to keep them on the books, and this would be impossible if trickery was resorted to often, the sender easily testing the honesty of one salesman by consigning similar packages to other salesmen in the same market.

Whether the prices shall be good or not is largely determined by the sender, always supposing there is no great glut and slack demand on any particular morning. If no pains are taken in sorting or grading the wares, or in the packing of the same, low prices are almost inevitable. Mixing up what should be sorted into firsts and seconds is a senseless proceeding, as it invariably results in either medium or low prices being returned for the lot. Take Peaches for instance. If the very best—that is to say, large, highly coloured, sound fruit—are placed in one package and the second quality in another, 18s. per dozen may be returned for the former and 6s. for the latter, this bringing the whole up to the respectable average of 12s. per dozen, whereas if all had been mixed the average would be nearer 8s. per dozen, with the risk of still lower figures being

reached. Senders should also bear in mind that dead ripe fruit travels and keeps badly, and then salesmen cannot possibly obtain high prices; but on the contrary, seeing that they are more often thrown away than sold, the chances are a few over-ripe or damaged fruit will bring the average down very low indeed. Inferior fruit again is altogether out of place in high-class markets, and not unfrequently is either given away or sold at a loss. The senders, not the salesmen, are to blame for these occurrences. In the first place the former—that is to say, the grower—should strive to grow superior produce as much as possible, a comparatively light crop of extra fine fruit paying well at all times, while heavy crops of inferior fruit may not pay for gathering and sending even. Let the Channel Islanders have a monopoly of the markets as far as inferior Grapes are concerned, while foreigners who think to swamp English growers with various other kinds of fruit can easily be taught a lesson if only the latter could be persuaded to place nothing but the best against them. In each and every case the greatest pains, this not necessarily or advisedly amounting to coddling, should be taken with the packing, faulty packing quite spoiling the averages in many cases. "Topping up," or putting a few good fruit on rubbish, deceives nobody other than "greenhorns."

Private gardeners for many years past have consigned much surplus produce to the markets, and it is this class of growers that have suffered most from the general reduction in prices. Whatever may be said or thought to the contrary they are, I maintain, quite at a disadvantage with us wholesale or professional market growers. Not only have they as a rule an inferior—that is to say, an unsuitable class of houses to deal with, but they are also heavily handicapped in various other ways. Market growers have large, well heated, properly glazed structures, wholly or principally devoted to the purpose for which they are constructed, and are at liberty to send the best as well as the inferior produce to the markets. They send large and good consignments regularly, and it is not in human nature for salesmen to be other than partial to them. I mean partial in this sense—if any favour is shown to any class of senders it must be to those who are the best consigners and make fewer mistakes in sorting and sending. Private gardeners as a rule are not in a position to send other than in a fitful fashion, and more often than not the best samples have to go to the tables of the owners, and yet the seconds are expected to realise the highest prices in the markets.

Complaints are sometimes made of the incorrectness of the market quotations given every week in the different horticultural papers, and in some few cases, but only very few, is there some cause for grumbling. As far as my experience goes the figures given are most trustworthy, and so they are to others who have had similar experience of markets and their fluctuations. A fair average is struck, the very lowest and a few extremely high figures not being given. Moderate as are the quotations they are yet not unfrequently higher than the returns, and an explanation of this fact will be gathered from my preceding remarks.

A favourite practice of some owners of gardens is to visit some of the leading shops in Covent Garden Market as well as those in the more fashionable parts of the Metropolis, and there price different kinds of home-grown fruit on sale. Because somewhat high prices are asked they jump to the conclusion that their surplus produce ought to realise equally good money, quite overlooking the fact that there is a great difference between wholesale and retail prices, high rents, probable losses and other considerations also largely affecting the case. Nor are owners of gardens, or indeed many gardeners, capable of properly comparing what they have on their trees or Vines with what they see in a large shop. They are apt to imagine that their "geese are all swans," or, in other words, they very much over-rate their own produce. Let them send their best to a large shop and recognise it afterwards if they can. It is astonishing how much of the fruit that is taken either to a show or

a large shop where much other fruit is placed alongside seems to lose in size, and what a grower may think extra fine would perhaps be considered only moderately good by salesmen and fruiterers. My advice, therefore, to growers in a small way is to accept the quotations given as correct, and be also guided by them when fixing the prices of anything sold locally. I would also strongly advise private growers to sell as much as possible of their second-rate produce in the locality where it is grown, for it is very certain it does not pay nearly so well to consign it to Covent Garden or other important centres.—MARKET GROWER.

### OTHER LANDS.

IN resuming this subject, we may state that California and Oregon, together with Washington and Nevada, form the Pacific States, or those lying between the outer range of the Rocky Mountains system and the Pacific Ocean. This range bears the name of "the Sierras" in California and "the Cascades" in Oregon. Owing to the interposition of these mountains, the Pacific Slope enjoys an immunity from the severe cold and blizzards which afflict the prairie States to the east, while a warm current, similar to our Gulf Stream, sweeping round from the direction of Japan, appreciably tempers the climate. Hence places on the Pacific Slope have a much higher average temperature and a more equable climate than those in the Eastern States lying upon the same latitude, just as Edinburgh differs in these respects from St. Petersburg or Moscow. Not more than once in a generation does snow fall upon the lowlands of Northern California, though it is more frequent in Oregon. Oregon, like California, can boast of having several zones of climate, in consequence of the Cascade range dividing her into two geographically distinct portions. The maritime or western portion enjoys an insular climate, somewhat like our own, while that of the tra-montane district is more continental and extreme. It is intelligible, then, that as the capacities of Oregon come to be better understood, California will not seem to possess such an extraordinary advantage over her sister State, whose development has received no stimulation from the gold fever. This has given a sort of prematurity to everything about California, and a spirit of boastfulness and speculation to her population.

The State of Washington across the Columbia River, the northern boundary of Oregon, came very near to forming part of the Canadian Dominion. Fifty years ago, when the delimitation of the frontier was in discussion between the English and American governments, the line of the Columbia was proposed, and it looked as if the suggestion would be accepted, but the gorge of the Jefferson Bricks of that day rose at this concession to the "blasted Britisher," and the journals took to inflaming public opinion in the United States with the alliterative catch word "fifty-four forty (*i.e.*, degree of latitude), or fight." It being a period when the colonies were at a discount, and the British Lion was not feeling particularly land-hungry, Uncle Sam managed to get the frontier line fixed at several degrees north of Columbia, and thus much territory was yielded by England which now is included in the younger Western States. It was over much of this country that the Hudson Bay Company possessed the right of trading and trapping, and near Portland in Oregon, at a place called Astoria, stood one of their forts. In books, now neglected for works on more newly opened lands, we read of the wild life which went on round these old trading stations, such as would shock the ears of Exeter Hall, and drive Mr. Stead into hysterics. When we learn, however, that what with the consequences of exposure, the perils from Indians, and the accidents peculiar to their calling, the average of life among the trappers was only three years, we cannot be astonished at their recklessness. It seems scarcely rational in those who sit at home at ease to complain of the imperfections of men who do the rough and dirty work of Society in first penetrating the wilderness.

Similarly as Washington missed falling within the domain of John Bull, so, a few years later, at the time of the war between the United States and Mexico in 1846, England lost the opportunity of adding California and Oregon to her possessions. The story is still told of the way in which a Yankee skipper hurried to hoist the Star and Stripes in Southern California, and thus neutralised any claims England might prefer by virtue of the visit of Vancouver to the coast a century ago, or by reason of the acts of the Hudson Bay Company. Had England been keenly alive to her own interests, she might, previously to the Mexican War, have purchased the nominal rights of Mexico over California for very little, when the most agreeable lands in the temperate zone of the northern hemisphere would have passed under her flag in addition to those of the southern.

The whole of the Pacific slope is by nature isolated from the rest of the United States, and until connected with them by the formation of the Central Pacific Railway in 1869 the spirit of its population was by force of circumstances self-centred and sectional. It would not have been difficult, therefore, for England, had she been quick in annexing this territory sixty years ago, to consolidate her power along this coast as far as British Columbia, and shut the United States out from the Pacific Ocean. The millennium is as far off as ever, and time will show whether or not it was judicious of England to forego the advantage of excluding American influence from these waters. Americans cannot accuse England of having pushed her opportunities to the uttermost in this matter, or in abstaining from allying herself with the Confederate States during the War of Secession, and thus permanently rending the Union. Had England followed such a safely selfish policy there would probably have been no Chicago Exhibition, or at least a very much smaller one. The only reward vouchsafed her by the arrant partisan of the greatest people on earth is abuse for having let the "Alabama" escape to prey upon American shipping, and for which England voluntarily paid. Goodwill towards your rival can always be denied by him, but the advantage of position you have secured as against him is a self-evident and tangible thing, before which even he must be silent.—M. H.

(To be continued.)

### BRUSSELS SPROUTS.

THIS much-esteemed Brassica is one of the most useful vegetables to grow for autumn and winter use. It scarcely seems possible to have too many. Let the winter be what it may, we can always rely on getting a good return of sprouts, which are invariably highly appreciated, often to the extent of considerably lessening the supply by gathering before fully developed. This, I think, may be in some degree obviated by planting out a good breadth somewhat earlier than is usually practised. To do this of course it is necessary to devote a piece of ground solely to this crop, so that the stems of the plants may become strong and sturdy, a condition absolutely necessary for the production of a full crop of firm sprouts.

Rich firm soil is one of the greatest factors in bringing about this desirable state of affairs, so that when the land is in good heart no digging previous to planting is necessary; but if it is only moderately fertile a good dressing of manure should be given, and the ground dug deeply some time previous to planting; it is then an easy matter to tread firmly or roll the ground. Then by taking the precaution to give the plants plenty of room the growth made is strong, but at the same time sturdy and short-jointed.

The various strains of exhibition Sprouts are, I think, the best, and under proper cultivation the stems are packed from top to bottom with fine solid buttons. The earliest plants ought now to be ready for planting in their final quarters, and when planted out thus early I find 3 feet apart each way is not too much room to give them. If drills are drawn a couple of inches deep the work of planting is afterwards expeditiously performed, and should watering be required no difficulty is experienced in thoroughly moistening the soil around to reach all the roots. If the plants have been previously pricked out 4 inches apart, by the aid of a trowel they may easily be lifted with good balls of earth and planted where required, pressing the soil very firmly about the roots. When once established there is then but little labour needed save that of keeping the ground free of weeds till the first buttons are ready. It is, however, a good plan to draw a little soil up to the stems on each side, as it prevents them to a great extent from being damaged by wind.

Paragon is certainly a splendid variety, and should be largely grown where those of a dwarf habit of growth are preferred. The sprouts, which are produced in great abundance, are of extra fine flavour, and of a deeper green colour than many varieties. If the rows are arranged 2 feet asunder the plants may be set 18 inches apart in the rows. Northern Prize is another splendid variety, sturdy in habit of growth, requiring the same amount of space as preceding one. Other varieties might be enumerated, all of which have some feature to recommend them, but except for exhibition purposes there is no advantage gained in growing many sorts, and I think the three above named would be hard to beat. Our seed of the two last-named varieties being sown two or three weeks later than the exhibition strain, the plants are now ready for pricking into nursery beds; a good succession will thus be obtained, but I endeavour to have the principal plants early, as their value is then greatly enhanced.

Those who have at the present time ground lying idle will do well to plant as much of it as is practicable with this fine winter crop, and in some instances to plant between the rows of Potatoes

a little later on. In that case planting 18 inches asunder between alternate rows, and then lifting every other plant with a spade and planting to form intermediate rows (as soon as the Potatoes have been lifted) is the method I prefer. By so doing the Potato haulm may be kept comparatively clear of the young plants ; but it must be admitted that even this advantage is obtained at the expense of the Potato crop. All things considered I am convinced it is sound practice to keep Brussels Sprouts, as far as possible, clear of Potatoes or any other crop, excepting one which is likely to be cleared shortly after the plants are inserted. When a good breadth of early Spinach is grown, when it does not occupy a narrow border, an excellent position is obtained for Brussels Sprouts, as the Spinach will be ready for clearing away by the time they are growing freely.—H. D.

#### CATLEYA MOSSIÆ HOWARDIANA—WOOD WOOL FOR PACKING.

WILL you kindly give me your opinion as to the quality of the enclosed flowers of *C. Mossiæ Howardiana*? I believe it was named two years ago. I am afraid the flowers will not reach you in good condition as I can see signs of damping in the petals. I should also value your opinion as to the suitability of wood wool for packing flowers. I have sent a great number of Orchid blooms to Eastbourne and London this season, and am told they travelled perfectly. I am now sending to Malvern (eighteen hours' journey), which will be a severe test.—C. R. F.

[The flowers are of excellent quality, petals and sepals broad, smooth and clear, and the lip chastely coloured. They arrived quite fresh in the wood wool, of which we have not seen a softer, sweeter, or better sample. Some shavings we have received are too harsh for flowers, and so strong in the peculiar wood aroma as to impair the flavour of ripe fruit packed in the material.]

#### CULTURE OF CŒLOGYNE CRISTATA.

THERE are few more easily grown or profitable Orchids than *Cœlogyne cristata* and its varieties. The flowers are produced in drooping racemes during the first three months of the year, and being pure white, with the exception of a splash of golden yellow in the lip, are in great request for making bouquets, sprays, and wreaths, for which purposes the flowers are admirably adapted, as they wire well, are fragrant, and keep fresh in water for several days after being cut.

As a decorative plant this evergreen Orchid has few equals. Plants grown in pans from 4 to 6 inches in diameter are very useful for standing in small vases in rooms and for grouping or standing on edges of staging. The drooping spikes, consisting of from five to seven flowers, are very effective when contrasted with the groundwork of green shiny oblong pseudo-bulbs, from the base of which they spring, and the green arching leaves. Deep pans, about 12 inches in diameter at the top and 3 inches less in the bottom, well filled with pseudo-bulbs in full flower, show to great advantage stood on top of pedestals about 5 feet high in the boudoir and other rooms.

Potting should be done immediately the plants have finished flowering. Perfect drainage being essential to the well-being of this plant, from 2 to 4 inches deep of potsherds and small charcoal, according to the size of pan used, should be placed in the bottom of each, putting large pieces over the holes, and finishing off with small ones on the top, so as to secure a free passage for the water applied at the roots. A compost consisting of peat and sphagnum moss is generally given *Cœlogyne*s as a rooting medium, and they do very well in this ; but they do better in an admixture of equal parts good peat and loam, every particle of fine being shaken out, a little sphagnum moss and fine charcoal and potsherds added. In potting keep the mixture and pseudo-bulbs well above the rim of the pans, and make the compost firm.

The temperature of an ordinary plant stove will be congenial to the requirements of the plant, giving it a position near the roof glass and plenty of water at the roots during the summer and early autumn months. We grow our plants in the *Cattleya* house, which suits them admirably. Applications of weak liquid manure given at the roots twice a week during the period indicated will prove beneficial to the plants.

The largest plant I have seen of *Cœlogyne cristata* was at

Melchet Court, near Salisbury ; it measured 5 feet across, and bore over 500 large flowers.

Late-flowering plants which have not already been repotted should be seen to at once, shading them from sunshine during the heat of the day. *Cœlogyne cristata* was introduced into this country from Northern India in 1837.—H. W. WARD, *Longford Castle Gardens*.

#### ONCIDIUM PAPILIO.

THIS is the well-known Butterfly Orchid, a remarkable and free-flowering species. The flower spike rises from the base of the bulb, and bears a succession of single flowers, each one an almost exact representation of a butterfly. It produces flowers for years from the same stalk ; and if by accident it may be broken off at or near the top it begins to grow at once from the next joint below, and soon yields blossoms again.

This *Oncidium* is best grown on blocks, surfaced with fresh green sphagnum, in the spring, which should be kept growing all the summer, and in the winter the greater part of it ought to be removed, as too much moisture at the base of the bulbs is apt to cause them to decay. It should be grown in the hottest house, with abundance of sunlight and atmospheric moisture.

#### PHAIUS × AMABILIS.

THIS is a new and distinct hybrid, the result of a cross between *P. tuberosus* and *P. grandiflorus*. It was exhibited at the Drill Hall in February last by Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea, and a first-class certificate was awarded for it. The lip is comparatively short, brownish red, shaded with purple, this extending into the throat. The sepals and petals are bluish,

FIG. 82.—PHAIUS × AMABILIS.

veined with light brown. The plant is dwarf in habit, and is apparently a free bloomer. Fig. 82 represents the flower.

#### EPIDENDRUM BICORNUTUM.

Few Orchids have puzzled cultivators more than this beautiful *Epidendrum*. No one seems to have found a way to improve on imported plants of this species in the way that we can on some others. Possibly the best way to grow it is in pots or baskets filled with nothing but clear potsherds and charcoal and a little live moss when it is growing in summer, but whatever is used for potting the material should be of a very lasting character, as this Orchid cannot endure being disturbed at the roots.

If a newly imported plant once takes with a will to anything in the way of compost it will thrive and flower for a few years fairly well, but if disturbed it seldom takes well to its new home. This Orchid should be grown in the warm house and suspended near the glass to receive the full benefit of air and sun, and ought to be repeatedly syringed in the summer, also freely watered at the roots.—H. RICHARDS.

## WATERING, MULCHING, AND SHADING.

THE question of watering is always recurring. In a period of drought such as we are now experiencing an insufficient water supply makes itself felt to the worry of the responsible head, and often to the subordinate by the extra labour called for. I have lately heard from several gardeners about their troubles arising from a limited water supply, and also from a lady who, with a practically unlimited command of water, was afraid to allow its use in case it might prove detrimental, as she had been assured that artificial watering was always to be avoided. It is true that if watering can be avoided it is so much the better; but cases are constantly occurring when it is wise to apply water. There is no law other than the judgment of the cultivator as to how much or when water may be applied. The judgment may be that of experience, or of an experimental kind, and be therefore either good or bad; but we cannot define how or when to water so as to make it an easy subject to young cultivators.

One particular phase of watering that I shall touch upon is that whereby the application of water leads to further supplies being required. A most common example of this kind occurs in the treatment of fruit trees. I have seen it exemplified over and over again. Theoretically the practice is right, but when reduced to the exigencies of everyday routine it breaks down. This is something like what happens. Fruit trees are planted and a quantity of turf employed in the process, or it may be trees are only root-pruned and the same plan pursued. In any case the lumps of turf are as sure to become quickly dry in a short period of drought as the roots of the tree are certain to penetrate the turf. Watering of course follows, and in all probability it is continued as the liquid can be spared. In a season like this there is a breakdown. Now, the best loam without fibre is quite as good as turf, and as it dries no more quickly than well cultivated soil does there is an apparent benefit secured by employing loam. The proper pulverization of the soil forms indeed a means of combating drought, which is perhaps not generally recognised. It is quite common to see men when digging making the surface of the soil very smoothly, while lumps are left unbroken in the trench or furrow, and I am certain, from a long trial, that it pays, not only in the conservation of moisture, but in many other ways, to break every clod which is turned over. And, indeed, the main reason for trenching and digging is found in its being the only means of breaking the soil into small particles.

Another means of saving water consists in sowing deeply. It is not, perhaps, wise to cover the seeds deeply, but it is a good method to draw drills or even to make narrow trenches for seeds, though these drills and trenches need not be filled to the level. If water is required it is easily given by applying it along the depression left. Then, after becoming partial dry, let the depression be filled with soil. This plan is equally good for plants. I always carry it out in dry weather alike for vegetable crops such as Lettuces, Broccolis, and Cabbages, as well as for flowering plants, such as Asters, Verbenas, Ageratums, and indeed everything that is likely to suffer from drought before getting established. For plants such as Gladiolus growing on the level and already established, a drill is drawn out with a hoe close to the base of the plants. Along this drill the water is poured through a hose, and the soil thereafter pushed back. Of course when plants get large and the soil full of roots watering must consist in irrigating the land through and through, but at present few, if any, crops will require so much water.

I was pleased to see, some weeks back, a writer recommending common salt as a means of producing moisture. It may not be generally known that all salts employed as manures have a like property. So have phosphatic manures, none so much, perhaps as superphosphate of lime; but I notice that slag flour also exerts a wonderful influence on crops during a drought. In no instance is this principle so marked as in cases where any of these manures have been applied during dry weather as a surface dressing to any crop whether of vegetables or of flowers. The plants in a very short time show that they experience benefit, growing as they do with enhanced vigour and producing foliage of a stouter texture and darker colour.

To cereal crops I have this year applied a mulch of sifted compost. Tentatively I have employed the same material before, and the results justified the employment of more labour in extending what had proved a valuable cultural help. Such a covering, however slight, acts as a non-conductor. It has, moreover, the additional advantage of being distinctly beneficial as a manure. In top-dressing a series of borders I ran short of a supply this spring. The difference in the dressed and undressed sections was very marked indeed; no doubt in a way by conserving moisture, but certainly also by proving effective as a manure.

Much labour as well as water may be saved if some attention is paid as to the time of application. Even in dry weather the sun

does not shine every day nor all day long. Now I think it is not uncommon that hot sunny days are chosen in which to irrigate, and dull days are allowed to pass without being taken advantage of. A dull day is no doubt somewhat significant of rain, and therefore one hopes that watering may be avoided, but in reality these sunless days very seldom result in a downpour from the empty clouds; so that it is advantageous to make the most of them and water everything that needs it, or that is likely to suffer from continued drought. On sunny days the time to water is towards evening. Water is practically wasted when employed at any other time of day.

I shall conclude with a note on watering plants in pots. I have already pointed out the rapidity that trees planted in turf require to be rewatered. So with potted plants. If a light fibrous turf forms the staple compost the amount of water required to keep plants in vigorous health will be much greater than in cases where a loam with little or no fibre is employed. Hence, also, that the gardener who succeeds with his plants is the one who studies the kind of soil in which they are potted, and who applies water accordingly. Of course, a fibrous turf is a safer medium, because, notwithstanding its aptitude to dry quickly, there is little danger to the plant from an overdose of water, such as there is in the case of non-fibrous composts. A very good rule in all cases is that which allows just sufficient water to reach the drainage of the pot without any great quantity escaping. It is a fact that only a per-centage of young gardeners ever grasp the situation and become expert at watering, and I may say that I have never known one who did clearly understand it who has failed to grow all kinds of plants well.

But in addition to the application of water itself, I am sure that the distinct benefit of shading, however slightly, is greatly overlooked in the general cultural treatment of plants. Whenever the sun affects house-grown plants shade should be applied at once. A slight shading will do no harm whatever, whilst it certainly tends to keep the water-pot away, and at the same time obviates sudden and repeated dryness; is easily applied and as readily removed. I have used it for some time. It is prepared by mixing whiting with a little linseed oil and water. It can be made of any required thickness, though a very thin mixture does for most plants. If required tinted, a little colouring matter such as employed by painters for distemping walls is added, sufficient to give the desired tint. With the aid of a "stippling" brush a large surface is gone over expeditiously. I am certain that even such a slight shade as here recommended saves at least one-half in watering; while in other respects no harm, but most generally benefit, to the plants is the result.—B.

## PACKING AUSTRALIAN FRUIT.

IN pursuance of a request that I would get together a small jury of experts on fruit and fruit packing, the following gentlemen attended at the Imperial Institute on Friday, June 2nd:—Philip Crowley, Esq., F.R.H.S., F.L.S., F.Z.S., &c., Chairman of the Royal Horticultural Society's Fruit Committee; Dr. Robert Hogg, LL.D., F.R.H.S., F.L.S., &c., author of "The Fruit Manual" and a member of the R.H.S. Fruit Committee; George Monro, Esq., F.R.H.S., importer and salesman of fruit, Covent Garden Market; James Webber, Esq., F.R.H.S., importer and salesman of fruit, Covent Garden Market; Rev. William Wilks, M.A., F.R.H.S., Master of the Worshipful Company of Gardeners, Secretary of the Royal Horticultural Society, and a member of the Fruit Committee.

The question laid before them was—

- 1, To decide on the relative merits of the packing and general condition of samples of Apples and Pears from Melbourne.
- 2, To furnish useful hints (if any required) for the better packing of the fruit, and its arrival (if possible) in better condition in future in this country.
- 3, To offer suggestions as to the varieties sent.

On the first head they were unanimously of opinion that the samples sent from Tumuc Valley, Pakenham, were both the best packed and in the better condition.

On the second head they remarked that they were unable to commend the packing of either parcel. In the Neilson samples each fruit was enclosed in a paper bag, and the bags wedged in the cases with paper shavings. They considered bags in themselves undesirable, as preventing the escape of the necessary moisture sweating out of the fruit. The paper of these bags was also of a kind calculated to retain moisture. The Tumuc samples were loosely wrapped in squares of paper, which was considered the right method, and the paper was of a much better quality for the purpose. The Committee thought tissue paper the best.

The "padding with paper shavings" was considered unnecessary, and tending to retain moisture and prevent free circulation of cold air, and in the cool chamber in transit. The Committee recommend that the fruit be packed earlier—*i.e.*, that it should be in a less ripe state when packed; that each fruit should be folded in a square of tissue

paper, and that the fruits be then closely and firmly packed together in the cases, *no padding whatever being used* save just sufficient at the sides to prevent the fruits shaking out of place. The sides of the cases should be made of two parallel boards, with a *space left between them* to allow free exit of moisture and ingress of air during transit. The Committee attached the greatest importance to the words in italics. It should be mentioned that in both the Tumuc and Neilson parcels the Pears were all absolutely rotten, and arrived all in a mash; whereas some sent a week or two earlier only wrapped in tissue paper, with no padding, but with side ventilation to the cases, were still in almost perfect condition.

Under the third head, the varieties sent were London Pippin, Sturmer Pippin, Rome Beauty, Stone's Pippin, Jonathan, and Adams' Pearmain (it was said by a gentleman from Melbourne that Adams' Pearmain was called Dutch Mignonne in Australia, but there was no question with the Committee that the fruits were Adams' Pearmain, and had nothing to do with the true Dutch Mignonne). Of these varieties Sturmer had arrived in by far the best condition, leaving in fact little to be desired; and London Pippin in the worst, there being very few perfect or even passable fruits. The other varieties were all more or less woolly. Jonathan is a very attractive-looking Apple, and if it could be sent over in a less mealy condition would no doubt sell; but judging from the samples, Sturmer will prove by far the best market fruit. The same remark applies to Adams' Pearmain as to Jonathan.

With regard to the cases used the wood was considered sufficiently good for the purpose, but the ventilation at the sides, as in the Tumuc samples, was considered a *sine qua non*. It was incidentally remarked that much of the Tasmanian fruit lately sent has been spoiled by the very rough insides of the cases pressing unequally against the fruits. A specimen of a Tasmanian case was pointed out, the sides of which might be described as almost corrugated. Whether this be due to the very hard kind of wood used in Tasmania, or simply to the coarseness of the circular saw used in cutting the boards, the Committee were unable to say.

Signed on behalf of the Committee above named—W. WILKS, Sec., R.H.S.

#### ROSE SHOW FIXTURES IN 1893.

- June 14th (Wednesday).—Earl's Court\*.
- „ 15th (Thursday).—Newport.
- „ 20th (Tuesday).—Westminster (N.R.S.).
- „ 24th (Saturday).—Reigate.
- „ 26th (Monday).—Hitchin.
- „ 27th (Tuesday).—Maidstone and Sutton.
- „ 28th (Wednesday).—Clifton,\* Earl's Court, and Richmond (Surrey).
- „ 29th (Thursday).—Eltham and Windsor.
- July 1st (Saturday).—Crystal Palace (N.R.S.).
- „ 4th (Tuesday).—Bagshot, Canterbury, Diss, and Gloucester.
- „ 5th (Wednesday).—Croydon, Dursley, Ealing, Farnham, Hereford, and Lee\*.
- „ 6th (Thursday).—Bath, Farningham, Manchester, and Norwich.
- „ 11th (Tuesday).—Harleston and Wolverhampton.†
- „ 12th (Wednesday).—Earl's Court and Tunbridge Wells.
- „ 13th (Thursday).—Worksop (N.R.S.), and Woodbridge.
- „ 14th (Friday).—Helensburgh.
- „ 15th (Saturday).—New Brighton.
- „ 20th (Thursday).—Bedford and Trentham.
- „ 21st (Friday).—Ulverston.
- „ 25th (Tuesday).—Tibshelf.
- „ 27th (Thursday).—Halifax, and Southwell.
- „ 29th (Saturday).—Bedale.

\* Shows lasting two days.

† Show lasting three days.

During the present month a list of Rose Show fixtures will be issued each week, so that I shall be glad to have early notice of the dates of any shows not mentioned above, and also of any change of dates.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

#### ANNUAL DINNER OF THE NATIONAL ROSE SOCIETY.

We understand that the Very Rev. The Dean of Rochester, President of the Society, will take the chair at the annual dinner of the National Rose Society on the 20th inst. at the Horticultural Club Rooms, Hotel Windsor, Victoria Street, Westminster.

#### STRAY NOTES.

I HAVE turned to the Rose column of the Journal week after week in the hope of seeing an account from some well-known source as to how Roses are doing in this wonderful season, but, with the exception of the significant notice from Reigate, hitherto in vain. The season has been against writing, except when goaded by sparrows, for we have wanted all the daylight for work, and those who have been short-handed, or were in arrears, have had a busy time, for the position

being nearly a month earlier than usual in some things, it follows that we have had since March to do four months' work in three. In almost every other spring that I can remember there has been a time of greater or less duration, when it has been a common expression that "everything is at a standstill." Then poor laggards, like myself, have made up lost time, but this year things have always been getting forward from the sun and warmth, even if they could not grow much from want of rain. It has been "a run without a check"—capital for those who could keep pace with it, but a little seasonable check would not have been lamented by one at least who could hardly keep up with the things which wanted doing.

Between March 1st and May 21st we had only once (on May 2nd) sufficient rain to really lay the dust, and we still want it nearly as bad as ever. We tried long ago all the approved dodges which are usually successful in provoking rain, such as marking out the lawn tennis court afresh, leaving comfortable chairs and even valuable books out of doors at night; but in vain, and had begun to talk of the advisability as a last resource of sending a deputation over to hang Professor Falb, who foretold the drought, when luckily Jean Ducher came to the rescue by producing two fine buds in just the condition to be spoiled by a shower. We ceased watering, in the full conviction that if those buds did not tempt a prowling thunder shower nothing would, and that in that case I should at least see a good Jean Ducher in the open, which I have not done for many years. The bait took as I thought it would, but alas! though it takes a very little rain to spoil a Jean Ducher, it would now take a great deal to quench our thirst; and we are, though a little refreshed, by no means satisfied.

I expect we have all had some difficulties to contend with. I did not know what to do with my Rose beds, which were so hard they could not be hoed without being watered, and could not be watered without being hoed. I had to break them first with a pick. Then, to my shame, I was behindhand in planting out my Briar cutting stocks, and had to do this in April when the earth was like iron and the heavens as brass, and the plants themselves were green and growing. But there is a great deal in careful planting, and nearly all look better than I anticipated. I heard of one gallant rosarian who hired the town fire engine and twelve men for a week to keep his stocks alive; and of another who left off watering in despair. The Dutch hoe has once more proved an efficient substitute for the watering pot (though it is better still as an aid) in many places; and, in general, stocks and all moved plants have been those that have suffered the most and required the greater attention. I hope that other Briar cuttings inserted last year do not look as bad as mine.

As to caterpillars and grubs, I did not mean to suggest, when I wrote at pruning time, that there would be none, but that there would probably be fewer than usual, and this is the case here in a marked degree. I fully expect that Mr. Mawley, whose statistics on these and other rosarian matters are so valuable, will confirm my opinion. A large majority of the buds look well formed and promising. The wood growth is naturally not great, but a harvest with good ears but short straw is not uncommon, and I hope this may be the case with Roses.

I suppose Reigate has expressed the general estimate of the season by making their date a fortnight earlier; but "three weeks earlier than usual" would, I expect, be the prognostication of some localities. A great deal depends upon June, and I myself do not expect to be much more than a fortnight before the usual time. My standard Teas, especially those which were buried, do not look as if they would be forwarder than usual. I think the burying answered very well with all those which had to be pruned, but the Maréchal Niels do not seem to have approved of it. They are growing well and strongly, but show few signs of flowering even from the long wood of last year.

It certainly seems as if some warmly debated questions as to the date of the National Show will be answered this year. We ought at least to be able to see what is to be seen of northern growers, and *somebody* at least will have the gratification of saying, "I told you so."—W. R. RAILLEM.

#### GLOXINIAS AT SHROVER HALL.

THE finest Gloxinias I have ever seen are now growing in Sir William Pink's garden, a few miles from Portsmouth. Many of the plants measure 2 feet in diameter and carry fifty blooms, some measuring  $4\frac{1}{2}$  inches in diameter. The bulk were of the upright section, a few semi-drooping. The foliage was luxuriant, one leaf measured being 11 inches in length and 8 inches in diameter. As we do not find Gloxinias so fine in every garden, a note on Mr. Hunt's method of culture may not be out of place.

The seed (Sutton's) was sown in February last year, consequently the plants were sixteen months old at the time of flowering the second season. Last year they bloomed in July. The seed was sown in heat in the usual way, the plants pricked off and potted when ready. The corms were wintered in the Mushroom house in the pots in which the plants flowered. In February of the present year they were placed in a newly started vinery to make their first growth, the moisture required for the Vines just suiting the Gloxinias. Mr. Hunt does not approve of

shaking the combs out of the soil in which the plants were grown. He considers many roots are broken, or so damaged by that practice, that the most fibrous are of little use to the plants. By shifting into larger pots without removing the old soil the roots are preserved intact. A plant flowering last season in a 48-size pot will this year be shifted into a 7-inch one. The compost employed consists of two parts loam, one of decayed leaves, and one of peat, a quart of bonemeal and a handful of soot being added to every bushel of compost. Some of the largest plants were still in the pots in which they flowered last year. Their appearance demonstrates that Mr. Hunt has made no mistake in the method of culture he has adopted with such marked success.—E. MOLYNEUX.

**EVENTS OF THE WEEK.**—As previously announced, a Rose Show will be held at the Gardening and Forestry Exhibition, Earl's Court, on June 14th and 15th. On the 14th inst. also the grand Yorkshire Gala will open at York, continuing the two following days.

— **THE WEATHER IN LONDON.**—Bright and sunny weather has for the most part again prevailed during the past week. Slight showers fell on Saturday evening, and on Tuesday night there was a refreshing rain. As we are preparing for press it is bright and warm.

— **THE ROYAL HORTICULTURAL SOCIETY** intends holding a Show at Chiswick Gardens on July 11th. Prizes to the amount of nearly £150 are offered, besides two silver cups. There will also be a great Show at the Agricultural Hall on August 29th, 30th, 31st, and September 1st, at which over £460 is offered in prizes, as well as medals and cups. Schedules of either Show can be obtained from the Secretary, R.H.S. Offices, 117, Victoria Street, S.W.

— **NATIONAL CARNATION SOCIETY (SOUTHERN SECTION).**—At a Committee meeting held at the Hotel Windsor on June 3rd it was unanimously agreed that, owing to the exceptionally early season, the date of the Exhibition which was to have been held in the Drill Hall, James Street, Westminster, on July 25th, under the auspices of the Royal Horticultural Society, should be altered to July 11th, and that the Exhibition be held in the gardens of the Royal Horticultural Society at Chiswick on that date.—JAS. DOUGLAS, *Hon. Sec.*

— **NATIONAL AMATEUR GARDENERS' ASSOCIATION.**—At the monthly meeting of this Association, held at the Memorial Hall, Farringdon Street, E.C., on Tuesday, June 6th, under the presidency of Mr. T. W. Sanders, an admirable lecture on "Fertilisation" was given by Mr. W. Cuthbertson. There was a very large audience, who appreciated the lecturer's remarks. Mr. Cuthbertson dealt with his subject in an able manner, and by the aid of well-executed diagrams expressed himself clearly on many technicalities. A hearty vote of thanks was accorded the lecturer. Messrs. Dobbie & Co., Rothesay, sent a large collection of Violas and Pansies, and Mr. H. J. Jones, Lewisham, some charming Pelargoniums.

— **NATIONAL CHRYSANTHEMUM SOCIETY.**—The annual outing of the members will take place on Monday, July 17th, Lord Carrington having given his permission for a visit being made to the grounds of Wycombe Abbey, High Wycombe. Among the arrangements for the day will be a match of cricket with the members of the Aylesbury Floral and Horticultural Society, who will be accompanied by a number of friends from that town. Arrangements will also be made for visiting Hughenden Manor, and for inspecting one of the large chair-making establishments in the town and other places of local interest.

— **SUTTON'S RINGLEADER POTATO.**—Mr. E. Molyneux, Swanmore Gardens, writes:—To further test this early Potato, of which I had previously formed a high opinion, on March 6th I planted several rows on a south border somewhat exposed to easterly winds. At the same time I planted an equal number of Sharpe's Victor. The tubers of both sorts were well sprouted. The former was ready to dig May 20th, and the latter one week later. In point of size and cooking qualities Ringleader in my opinion was in advance of the Victor. I may say that the soil here is not of the best kind for the growth of early Potatoes, being rather too heavy. Last year our first digging of Ringleader from the same site was June 3rd, planted April 4th.

— **GARDENING APPOINTMENT.**—Mr. Thos. Lowton, gardener for the past four years to the late Mrs. Carter, of Ospringe House, Faversham, has been re-engaged by the present owner, A. J. Gillott, Esq.

— **A GOLD MEDALLIST.**—The gold medal of the Linnean Society has this year been awarded to Professor Daniel Oliver of Kew, to whom it was presented at the anniversary meeting of the Society held at Burlington House on the 24th ult.

— **STRAWBERRIES IN LONDON.**—English Strawberries from early localities are now selling freely in the streets of London at about 4d. per lb. As a rule the fruit is much below the average in size, doubtless owing to the prolonged drought.

— **THE INNER TEMPLE GARDENS.**—It is stated that, by permission of the Treasurer and Benchers, the Inner Temple Gardens will be opened to the public from to-day (Thursday) until the end of August, between the hours of six and nine o'clock in the evening.

— **FROST IN JUNE.**—A Wood Green correspondent writes:—"It may interest your readers to know that in this district a frost occurred early in the morning of June 1st. Vegetable Marrows, Scarlet Runner Beans, and Potatoes were much injured in some allotments in the neighbourhood."

— **EARLY CHERRIES.**—We are informed that Mr. Peter Cornwall of Bredgar, Kent, commenced gathering Cherries on the 26th ult. The variety was Adams' Crown, which usually ripens early in July. It would be interesting to hear of other instances of "record breaking" as regards the earliness of fruit-picking.

— **PEA MAY QUEEN.**—On March 6th I sowed seed of this new wrinkled Marrowfat Pea along with English Wonder on a south border, and gathered the first pods from the former May 22nd, and from the latter on the 27th. May Queen is, without doubt, an excellent early variety, growing 2½ feet high, and bears an abundant crop of well-flavoured peas. It is much in advance of William I., or any of that type, in point of flavour.—E. MOLYNEUX.

— **PANSY BELLA DUNCAN.**—Mr. Michael Cuthbertson, Public Park Nursery, Rothesay, sends us blooms of his new Fancy Pansy Bella Duncan. It is a beautiful variety, the flowers being exceptionally large and of great substance. The blooms are characterised by large, rich purple blotches, the side and lower petals being evenly edged with white. The top petal is also similarly blotched with a deeper white margin. It is said to be very dwarf in habit, free flowering and robust, well suited for exhibition or bedding.

— **POLLINATION OF TOMATOES.**—A "Constant Reader," on page 416, gives the result of a microscopic examination of the stigmas of Tomato flowers after the ordinary and American methods of distributing the pollen was resorted to, and finds no appreciable difference in favour of either plan. He will confer a great favour by repeating the experiment next autumn or early in the winter, this being when a good set is less easily effected, and when the American method I described on page 350 should prove its superiority over merely tapping the stems.—W. IGGULDEN.

— **PACKING SCIONS.**—The question (page 393) relating to the packing of scions prompts me to say that I have had small stools of Chrysanthemums sent to me from New Zealand, arriving in good condition. As the Editor remarks, oiled silk is excellent material for the outer covering. In my case the roots were wrapped in damp moss and enclosed tightly in oiled silk. After travelling all that distance I was enabled to get the plants to grow without any trouble whatever. If this method is successful with roots of Chrysanthemums it surely would be with scions of fruit trees.—E. MOLYNEUX.

— **EARLY GEM CARROT.**—Captain F. Daubeney writes:—Mr. Dunkin mentions this variety on page 435. My own experience is that it is the earlier and the better in comparison with Early Nantes. This year I sowed Early Gem in a frame on February 8th. Owing to the season being so warm the lights were removed on March 8th, and never afterwards put on, night or day. All the crop has been pulled, and an excellent one in every respect. I grew Early Nantes by the side of Early Gem in frames in 1891. Since then I have grown only Early Gem for first supply of Carrots, and my experience has told me it is the best, as James' Intermediate is for main crop. Another of Sutton's early vegetables deserves mentioning, it is Cauliflower Magnum Bonum. Sown this year on February 1st, I commenced cutting on June 2nd, and this is in some respects a bad season for Cauliflowers.

— **SUNFLOWERS IN HOSPITALS.**—A correspondent writes to a Cornwall paper:—"If there were large numbers of Sunflowers in pots in all hospitals, they would do great good, absorb the impure air, and give out what would be beneficial, and it would be a great improvement if plants instead of cut blooms were sent to them. If the water is often changed the flowers will last fresh much longer."

— **DESTROYING CRICKETS.**—I successfully capture crickets by placing jam jars half filled with beer near where I know the pests abound. I simply sink the jars to the rim, and examine and take out the dead crickets every morning. Woodlice, too, are caught very easily in this way. It is no uncommon occurrence for a cluster of Grapes to form at the extreme point of a shoot; I always take them off.—J. HINTON.

— **EARLY POTATOES IN SCOTLAND.**—A northern correspondent, writing under date, May 30th, says:—"Bute Potatoes will be in the market about three weeks earlier this year than usual. Those grown on the farm of Langalchorad, Kingarth (Mr. Hugh Duncan's), are generally first, and yesterday (29th ult.) several parcels, the first lifted in the island this year, were brought into Rothesay. They are quite ready for use, and are remarkable for size and appearance at such an early period of the season."

— **THE TOTAL RAINFALL AT ABBOTS LEIGH, HAYWARDS HEATH, SUSSEX,** for May was 0.67 inch, 1.28 inch below the average. The heaviest fall was 0.30 inch, on the 17th. Rain fell on seven days. The maximum temperature was 80°, on the 15th; the minimum 37°, on the 1st and 31st. Mean maximum, 68.4°; mean minimum, 45.2°. Mean temperature, 56.8°, about the average. The rain here has not been sufficient to do much real good, followed, as it has been, with bright sunshine and drying northerly winds.—R. I.

— **ECHEVERIA PEACOCKI.**—This succulent, one of the most striking for carpet bedding, is very largely employed at Hampton Court. It seems to be a very difficult variety to winter, as it is so susceptible to damp. For that reason it is found best to keep all the plants in small pots singly, keeping the soil somewhat dry, and standing them on upper shelves in the greenhouses. Once damp seizes upon the plants it is difficult to save them. It does not seem possible to obtain seed, but propagation is carried on by pulling off the lower and partially decayed leaves from the older plants, and laying them upon sand, where being gently damped and shaded they presently make root and growth. When the plants reach some four to five years old they are beheaded, the crowns rooted as cuttings, and if the stems break into growth the side shoots are also utilised as cuttings. It is only by the exercise of constant care and attention in the direction of propagation that a good stock is maintained.—A. D.

— **BIRMINGHAM AMATEUR GARDENERS' ASSOCIATION.**—A large party of members and friends made up an excursion party on the 3rd inst. to Stoneleigh Abbey and Kenilworth, first visiting Mr. Henry Whateley's extensive market-growing establishment. The party then visited Stoneleigh Abbey Gardens, under the guidance of Mr. Biddard, the crops of Grapes, including two houses of Muscats; a large quantity of forced Strawberries, the old variety Lucas especially fine and high flavoured; and the extent and well-kept and cropped gardens being greatly admired. Hardy fruits are extensively cultivated here, and there are many well managed wall trees. There are fair crops, but the caterpillar is a trouble in the kitchen gardens, and in the woods a large number of trees and the Hazel bushes are almost stripped of foliage.

— **CUCUMBERS, TOMATOES, AND MUSHROOMS.**—Kenilworth has a great reputation for Strawberries, many tons being sent away to the different markets, and it is also gaining a celebrity for other market crops. Mr. Henry Whateley, Spring Gardens, had for a few years twenty houses in two blocks of ten each, each house 120 feet long, in use for Tomatoes, Cucumbers and Mushrooms, and a twelvemonth since he completed another block of ten houses, each 210 feet long, and these are all, with one exception, cropped with Cucumbers and Tomatoes, the latter a selected Old Red chiefly. There are grand crops in the various houses, an average of two tons being sent away weekly. The one house alluded to was planted with young Vines in May, 1892, and are making great headway, being very strong and many of them bearing fruit. Mushroom beds out of doors as laid down in Mr. Wright's book on Mushroom culture, are plentiful and cropping heavily, with only some straw litter thrown over them, showing how easy a thing outdoor culture is under proper conditions.—W. D.

— **INSECTS AND FRUIT TREES.**—Red spider has appeared, but I overcame it with a timely application of black soap and hellebore in two applications, but fear its effect was lost on caterpillars, which are a plague. The sparrows have, however, taken them in great numbers. The black aphid has invaded many bushes. Spraying with insecticides, and nipping the points off the growths are the best methods to prevent a loss of crop.—W. T.

— **POPULAR BEDDING.**—In spite of the efforts made to minimise carpet bedding yet does it seem to be as popular as ever with the masses, who are loud in their expressions of admiration for the beauty of many of the designs and the skill with which they are worked out. There seem to be three forms of bedding just now competing for popularity, but perhaps all the more pleasing when seen in juxtaposition for contrast—carpet beds, mixed beds, where a score of diverse plants are somewhat close together, forming a pleasing irregular mass, and Begonia beds, which are filled thinly, each plant standing well apart, the soil being surfaced with some spreading carpet plants. It is well that we have these styles and each one has admirers. Few, however, seem to be more attractive as well as simple than are the Begonia beds.—A. D.

— **A VARIEGATED OAK SPORT.**—When I was recently in the Royal Gardens, Kew, I observed high up on one of the branches of a large Turkey Oak a remarkable outbreak of small shoots from one place only, all clothed with leafage of a pale creamy tint. As the growth for so abnormal a form of leafage is fairly robust it seems as if the sport could be worked on to young stems, and in that way be perpetuated. I do not know whether any such experiment has been tried at Kew, but it seems to be worth attempting. It is not that creamy foliage of hardy trees is specially beautiful or effective, but at least the perpetuation of a sport of that description might have some value from a purely scientific aspect. How interesting it would be were a post-mortem examination of the branch possible, and the cause of this abnormal absence of green colouration in the leafage fully demonstrated.—VISITOR.

— **THE LATE MR. SAMUEL BARLOW.**—Not mentioned in your notes respecting this excellent and deeply regretted florist, most certainly not intentionally, was his famous act in growing the finest dish of Apples ever seen, and which formed so striking an object in the Guildhall Fruit Show and afterwards in the fruit present made to the Queen from the Exhibition by the Fruiterers' Company. Mr. Barlow's superb Peasgood's Nonesuch excited the wonder and admiration of all who saw them. Yet were they but illustrative of all horticulturally that he did, for he would have all things done well, and shown well. It was not very often we saw him south; he occasionally attended the Shows of the Auricula Society, and those not lately. When he did come he rarely failed to bring something good with him. It was far less his ambition to take prizes than to have the best things, because he believed in quality, and that of the finest cultivation could produce.—A.

— **SUMMER BEVERAGES.**—Mr. A. W. Duncan, F.C.S., writes as follows in "The Vegetarian Messenger":—"Fruit flavourings, such as Pear, Apple, Pine Apple, Strawberry, and Raspberry, have rarely had their origin in fruits. They are preparations of various ethers and alcohols. When used in very small quantities, so as to give only a slight flavour, the best of them are probably of no sensible injury; but aerated drinks, and even sweets, often contain a very objectionable amount. Some of the cheap temperance drinks sold at wayside houses are injurious; they sometimes produce a fulness and throbbing in the head. Fruit cordials consist nearly always of solutions of sugar, with artificial fruit essence, and a little citric or other acid. The best drink for quenching thirst, other than pure water, is Lime or Lemon juice. Simple aerated waters, containing nothing but a little sugar, citric acid, and a small quantity of Ginger or Lemon essence, are not to be condemned if they are of good manufacture. We are compelled to pay a high price for these at most hotels, and ought to receive a pure article; but it is a very common thing for hotel keepers to pay a very low price to the manufacturers. Many manufacturers, for the sake of a slight saving in cost, substitute hydrochloric acid for some of the proper fruit acid (citric or tartaric) in their drinks, and they give as a reason for the deterioration the competition and cutting of prices. Some of the so-called 'unfermented Grape juices,' as sold in bottles, are not as innocent as they profess to be. The temperance drinks, as they are generally termed—the fruit cordials and non-intoxicating beers—are but little used by vegetarians and teetotalers."

— GARDENING AND LOCAL INDUSTRIES IN IRELAND.—Dr. Boeddicker sends us the schedule of a Show to be held at Parsonstown on August 17th, which indicates that considerable interest is taken in the furtherance of gardening, bee-keeping, and other useful occupations in the district. The Earl of Rosse is President of the Parsonstown Society, and Dr. Boeddicker one of the Honorary Secretaries.

— KINGSTON AND DISTRICT GARDENERS' ASSOCIATION.—This young Society continues to meet monthly during the summer, as it was feared that entire cessation would be harmful. On Tuesday last Mr. Tibble, a member, read an interesting paper on "The Tomato," descriptive of his method of culture. The free use of the syringe by him elicited some surprise amongst the members, and this point, with several others, was freely discussed by Messrs. Hawkes (Chairman), Cushon, Henbest, Peed, Martin, Dean, and others. With respect to flavour in varieties, much difference of opinion cropping up, it was agreed that somewhere towards the autumn an opportunity to taste the numerous sorts grown by the members should be offered, as likely to create much interest.

— VARIEGATED PELARGONIUMS.—It was recently remarked that the various golden tricolor Pelargoniums are once more coming into favour for bedding purposes. That is equally true of the golden and bronze Zonal forms, the very best of which seems still to be Marshal McMahon; no doubt the finest zoned yellow leaf variety ever raised. Next that comes Black Douglas. It will not be a matter for surprise to find raisers once more devoting their attention to these forms. Then there is always a demand for the very effective old Crystal Palace Gem, the best of the golden zoneless section. No variety of its colour has ever excelled it, perhaps never will. As to the silver variegated forms, Flower of Spring continues to be the best perhaps, but should not be allowed to flower if the foliage be especially needed to produce a pleasing effect.—D.

— AN EXCELLENT FORCING STRAWBERRY.—Lucas, an old and comparatively little known variety as adapted for forcing, was recommended to Mr. Beddard, head gardener at Stoneleigh Abbey, by another gardener as a first-class forcer, and he has grown a good number this season. The fruit is of large size compared with forced kinds generally, firm, not at all subject to mildew, of good colour, and of a sweet rich flavour. Compared with other sorts under the same treatment the flavour is very superior to that of Sir Joseph Paxton, which at Stoneleigh is subject to mildew, La Gros Sucrée, Waterloo, and others forced here. It stands so high in Mr. Beddard's estimation as to be used largely another season, and out of doors it is a very good cropper. Large consignments of fruit are sent from Stoneleigh Abbey to Lord Leigh's London house, so that a Strawberry with the good travelling qualities of Lucas is a boon, and its most pleasant flavour when forced considerably enhances its merits. Out of doors the Strawberry crop is good. Noble is the earliest, and Waterloo and Eleanor will be the latest. The River Avon has a broad stretch at the foot of the sloping pleasure grounds close to the kitchen gardens.—W. D.

— PROTECTION OF PLANTS.—It is known that certain plant stuffs (alkaloids, tannin, oxalic acid, &c.) protect plants from attack by animals. This function, in the case of oxalic acid, says *Nature*, has been recently studied by Herr Giessler (*Jenaische Zeits*), taking species of *Rumex*, *Oxalis*, and *Begonia*. The acid mostly occurs in the epidermis and peripheral tissues of the vegetative organs; parts underground have little or none. The leaves show most, but the acid may be found in the stem and the leaf and flower stalks. Curiously, it does not, like other protective matters, appear in young organs. The older and more sappy the tissues the more oxalic acid do they contain. Snails, which avoided those plants in the natural state, ate them when the oxalic acid had been precipitated. The substitution of various means of protection for one another was elucidated by Stahl; plants not protected mechanically have chemical protection and *vice versa*. In the plants studied by Herr Giessler mechanical protection is deficient. Further, in organs that have little or no oxalic acid is found tannin. These two "vicariate" with each other also in different species of a genus. In many tissues both occur together. The protective function of a secretion, lastly, does not exclude other functions. Thus, regarding the epidermis as a water reservoir, the osmotically very active organic acids doubtless play an important part in the filling of the cells with water. The occurrence of *Begonia* and *Oxalis* species in very dry places, as also the deficiency in means of protection against transpiration, more pronounced the higher the quantity of acid, put this function of oxalic acid in a still clearer light.

— APPLICATION OF ARTIFICIAL MANURES.—Messrs. H. and E. Albert, 17, Gracechurch Street, E.C., send us Professor Paul Wagner's pamphlet on the above subject. It contains much valuable information, and is illustrated by striking photographic illustrations. The Professor bears effective testimony to Albert's concentrated horticultural manure, now being advertised, as he may well do, seeing that it is guaranteed to contain 14 to 16 per cent. of phosphoric acid, 20 per cent. potash, and 17 per cent. nitrogen, which are undoubtedly the most potent elements in the food of plants and crops.

— WEATHER AT SWANMORE.—Writing from Swanmore Gardens, Mr. E. Molyneux observes:—"Since my last note on the weather appeared in the *Journal* (May 11th), we have had agreeable rains, a total of 0.73 inch falling in five days, beginning May 16th. Since that we have experienced fifteen consecutive dry days, the spell being broken by a slight shower (0.12 inch) to-day (5th), making a total for the year of 6.97 inches—a small quantity. I never saw the soil in so dry a state as at the present time; not a particle of moisture is to be found for at least 2 feet deep. In the valleys around here a sharp frost was experienced on the morning of June 1st. The Potatoes suffered considerably in nearly all low-lying gardens. Here the thermometer did not descend below 40°."

— THE WEATHER LAST MONTH.—May was very dry, with the exception of six days (15th to 20th), the total rainfall being 1.67 inch below the average for the month. It was not so hot as April. The wind was in a northerly direction twenty-one days; we had thunder on four days, but no heavy storms. Barometer: highest, 30.50 at 9 A.M. on 6th; lowest, 29.52 at 10.30 P.M. on 17th. Total rainfall 0.76 inch, which fell on ten days, the greatest daily fall being 0.46 inch on 17th. Temperature: highest in shade, 75° on 4th; lowest, 33° on 7th; lowest on grass, 23° on 7th. Mean daily maximum, 66.38°; mean daily minimum, 44.13°; mean temperature of the month, 55.25°; mean grass minimum, 37.96°. The garden spring ran 20 gallons per minute on 31st. Grass and corn are waiting rain very much, but Wheat looks well in many places where the land is in good order. We hoped the drought was at an end with the shower on the 17th; but it has since been as bad as before.—W. H. DIVERS, *The Gardens, Ketton Hall, Stamford*.

— THE WEATHER IN HERTFORDSHIRE.—Mr. E. Wallis, The Gardens, Hamels Park, Buntingford, Herts, writes:—"The weather during the past month has been exceptionally bright; not one full dull day. Some sharp frosts have been registered, but fortunately they have not done much damage, owing to the very dry atmosphere. Rain fell on seven days during the month. Maximum in any twenty-four hours was 0.55, on the 29th; minimum in any twenty-four hours was 0.02, on the 19th. Total during the month, 1.21, against 1.37 of 1892. In spite of the dry spring, the rainfall has been higher this spring than that of 1892. By the end of May last year I had registered 6.15 of rainfall; by end of May, 1893, I have registered 6.24. Red spider and caterpillar threatened to become very prevalent, but by using London purple the caterpillar was easily destroyed, and employing petroleum and softsoap red spider has been held in check."

— STRAWBERRY TRAINS IN AMERICA.—In this country, during the fruit season, it is no uncommon thing to see truckloads of hampers of Strawberries, but we do not appear to have such facilities for transit as they have "on the other side." It is stated that it is possible, "by means of rapid transit, to extend the fruit season of any particular centre to four or six times the normal length. Strawberries first make their appearance in large quantities at Chicago in January, brought in fast express trains from Florida. Then as the Florida beds become exhausted, Louisiana fruit comes into the market, bringing the year up to the first part of March; Alabama next, a little nearer north, follows; while Mississippi brings the supply which carries the people over to the opening of the Illinois Strawberry season. Towards the end of May over twenty carloads of Strawberries, or 420,000 quarts, arrived in Chicago every day, and now the supply is doubled. In the height of the season, exclusive Strawberry trains are run from Cairo in the southern part of the State, stopping only to pick up loaded cars. Often these 'specials' will consist of thirty railway carriages, each carriage loaded with 450 crates of Strawberries, the entire train bringing into Chicago when fully loaded, 324,000 quarts. The scene presented at the Union Railway Station on the arrival of a 'Strawberry express' is unique and very interesting. Two hundred and fifty express waggons are drawn up on both sides of the railway line, while five minutes after the train has come to a standstill a small army of 800 or 1000 men are busy unloading the fruit, only gathered a few hours before."

— SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS. — Mean temperature of month, 54°. Maximum on the 4th, 74.6°; minimum on the 6th, 29°. Maximum in the sun on the 14th, 127.9°; minimum on the grass on the 7th, 22°. Mean temperature of air at 9 A.M., 57°. Mean temperature of soil 1 foot deep, 54.2°. Number of nights below 32°, in shade two, on grass seven. Total duration of sunshine 182 hours, or 37 per cent. of possible duration. We had two sunless days. Total rainfall 1.56 inch, rain fell on ten days. Average velocity of wind 7.2 miles per hour, did not exceed 400 miles on any day, and fell short of 100 miles on four days. Approximate averages for May:—Mean temperature, 51.1°; sunshine, 175 hours; rainfall, 2.11 inches. Another warm and fine month. The drought which set in in the middle of March lasted up to the 17th, when only 0.60 of rain had fallen in sixty-one days. The mean temperature is higher than in recent years except 1889.—JOSEPH MALLENDER.

— CABBAGE COMPETITION.—Notwithstanding the severe winter and prolonged drought Messrs. Stuart & Mein's annual competition for early Cabbages, which took place on the 27th ult., proved as great a success as in former years. The £5 premium which they offer for the heaviest specimen of Mein's No. 1 Cabbage is open to the United Kingdom, the only condition being that the seed should be procured direct from the firm. Mr. J. H. Luxmore, Beeralston, Devonshire, proved to be the winner with a Cabbage weighing 12 lbs 12 ozs.; Mr. C. Jacobs, Niton, Isle of Wight, being a close second with one 12 lbs. 8 ozs. The returns of the weights from the various counties were extremely interesting, as showing with what varied success the early Cabbage crop has been cultivated throughout the country. Taking the heaviest single specimen grown in each county the result was as follows:—Devonshire (Beeralston), 12 lbs. 12 ozs.; Hampshire (Niton), 12 lbs. 8 ozs.; Pembrokeshire (Merlin's Bridge), 10 lbs. 2 ozs.; Rutlandshire (Uppingham), 10 lbs.; Glamorganshire (Aberavon), 9 lbs. 11 ozs.; Cornwall (Hayle), 9 lbs. 5 ozs.; Essex (Billericay), 9 lbs.; Sussex, 8 lbs. 12 ozs.; Ayrshire, Flintshire, and Monmouthshire, 8 lbs. each; Lincolnshire, 7 lbs. 11 ozs.; Somersetshire and County Roscommon, 7 lbs. 8 ozs. each; Kent, 7 lbs. 4½ ozs.; County Sligo, 7 lbs. 4 ozs.; Buckinghamshire, Berkshire, Merionethshire, and Staffordshire, 7 lbs. each; Brecknockshire and Cambridgeshire, 6 lbs. 8 ozs. each; Oxfordshire, 6 lbs. 4 ozs.; Derbyshire, 6 lbs.; Norfolkshire and County Armagh, 5 lbs. 15 ozs. each; Isle of Man, 5 lbs. 12 ozs.; Dorsetshire, 5 lbs.; County Durham, Surrey, and Bedfordshire, 4 lbs. 15 ozs. each; Lancashire, 4 lbs. 14 ozs.; Nottinghamshire, 4 lbs. 12 ozs.; Linlithgowshire, 3 lbs. 15½ ozs.; the remainder being from 2 to 3 lbs. each. The two heaviest specimens from one county came from Hampshire, 12 lbs. 8 ozs. and 9 lbs. 6 ozs.; Devonshire being second with 12 lbs. 12 ozs. and 8 lbs. 15 ozs.—(*Kelso Chronicle*.) ✓

## ROYAL HORTICULTURAL SOCIETY.

JUNE 6TH.

THERE was a fair display of flowers at the Drill Hall on Tuesday last. Orchids were not so extensively staged as usual, neither were greenhouse and stove plants, but hardy flowers formed the bulk of the exhibits; Melons, Strawberries and Peas were also well represented. In conjunction with this meeting the first Exhibition of the London Pansy and Violet Society was held, and a report of this appears elsewhere.

FRUIT COMMITTEE.—Present: P. Crowley, Esq. (in the chair), with Rev. W. Wilks, and Messrs. John Lee, T. F. Rivers, Harrison Weir, G. W. Cummins, J. Cheal, G. Taber, T. J. Saltmarsh, W. Warren, A. Dean, H. Balderson, F. Q. Lane, C. Ross, and J. Wright.

A good portion of the time of the Committee was occupied in tasting Melons, ten new varieties having been sent in the hope of their obtaining some mark of recognition, but only one was honoured with an award of merit, though two or three others might have found favour if they had been in their best condition. Very great care was taken in the examination of the fruits, each member of the Committee recording his judgment individually. The result of this was an unanimity of opinion that decidedly the best Melon was sent by Mr. Owen Thomas from the Royal Gardens, Frogmore, and hence the award above mentioned. It was the result of a cross between High Cross Hybrid and an unnamed seedling. Fruit of good medium size with a yellow rind, slightly netted; flesh greenish white, thick, melting, and remarkably juicy, sweet and refreshing. This new variety was named Frogmore Seedling.

Among other varieties of promise, and which the Committee desired to see again in better condition, were a handsome and well netted green flesh from Mr. J. Hunt, The Gardens, Ashstead Park; a large, closely netted pale green fleshed fruit from Mr. C. Ross, gardener to Colonel Archer Houbton, Welford Park, Newbury; Reigate Ruby, a distinct deep scarlet flesh Melon, rich but over-ripe, from Mr. C. Ritchings, gardener to Dr. Frankland, Redhill; and a scarlet flesh from Mr. A. Bishop, gardener to R. Burrell, Esq., Westley Hall, Bury St. Edmunds,

rich, but with a peculiar flavour that may have been the result of over-ripeness. Melons will not always ripen just when they are wanted, and Mr. Ritchings' seedling appears to ripen, very awkwardly for him, between the meetings, but may be expected to come right some day. As other varieties were passed without special comment it is scarcely necessary to particularise them. Quality is the first consideration in Melons, but they should also be good in appearance as well. Some were handsome but not good, others were neither good nor good-looking, and it is noticeable that far more fruits are placed on the table in an over-ripe than unripe condition. Mr. W. J. Myatt, Hextable, Swanley, sent six beautiful fruits of the Conqueror, such as he grows for market, no doubt selling readily, and a vote of thanks was accorded.

Mr. J. Collis, Rolls Lane, Acton, sent a dish of his new Strawberry May Queen, fruits of which were ripe in the open ground on May 20th. while those of Noble were green. The fruits were about the size of Sir Joseph Paxton, firm, and briskly flavoured. The Committee recommended that the variety be grown at Chiswick, for comparing its earliness with other varieties there. Four baskets of splendid fruits of Noble, La Grosse Sucrée, Sir Joseph Paxton, and Sharpless were sent from Frogmore. They were greatly admired, and a vote of thanks was recorded from them. The large fruits of the American variety Sharpless were tasted, but a good deal of sugar and cream would be needed to make them enjoyable. Mr. Tudway, Lower Berkley Street, sent pale, unshapely fruits of Auguste Nicaise, the heaviest weighing 2½ ozs. They were of fair quality, and a vote of thanks was passed for them. Mr. E. D. Whitehouse, Pelham Lodge, Chester Road, Kidderminster, sent fruits of a new Strawberry, Whitehouse's Seedling. They were large, but in a measure spoiled by cotton wool adhering to them. Recommended to be grown at Chiswick.

Mr. James Hudson sent from The Gardens, Gunnersbury Park, a box of very fine and well coloured fruits of Lord Napier Nectarine. They were gathered from a tree spreading 26 feet by 13 feet, bearing 250 fruits. A cultural commendation was unanimously awarded. Mr. G. Wythes, Syon House Gardens, sent seven dishes of ripe Cherries, grown on trees against walls without protection, the varieties being Early Rivers, Black Eagle, Waterloo, Tartarian, Frogmore Bigarreau, Belle d'Orleans, and Governor Wood. They well indicated the earliness of the season—the purpose for which they were sent. Mr. Wythes also sent Potatoes and Peas from the open ground, the dish of Duke of Albany Peas being very fine, and a cultural commendation was awarded for them, with a vote of thanks for the collection.

Messrs. Cooper, Taber & Co., Rivenhall, Witham, Essex, sent a dish of Duke of York Peas from a sowing in the open on February 10th. This variety was granted \*\*\* in the Chiswick trials last year, and an award of merit was passed by the Committee. Messrs. M'Hattie & Co., Chester, sent samples of M'Hattie's Hardy Winter Lettuce, large, but somewhat coarse, and no award was made. Mr. H. C. Princep, The Gardens, Hogg House, Buxted, Uckfield, sent twelve dishes of Peas in good varieties, admirably grown, and a cultural commendation was unanimously awarded.

FLORAL COMMITTEE.—W. Marshall, Esq. (in the chair); Messrs. J. Laing, R. Dean, H. B. May, J. Jennings, H. Turner, W. Bennett-Poe, C. E. Shea, C. Noble, G. Paul, E. Mawley, J. D. Pawle, P. Barr, H. Herbst, G. Gordon, R. Owen, and Rev. H. H. D'Ombrian.

Messrs. P. Barr & Son, Long Ditton, sent a large collection of hardy flowers. The best of these included some good Delphiniums, Iceland Poppies, double and single Pæonies, Irises, Lilliums and hardy Geraniums. The Spanish Irises were specially good (silver Banksian medal). Messrs. J. Cheal & Sons, Crawley, had a small collection of hardy flowers, comprising Pæonies, Aquilegias, Pyrethrums, Campanulas, and Papaver nudicaule in variety. Three boxes of Viola blooms were also sent by Messrs. J. Cheal & Sons. The flowers were fresh and bright, the best being Trentham Purple, Archibald Grant, Duchess of Sutherland, and Bloomer (bronze medal). Messrs. G. Paul & Sons, The Old Nurseries, Cheshunt, had some charming double Pæonies, which made a bright display. The most conspicuous varieties in this collection were Arethusa, Madame Loise, Lady Lenora Bramwell, Duchesse de Nemours, Prince Imperial, Mols Bouchardet, Jeanne d'Arc, and Marie Lemoine. Awards of merit were adjudged the three last named, which are described elsewhere. The same firm sent three boxes of cut Rose blooms, including the comparatively new Bourbon variety, Mrs. Paul (silver Flora medal).

Messrs. J. Veitch & Sons sent a plant of Abies orientalis aurea, for which a first-class certificate was awarded. This Conifer is described elsewhere. A basket of Cleome pungens was also sent by Messrs. J. Veitch & Sons. Lord Penzance, Eashing Park, Godalming (gardener, Mr. Baskett), sent a beautiful collection of hybrid Sweet Briars. The best of the varieties shown included Flora MacIvor, Diana Vernon, Effie Deans, Clara Mowbray, Minna, and Matilda Marchmont. These fine plants are sure to become popular when sent out to the public. Awards of merit were adjudged for the two last named varieties. Messrs. Hubert & Mauger, Doyle Road Nurseries, Guernsey, were accorded an award of merit for Gladiolus delicatissima superbissima, a pretty variety. G. F. Wilson, Esq., Weybridge, sent some Calochortus blooms cut from the open border (vote of thanks). Messrs. W. Paul & Sons, Waltham Cross, had a box of cut Roses, including the recently introduced Lorna Doone. This is a Bourbon variety, of an attractive appearance and very free flowering. The Rev. W. Wilks, Shirley Vicarage, staged blooms of a Poppy supposed to be a hybrid from P. orientale and P. rupifragum, but no award was made. Mr. C. J. Van Tubergen, Haarlem, Holland, sent blooms of Iris Lorteti and I. hispanica Mongolian, a showy yellow variety. For the first named Iris a first-class certificate

was awarded. Mr. Martin R. Smith, Hayes Common, sent blooms of Carnation Sir Charles Freemantle, for which an award of merit was adjudged. Blooms of *Richardia aurata* were sent by Mons. J. B. Deleuil, Sainte Anne, Marseilles, and an award of merit was accorded. A description of the spathes will be found elsewhere. Messrs. W. Balchin & Sons, Church Road, Brighton, sent flowers of their showy *Pyrethrum Jubilee*, and Mr. W. Smith, Basing Park, Alton, had a flower of *Lilium japonicum rubrum*. Mr. G. Prince, Oxford, sent boxes of cut Roses, comprising charming blooms of *Gustave Regis*, *Clara Watson*, *Prince of Wales*, *Miss Ethel Brownlow*, *Catherine Mermet*, and other choice Tea-scented kinds (silver medal). Mr. C. T. Druery, Fernholme, Forest Gate, had a picture of "A British Fernery," and a plant of *Athyrium filix-fœmina* var. *congesto-cristatum*, which was found growing wild in Ireland last year.

Mr. R. Dean, Ealing, exhibited a number of new border Pinks in variety, and the strain was commended. Mr. C. Turner, Royal Nurseries, Slough, sent a box of laced Pinks, and an award of merit was given for *Empress of India*, a charming variety. This is described elsewhere. Mr. G. Fry, Lewisham, secured an award of merit for *Carnation Annie Sanders*, a fine variety. Mr. A. McMillan, Trinity Cottage, Edinburgh, sent a dozen *Chrysanthemum* blooms of good size. Mrs. Irving Clarke, Middle Lacroix, G. Wormig, and W. Coles were the best, but the flowers looked out of season. Messrs. Dobbie & Co., Rothesay, had *Sweet Williams* (cultural commendation) and a number of *Viola* blooms.

Mr. Anthony Waterer, Knap Hill Nursery, Woking, showed two boxes of hardy *Rhododendrons* and a box of late flowering scented *Azaleas*, which comprised a very charming exhibit (silver Banksian medal). For twelve hardy *Rhododendrons* Mr. Wythes, gardener to the Duke of Northumberland, Syon House, Brentford, the only competitor, was awarded the first prize. Messrs. E. D. Shuttleworth & Co., Peckham Rye, and Flect, Hants, arranged a beautiful group of herbaceous plants, prominent amongst which were Iceland Poppies, *Violas*, *Lychnis viscaria splendens plena*, *Agrostemma hybrida*, and a small collection of *Roses* (bronze medal). The same firm also staged an attractive collection of flowering and foliage plants, including *Ferns*, *Crotons*, *Dracenas*, *Orchids*, and *Liliums*. A small group of *Begonias* was shown by Messrs. J. Laing and Son, Forest Hill, and formed one of the best features of the Show. The best varieties were *Bicolor*, *Alfred de Rothschild*, *Duke of Fife*, *Crimson Fringe*, *Virgin Queen*, *Lydia*, *Countess of Dudley*, *Ernest Cook*, and *Orange King*. Awards of merit were adjudged for three varieties which are described elsewhere. Mr. J. Hudson, gardener to Messrs. de Rothschild, Gunnersbury House, Acton, staged a box of *Ixora Westi*, and also one of *I. Prince of Orange*. Mr. J. Perry, gardener to J. C. Tasker, Esq., Middleton Hall, Brentwood, exhibited *Cannas* and *Roses*. Amongst the best of the former were *Francisca Kruger*, *Honorable Edith Gifford*, *Wm. Allan Richardson*, and *Madame Lambard*. The *Cannas*, which were very beautiful, comprised *Paul Bruant*, *François Corbin*, *Madame Crozy*, *Admiral Corbet*, *Antoine Chantier*, and *Victor Hugo* (silver Banksian medal).

**ORCHID COMMITTEE.**—Present: H. J. Veitch, Esq. (in the chair); Dr. Masters, Messrs. J. O'Brien, Dr. B. Crawshay, H. M. Pollett, Edward Handley, J. Douglas, E. Hill, T. B. Haywood, and S. Courtauld.

As already mentioned *Orchids* were not extensively represented. Messrs. W. L. Lewis & Co., Southgate, N., sent a small, well arranged group. *Cattleya Mendelli*, *C. Mossiæ*, *Lælia purpurata*, *Thunia Marshalliana*, *Oncidium ampliatum majus*, and the pretty *Cypripedium porphyreum* were noticeable in this contribution. Messrs. Hugh Low and Co., Clapton, also sent a collection of *Orchids*, tastefully arranged, and for which a silver Flora medal was recommended. *Cattleya Mendelli* and *C. Mossiæ* in variety were conspicuous in this group, as also was a plant of *C. gigas*. Other noticeable plants were *Cypripedium voluteum*, *C. Veitchi*, *Disa grandiflora*, and *Cattleya Schilleriana* *Regnelli*, a pretty form (silver Banksian medal). T. Statter, Esq., Stand Hall, Manchester (gardener, Mr. Robert Johnson), sent a collection of cut *Orchids*, comprising remarkably fine spikes of *Cattleya gigas delicata*, *C. gigas*, *Stand Hall* var. (very fine), *Lælia purpurata gigantea*, and *Lælia grandis tenebrosa*, *Stand Hall* var.

Captain Hinks, Terrace House, Richmond, Yorks, sent a small plant of *Masdevallia Veitchiana-Estradæ*, a little orange coloured flower. Messrs. F. Sander & Co., St. Albans, had a small collection, including *Lælia Oweniana* (*L. Dayana* × *L. xanthina*), *Cypripedium macrochilum*, *Batemannia Burti*, and *Dendrobium hercoglossum*. Messrs. F. Sander & Co. were awarded a silver-gilt medal for the best seedling *Orchid* not exhibited previous to January, 1893. This was a splendid hybrid named *Lælia hybrida Maynardi*, which attracted much attention. It is the result of a cross between *Lælia pumila Dayana* and *Cattleya dolosa*. The sepals and petals are rosy purple with darker veins; the lip is a rich purplish maroon, the centre being lighter. A. H. Smec, Esq., The Grange, Wallington (gardener, Mr. G. W. Cummins), had a box of cut *Lælias* and *Cattleyas* (silver Banksian medal). There were some very good forms amongst these, the best being *Cattleya Mendelli Hackbridgensis*, *C. Mossiæ Wageneri*, and *C. Mossiæ* (Mrs. Smec's variety). A plant of *Lycaste Deppei viridis*, full of flower, was also shown by Mr. Smec.

#### CERTIFICATES AND AWARDS OF MERIT.

*Abies orientalis aurea* (J. Veitch & Sons).—This is a graceful Conifer of neat growth. The young shoots are of a pleasing yellow, which enhances the value of this *Abies* considerably (first-class certificate).

*Begonia Ernest Cook* (J. Laing & Sons).—A splendid double variety, the flowers being full and of a rich crimson shade (award of merit).

*Begonia gigantea* (J. Laing & Sons).—A double variety with well-formed flowers of a pale salmon pink tint (award of merit).

*Begonia Richard Dean* (J. Laing & Sons).—A beautiful double flower of a bright orange scarlet colour (award of merit).

*Carnation Annie Sanders* (G. Fry).—This is a charming variety with bright cerise coloured flowers of excellent form (award of merit).

*Carnation Sir Charles Freemantle* (Martin R. Smith, Esq.).—A very fine bright coloured seedling *Malmaison* *Carnation*. The flowers are full, and of a brilliant red colour (award of merit).

*Gladiolus delicatissima superbissima* (Hubert & Mauger).—A pretty form, useful for decorative purposes. The flowers are medium-sized, white, the centre of each petal being blotched with bright crimson (award of merit).

*Iris Lorteti* (C. G. Van Tubergen, jun.).—This is a very distinct species. The flowers are large, the falls being dark grey covered with minute brown spots. The standards are whitish tinted rosy purple, dark veins (first-class certificate).

*Pæony Jeanne d'Arc* (G. Paul & Son).—A charming double variety with flowers of a large size. The outer petals are tinted rose, the centre being cream (award of merit).

*Pæony Marie Lemoine* (G. Paul & Son).—A large double flower of chaste appearance. The lower petals are blush, the centre ones white with a cream base (award of merit).

*Pæony Mons. Boucharlet* (G. Paul & Son).—A very full flower with bright pink petals, lighter coloured margins (award of merit).

*Pink Empress of India* (C. Turner).—A pretty laced variety, the flowers being of good form, and the rich rosy purplish markings well defined (award of merit).

*Richardia aurata* (J. B. Deleuil).—The spathes of this *Richardia* are pale yellow with a dark blotch at the base of the throat (award of merit).

*Sweet Briar Matilda Marchmont* (Lord Penzance).—A charming variety, with pale pink flowers and light centre (award of merit).

*Sweet Briar Minna* (Lord Penzance).—The flowers of this variety are large and of a delightful rosy pink shade (award of merit).

#### THE LECTURE.

At the usual afternoon meeting at the Drill Hall on Tuesday, a very interesting and instructive paper on "Hardy *Rhododendrons* and *Azaleas*," was read by Sir John D. T. Llewelyn, Bart. Mr. Bennett Poë occupied the chair. The essay was admirably illustrated with two boxes of *Rhododendrons* and one of *Azaleas* sent by Mr. Anthony Waterer, and also by some photographs of plants which are growing in the gardens of Lord Swansea, near the town of that name.

The essayist briefly reviewed the early history of the *Rhododendron*, saying to what countries they were indigenous and where the most common and earliest known species were found, Asia Minor giving us the old *R. ponticum*, for example. Winter frosts, it was remarked, were not detrimental to the plants, but those during the months of April, May, and June, which often proved so disastrous to the *Rhododendron* in this country. The growths at that period of the year were, he said, in a succulent state, and were thus peculiarly susceptible to the frost. It was the Himalayan species that the essayist dealt with at greatest length, as affording such a diversity of colours in the blooms during the spring months and such fine foliage in the winter. Many of the species were not hardy, but if seeds which had been gathered from species growing at an elevation of 9000 feet above the sea were sown, the plants would most probably prove to be perfectly hardy when raised in this country. As an example of this reference was made to the magnificent collection of Lord Swansea, almost the whole of the plants having been raised from seeds sent direct from India.

An instance of the hardiness was given, *R. Thomsoni* being the example, which, after having set its bloom buds, was subjected to three weeks' continuous frost, and was not touched. On the contrary, on the day immediately succeeding that on which the frost ceased the buds commenced to gradually expand, and produced perfect pips and fine trusses. It was a fallacy, now almost entirely removed, to think that it was essential that the soil should be of a peaty nature to grow *Rhododendrons* to perfection, for they would thrive in any fairly moist loam, with the exception of one which contained lime, this acting as a poison on them; neither would they grow well in a dry clayey soil. In such a mould it would be advantageous to fork in some dead bracken, which had a very good effect on the plants. Referring to the natural habit of the *Rhododendron* to hang down its branches to afford protection to the roots, the essayist pointed out how easy this rendered the process of layering the shoots.

In briefly referring to the *Azalea* Sir John Llewelyn said it was no longer looked upon by botanists as a distinct genus from the *Rhododendron*, but was now very generally classed with it. The old species of our gardens was *A. pontica* and what were commonly called the Ghent varieties, which though small in the pip were most useful when their sweetness and hardiness were taken into consideration. The varieties of *A. indica* were not perfectly hardy, though *A. indica alba* sometimes bloomed profusely in the open ground in favourable positions and in a propitious season. Brief reference was made to *A. mollis*, which though quite hardy was mostly seen in pots as it had proved so useful for forcing purposes.

An interesting discussion followed the paper, the question of the benefits of cow manure as a mulch for *Rhododendrons* being raised, and the essayist's opinion asked thereon, but as the lecturer had not

tried it personally he did not feel confident in recommending its general use.

A vote of thanks to Sir John Llewelyn for his admirable paper closed the meeting.

### A DAY IN THE DUKERIES.

WHEN I was living within the purlieus of the Cinque Ports the question used often to be mooted by visitors, Which are the Cinque Ports? and it was somewhat odd to find that even old inhabitants were very much at sea (as perhaps they ought to have been) as to which were the five included in the term. "Oh," it used often to be said, as if the informant was running out a sounding line, "there are Sandwich, Deal, Dover, and —," then came the halt. Were Rye and Winchelsea or Hastings to be included? and I believe that very many who live in that favoured locality can hardly tell. Indeed, I think that probably a Lord Warden may have been ignorant of the possessions over which he ruled.

his untiring zeal we are to hold the provincial show of the N.R.S. this year at Worksop, the smallest town in which it has ever been held. If he who kills fat bullocks should himself be fat, it also follows that anyone who would undertake to introduce the National Rose Society into his neighbourhood must of necessity be a rosarian, and thus I was prepared to find that whatever else might be grown at Gateford, the chief object of interest would be the rose. Nor was I disappointed. The garden is a large old-fashioned one; one mark of this being that the walls are hollow and capable of being heated, according to a practice which was once, when glass was dear, commended to those who could afford it, but one which cheap glass and better knowledge has completely done away with. But as I have said, it was of course too early to say much about the condition and prospects of the Rose itself, but the plants looked well and healthy, and there were large battalions which ought to stand Mr. Machin in good stead on the day of battle.

These are in what may be called the Rose garden outside of the walled garden, and on a slope where they are well sheltered, although it is

FIG. 83.—THE PALM HOUSE AT WELBECK.

It is very much the same with regard to the Dukeries. What are the estates so called? "Oh, there is Clumber and Welbeck," and then often comes the hesitation. Sometimes Trentham is called in, sometimes Chatsworth—very far wide of the mark, while the difficulty is increased by the fact that there are now only the two above mentioned, the third estate (Thoresby, which once belonged to the Dukes of Kingston) having passed into the hands of Earl Manvers. These three noble estates, lying close by one another, include a large slice of the northern part of the county of Nottingham, and are in some of their characters unique.

When my kind friend and host, Mr. H. V. Machin of Gateford Hill, Worksop, proposed a drive through the far-famed Dukeries it opened out to me visions of enjoyment which I am bound to say were amply fulfilled. One's imagination—and I have not a very vivid one—conjured up the stories of Robin Hood and Little John. One thought of Friar Tuck and all the dramatis personæ of Scott's bewitching story; and then there were realities to see—princely houses and domains, grand gardens and verdant glades and hoary forests, for were there not Oaks to be seen which had existed there before the Conquest? And as the weather was fine, as it has been generally during this extraordinary season, one's anticipations of enjoyment rose high, but high though they were they were amply justified by results.

But before I say anything of the day's proceedings I would like to say something of the place from whence we made our start. Mr. Machin is, as many readers of the *Journal* know, an energetic rosarian; through

only a portion of a field which has been brought into cultivation for this special purpose. Here there are about 7000 cut-backs, and there are 12,000 stocks for next year's budding, besides two or three thousand dormant buds on dwarfs and 800 to 1000 on half-standards. Here there is an army with which some of our combatants will have to take account. I may add, too, that Mr. Machin is thoroughly alive to all the requisites for showing. The place for setting up his blooms is admirably arranged, and every requisite amply provided, so that I think we may fully expect to see him taking up a prominent position.

Our start was a false one; one of the horses took it into his head to gib, and threw himself down on the pole, to the imminent danger of snapping it. However, the coachman was master of the situation, and by very good chariotteering and a judicious use of the whip he succeeded in getting them off, and the mare proved herself, like many an ill-tempered one, a thorough good one to "go." She did not try her tricks again, and behaved well throughout the day.

Although we desired to have a run through the Dukeries, which involved a round of about thirty-five miles, we could not possibly hope to see everything of interest, and I believe as horticulturists if nothing else we were inclined most to Welbeck. On our way we had a view of the cricket ground where the N.R.S. is to hold its Show, a convenient and suitable spot close to the town, passing by Worksop Manor. Welbeck was, however, the Mecca of our pilgrimage. We might see the environments of Clumber and Thoresby, but we felt that there was a magnetic influence in Welbeck that drew us irresistibly

there. And what a princely place it is! It is true the house cannot compare with either Chatsworth or Belvoir, but if you were told by your guide that you were in the midst of some small principality, like those of Germany, you would not feel surprised. The outbuildings and stabling, the domestic offices, and the chapel give you the idea that you are in some very flourishing village, while all that pertains to the breeding and rearing of racehorses is carried out in the most complete manner. I am not a horsey person, but I can admire beauty wherever I see it, and what more beautiful thing is there than the racehorse? Here then we first proceeded, and in the stables saw those three noble sires St. Simon, Johnny Morgan, and Donovan. The former of these I had a special interest in, as he was bred in my own county by the late Lord Falmouth, and is supposed to be the best horse in the world, and certainly a more beautiful creature it is impossible to imagine. The Duke is pleased to tell a story of an enthusiastic American horse trainer who came over to England for no other purpose than to see this famous horse, and when he had his desire gratified took the next steamer and returned home. He never ran for the Derby owing to the death of his noted owner, whom all horticulturists will connect with his brother, the Hon. and Rev. J. Townsend Boscawen. Having thus gratified what I hope may be considered a laudable curiosity, and have seen the perfect arrangements made for the brood mares and their foals, we sought the gardens, and there under the guidance of Mr. Horton, who has for some years ably presided over them, did what we could in a short time to see how things were done. I may at once say that the idea they gave to me was their thoroughly practical character. There are no such grand houses as at Chatsworth, but the place, by its size and the character of its cultures, reminded me much of Frogmore. Let me give one illustration of its extent. There is a quarter of a mile of Apricot wall protected by glass cases. These were in splendid condition, full of fruit, and bushels of thinnings had already been taken off, and another thinning had to follow. Vines, Peach houses, Fig houses were, if not on such a scale as this, quite in correspondence with the princely character of the place.

It is well known that the late Duke of Portland was, to say the least, a very eccentric person. Many stories are told to illustrate this, and they go to show that notwithstanding these oddities, he was a kind-hearted and thoughtful man. One memorial of his curious ways remains in the subterranean passages at Welbeck. He did not like to encounter people, consequently had the passages built that he might avoid them. One of these is two miles in length, and leads to the neighbouring town of Worksop. One of the outcomes of this is what is called the underground rosery and Palm house (fig. 83). Of course they are not absolutely so, as they must be open to receive light and air, but you reach them by an underground passage, and leave them in the same way. Roses are planted in the beds and run up the pillars. Maréchal Niel and William Allen Richardson were in full bloom. The Palm house does not contain those tall plants which have a permanent place there, as at Kew or Chatsworth, but plants which would come in suitably for decoration of halls and rooms on feast days, and could be easily moved about. Besides Palms the house contained Crotons, Dracenas, &c., all in excellent health. Another somewhat unusual feature interesting to Rose growers was the attempt to convert what is called the Bachelor's Gallery into a Rose arbour. It is about 150 feet long, covered with glass, and at intervals of 8 or 10 feet are placed large square boxes in which are planted a Tea Rose. This is trained up towards the roof, and consequently the plants have now the appearance of climbing Roses. Here were Catherine Mermet, The Bride, Climbing Niphetos, Souvenir d'un Ami, Marie Van Houtte, William Allen Richardson, and, in fact, all the best Tea and Noisette Roses. The plants numbered about sixty, and there is no doubt if they succeed it will be very pretty, but I think the success is doubtful. The plants are a long way from the glass, and I fear that the shoots before they reach it will become drawn and attenuated, and so the blooms be of little value; but it will I should imagine suit the Noisettes or Teas of the Gloire de Dijon class, but I doubt very much whether Catherine Mermet and the genuine Teas will thrive under what must be to them an unnatural state of things.

It is not always in such large places that we find an appreciation of newer introductions, but they are thoroughly recognised here, and all the best things in fruit, vegetables, and flowers are appreciated at Welbeck. Outside, in the terraces and pleasure grounds that overlook the lake there are to be found the choicest shrubs and trees, so that one feels that there is a real interest taken in the productions which fill the place in all directions.

I have not ventured to attempt anything like a full account of the gardens for two reasons—one is that the time at my disposal was too short to attempt taking anything like extended notes; the other is that I believe the general reader looks for such a description as may give him a general idea of the place rather than for detailed accounts of the number of houses, and their size. I do not think anyone can go through these extensive gardens and pleasure grounds without being struck by the perfect order and cleanliness which pervade all departments. No American blight here, as I have seen it in places claiming to be well looked after; no mealy bug in the stoves or aphides on the Roses, while vigour and health are the characteristics of the various things grown under Mr. Horton's intelligent care. Few persons have an idea of the amount of forethought necessary to manage a place like this. It is not, as some suppose, a mere routine of work. Seasons vary so that one year is no indication of another; it is of no use, for instance, looking back to the diary of 1892 to know what ought to be done now, in a

season fully a month in advance of it. Happily, Mr. Horton is not required to make "bricks without straw," and he has an efficient and sufficient staff under him.

After leaving Welbeck we drove on through the remains of Sherwood Forest, which must have been a grand place when the giants whose skeletons now adorn it were in their full beauty. Nowhere, that I can recollect, are there the remains of so large a number of these megatheriums of the forest to be found. We meet with isolated cases, such as the Headcorn Oak in the churchyard of that village, and the Fredville Oak in the demesne of that ilk in my own county of Kent; but here one sees them congregated in dozens, and these are of course but the residue of what it once contained. Probably we might have seen them to greater advantage, but then it was whispered to us "You would have had the flies," and I know something of what a nuisance they are, especially when you settle down to luncheon, as we did near the old tree that is called Robin Hood's Larder. We passed by Clumber and Thoresby, only obtaining a passing glance at them, for our time was quite run out, especially as there was a meeting of the Workshop Horticultural Society to be held in the evening to settle the details of the provincial Show, and so we hurried on, passing through the stately entrance of Thoresby, and to the town of Worksop, after having had a most successful and enjoyable day, very much enhanced by the thoughtful consideration and kindness of my host, to whom I owe it that amongst the red letter days of recent years must be added this one of "a day in the Dukeries."—D., Deal.

## PELARGONIUMS AT LEWISHAM.

### SINGLE ZONAL PELARGONIUMS.

WHEN looking over the very fine collection of these which Mr. H. J. Jones has in his nursery at Lewisham recently, I was enabled to make a selection of a dozen that seemed to me to be of exceptional excellence. Though not all perhaps new, still most of them show marked advance, have very fine pips, free blooming habits, and beautiful alike for ordinary greenhouse decoration or for the making of exhibition plants.

In this latter direction especially some change is much needed, for one tires of seeing at exhibitions so frequently old varieties that have done duty year after year. The following are very good:—Mr. D. B. Crane, a brilliant scarlet of great size and fine form; Mr. A. H. Needs, a beautiful soft light salmon, large, rounded, and of great excellence; Mr. H. Shoesmith, rich crimson scarlet, with pure white eye, very striking variety; Mrs. W. Wright, wonderfully free, flowers of a bluish magenta hue, the richest of its peculiar shade yet seen; Flamingo, a wonderful bloomer and a fine bedder, flowers scarlet, shaded orange and plum, a charming variety; Galatea, lovely shade of salmon rose, having a white blotch on the upper petals; Lady Brooke, a white-flowered variety, but there is a soft touch of pink in the centre of the flowers.

Lord Salisbury has flowers of the very largest size and of great substance, colour rich madder shaded magenta, also a fine winter variety. Maud of Wales, a pretty lilac pink, having very fine flowers; Duchess of Portland, the very best of the rich rose pinks, a flower of exceeding beauty; Sunray, clear orange scarlet, one of the most striking of this shade of colour; Rose Du Barry, soft rosy salmon shade, fine pips, and very free; and to make up an odd number I add, for a beautiful pure white, Sir Percival, a very perfect flower, and is of great value for its purity in the winter. Mr. Jones has a good stock and a wonderful variety. The selection made was from young plants all in bloom, and thus afforded the best opportunity for comparison.

### DOUBLE ZONAL PELARGONIUMS.

In this section of one of our most useful of flowering plants we find undoubted progress is made from time to time, not merely in the habit of the plants but also in size of pip and variation of colour in the flowers. A very interesting collection of these also at Mr. Jones's nursery in full bloom enables a good selection of the best to be made. The beauty as well as exceeding variety found in both single and double forms makes one to wish for opportunities to grow them well, for how rarely after all do we see plants at exhibitions that do justice, or in perfection show what specimen plants should be.

All the varieties are easily grown, and when large plants are in profuse bloom they are wonderfully attractive. At many exhibitions now it is almost alone left to Begonias to give colour; but charming as these are they even become monotonous if presented in too great abundance. Then the flowers of double Zonal Pelargoniums are of such marked value for cutting purposes. Perhaps this particular value materially helps to discount their growth as specimen plants.

The following presents a first-class selection, and some striking novelties:—Raspail Improved, a very large flowered form of the fine market variety, brilliant in colour, one of the largest pips produced; Colossus, rich reddish crimson, wonderfully fine; Mr. J. S. Phillips, colour a striking deep salmon; Mr. J. Surman, blush pink, delicately tinted and refined; Golden Rain, bright orange scarlet, the most strikingly yellow of any yet seen; Lydia, white tinted cream, having a centre of reddish pink; White Abbey, the very best pure white, blooms freely and has a good habit; Althea, rich cerise scarlet; Béaute Poitevine, very compact growth, flowers clear salmon, on stout short footstalks; La Contable, deep pink; Maggie Hallock, soft pure salmon; M. Bruant, semi-double, clear scarlet, and Sombre Horison, intense deep crimson, compact habited. Not in all cases are the English appellations

so pleasing or mellifluous as are the French ones. Common personal names are often hardly worthy of application to beautiful flowers.

#### IVY-LEAF PELARGONIUMS.

The variety *Ryecroft Surprise*, which is referred to with such approbation in your report of the Royal Botanic Show, thoroughly merits all praise. It may be said to present a distinct departure from the old long-jointed and loose-growing habit of other varieties; indeed, the fine specimen plants which Mr. Jones exhibited at the Temple Show fully demonstrated what a first-class plant it is to grow for exhibition purposes, for in that respect it vies in compactness of habit and floriferousness with the best Zonals.

I saw the entire stock of the variety the other day at Lewisham, and noted that the same remarkable short-jointed habit characterised every plant, however grown. The flowers are of the clear bright pink hue, so much valued in the market, and very double and of great size. Altogether we have in this form the best break made in the Ivy-leaf section, so far as habit is concerned.—A. D.

#### THE SPARROW—FOR AND AGAINST.

It is now many years since I attributed the destructiveness of sparrows to eating artificial food or scraps from the table. In my youthful days economy was strictly carried out with rich and poor alike, consequently there were few or no scraps. All that is changed now, and a large quantity of good food is thrown away. This food feeds rats, mice, and sparrows, and the salt it contains causes thirst.

Sparrows peck fruit buds now, whereas fifty years ago, when they had access only to natural food, did not meddle with the buds. At all events they are more destructive on buds near towns than in the country. I never saw the sparrows peck Croci. The yellow Crocus I have seen torn to pieces, but the depredators were slugs, and not sparrows. Oats when beginning to ripen are reduced in bulk by them, and building their nests in some places are unsightly and often stop water pipes, all of which tends to raise the ire of many individuals who threaten their destruction.

My garden is between two others full of pests, the occupiers of which take no steps whatever to reduce, consequently I have to keep up a perpetual warfare to have the slightest chance to enjoy either fruit or flowers. The sparrow comes to my aid. This year the trees, bushes, and hedges were swarming with various caterpillars. The sparrows for the past fortnight have kept up a continual warfare with them, with the result that the verdure of all mentioned is preserved. The numbers were so great that had the pests not been destroyed scarcely would a vestige of leaf been left.

On May 13th I saw a sparrow pick from the ground a large grub of the daddy-longlegs and flew to a Morello Cherry tree. In less than half a minute it killed six caterpillars and fed its young with them. It then flew down and pecked heartily at the blades of grass. All this occurred in less than five minutes and within 6 feet or less of me.

The foregoing are glimpses of both sides of the question. Let him say, who can do so wisely, whether the sparrow should live or die.—W. T. B.

[Mr. Witherspoon sends a communication on this subject, but it did not arrive in time for insertion in our present issue. He disclaims any intention of discourtesy to "W. R. Raillem" (page 444), and regrets if he conveyed that impression.]

#### A VISIT TO WALTHAM.

WALTHAM is a region which may be described as equally interesting to the lover of Nature, the horticulturist, the antiquary, and the historian. In Waltham Abbey, it is generally supposed, repose the bones of the heroic English king who fought and died at Hastings. Theobald's Court, which is in the immediate vicinity, was the residence of King James the First of England and Sixth of Scotland; the famous Cross at Waltham was consecrated to Eleanor, an English queen; the chimes of Waltham Abbey suggested to Tennyson, when he was residing at High Beach, the immortal passage in his "In Memoriam" beginning—

"Ring out, wild bells, to the wild sky,  
The flying cloud, the frosty light;  
The year is dying in the night;  
Ring out, wild bells, and let him die."

I was chiefly attracted Walthamwards by the magnetic personality of a venerable and gifted horticulturist, Mr. William Paul, F.L.S., who has his world-famous rosarium there. Most gladly did I comply with his kind invitation to pay him a visit during the flowery month of May. Waltham is easy of access from the modern Babylon; if you are fortunate enough to get a fast train at Liverpool Street Station you may be there in half an hour. Such, however, was not my good fortune, for my train stopped at nearly every station; yet the time passed quickly, for the morning was fine, and there were many objects of interest by the way.

Arrived at Waltham I found the veteran rosarian awaiting me at the station; and he at once conducted me through his great rosarium. There were born those exquisite Roses which I am proud to possess, the *Beauty of Waltham*, the *Pride of Waltham*, *Magna Charta*, *Ella Gordon*, the *Crown Prince*, and many others of equal interest and renown. There is perhaps in Europe no greater raiser of new and valuable Roses than Mr. Paul—a fact adequately realised and admitted by all the leading European rosarians of the last half-century, such as Guillot,

Verdier, Levet, Lacharme, Margottin, Labbay, and Liabaud, many of whom have been his intimate personal friends. He has many interesting reminiscences of these, of which one of the most memorable is connected with the first introduction by himself into England of the "*Maréchal Niel*." Another celebrated and exceedingly valuable French Rose which Mr. Paul was the first to popularise in this country, where it has reached an absolutely universal circulation, is *Gloire de Dijon*, a flower possessing at least five different shades of colour, of exquisite fragrance, immense substance, and marvellous durability. Among the famous Roses of which Mr. Paul has been the "raiser" (for that is the technical and unbecoming term) I may mention *Beauty of Waltham*, *Lord Clyde*, *Duke of Edinburgh*, *Duchess of Albany*, *Duchess of Bedford*, *Glory of Waltham*, *Magna Charta*, *Marchioness of Lorne*, *Pride of Waltham*, *Queen of Queens*, *Star of Waltham*, *Ella Gordon*, *Crown Prince*, and *Little Gem*, the last-mentioned being a crimson Moss of remarkable beauty. Of his more recent productions, which he showed to me at Waltham in magnificent bloom, are *Sappho*, *Clio*, *Corinna*, *Duke of York*, *Salamander*, and *Princess May*. His *White Lady*, a daughter of *Lady Mary Fitzwilliam*, is a Rose of remarkable substance, size, and beauty, though of dwarf habit (a great recommendation); it is exceedingly prolific, and its fragrance is that of the *Malmaison* *Carnation*. I had recently the pleasure of highly recommending this superb Rose for extensive cultivation to Mr. Harry Turner, when he was showing me his "*Royal Nurseries*" near Windsor Castle, where he grows to perfection countless masses of *Regal Pelargoniums* and *Azaleas*, 70,000 plants of the finest *Carnations*, and 200,000 *Rose trees*. I have on the other hand been commending to Mr. Paul, having seen it in all its integrity at the *Royal Nurseries* (well worthy of such a name), Mr. Turner's very beautiful and profusely floriferous *Polyantha Rose*, which I doubt not the *Waltham rosarian* will do much to popularise.

During my memorable visit to his rosarium Mr. Paul gave me much interesting information regarding the origin or parentage of his Roses. He told me, for example, that *Beauty of Waltham* and the *Duke of Edinburgh* were raised from seed of *Général Jacqueminot* between 1862 and 1868. His *Duchess of Albany* is, if that be possible, an improved *La France*, and owes its characteristics, which cannot be over-valued, to that divine Rose, which, like some of our *Orchids*, *Cattleyas*, *Lælias*, and marvellously lovely *Dendrobiums* (of which perhaps the fairest, sent to me by the *Duchess of Sutherland*, are glowing before me as I write) almost too beautiful for earth. My open-air substitutes for those tropical flowers at the conservatory are *Irises* and *Aquilegias*; of the latter I possess all the most precious and most graceful existing varieties, including *californica*, *cærulea hybrida*, *canadensis*, and *chrysantha*.

Mr. Paul is not a cultivator, unless under glass, of *Japanese*, *Indian*, or *Levantine Lilies*, as at Waltham (to use the language of Mr. Herbert Spencer) they find themselves "out of correspondence with their environments." They do not find there a congenial soul. Here, in *Kirkmaiden*, they simply luxuriate, as if they were in *Japan*, or on the lower slopes of their native *Himalayas*. I grow them among *Roses*, and the effect, I anticipate, will be remarkably fine when *L. longiflorum giganteum* blooms contemporaneously with the *Duchess of Bedford*, *L. candidum* with *La France*, *L. speciosum Krætzleri* with *Victor Hugo*, and *L. auratum* with *Mrs. Paul*.

Roses are by no means at Waltham the predominating speciality, for flowering trees and shrubs of all kinds are everywhere, at least equally conspicuous and impressive. Mr. Paul is especially successful as a cultivator of the *Camellia*, which grows in his extensive Waltham conservatory to a height of 15 feet, and flowers most profusely in early spring. He has also made a special study of the *Hollyhock*, regarding which there is much admirable writing in his "*Contributions to Horticulture*," his latest work, dedicated to Dr. Hogg, an old friend of his, and a great writer on fruit, whom I had the gratification of meeting at Waltham. From him also I received exceptional kindness, which I take this opportunity of gratefully recognising. Mr. Paul resides at Waltham House, not far from his rosarium, a beautifully situated residence, which he purchased from Anthony Trollope, the distinguished novelist, twenty years ago. To it is attached an exquisitely shady, antique garden, full of unexpected beauties, much frequented by genial horticulturists, ring doves, merles, and nightingales; also let me add, by my favourite thrush, who in that region of simplicity, sincerity, and unobtrusive kindness naturally finds himself at home. If a certain sardonic English poet had lived in the present period, and visited Waltham House, he never would have written that memorable deliverance on the happiness of men—

"Man never is, but always to be blessed."

—DAVID R. WILLIAMSON.

#### VENTNOR AND BONCHURCH (ISLE OF WIGHT) SHOW.

MAY 31ST.

THE first Exhibition of the season, and the twenty-seventh of the Undercliffe Horticultural Society, was held on the above date. A more charming place than the grounds of East Dene, Bonchurch, the seat of J. Snowden Henry, Esq., J.P., D.L., could scarcely be imagined. Situated at the foot of high sloping downs and rising precipices, richly embellished with magnificent specimens of choice flowering shrubs and overhanging foliage plants, with sheltering nooks and sloping lawns running down to the edge of the sea made a delightful promenade for the many visitors to the Exhibition.

The Exhibition was held in three tents, and the vagaries of this

exceptional season were noticeable amongst the exhibits. Azaleas were nearly over, Achimenes and Cockscombs well shown, Strawberries, Cherries, Peas and Potatoes from the open very plentiful and fine, Grapes and Melons well coloured and ripe. For six stove and greenhouse plants, Mr. J. Churchill, gardener to J. Snowden Henry, Esq., was first with *Clerodendron Balfourianum*, *Bougainvillea glabra*, *Rhynchospermum jasminoides*, *Ixora Duffii*, *Swainsonia galegifolia alba*, and an Azalea. Mr. F. Orchard, gardener to H. Michell, Esq., J.P., Undermount, Bonchurch, a very close second, having a good plant of *Bougainvillea glabra*, *Rhynchospermum jasminoides*, *Clerodendron Balfourianum*, *Hæmanthus coccinea*, Azalea Triomphe de Paris, and Achimenes Mauve Queen. Mr. W. Sheath, gardener to Miss Mitchell, Macrocarpa, Ventnor, third. For a single specimen stove Mr. Orchard was first with a fine plant of *Clerodendron Balfourianum*. Mr. Sheath was second with *Anthurium Scherzerianum*. For six fine-foliage plants Mr. Churchill was first with three splendid Palms, *Maranta zebrina*, *Pandanus Veithei*, and *Caladium bicolor splendens*. Mr. Sheath second with two good Crotons amongst others. The class for three plants was well represented.

There was a good and close competition for six stove and greenhouse Ferns. Mr. Churchill was first, the best being two *Gymnogrammas* and *Adiantum concinnum*. Mr. F. Orchard was second with a fine *Davallia Mooreana*, *Davallia dissecta*, and *Adiantum cardiochlamum* and *A. cuneatum*; Mr. Russell, gardener to Colonel Goodchild, The Grange, Bonchurch, being third. For a basket of plants Mr. Russell gained first prize. For a group of flowering and foliage Mr. W. Sheath showed a very tasteful arrangement containing some *Odontoglossums*, *Caladiums*, and *Pelargoniums*, and was awarded first, Mr. Cosh, gardener to Marcus B. Huish, Esq., being second. For four Orchids Mr. Churchill was first with *Aërides Fieldingi*, *Cypripedium barbatum*, *Cymbidium Lowianum*, and *Cattleya Mossiae*. Mr. Russell was second, and showed amongst others a very fine and showy plant of *Lælia gigantea*. In the class for Achimenes Mr. F. Orchard was first, the plants in pans well grown and full of flower. For six Cockscombs Mr. F. Orchard was also first with good combs; Mr. Richards, gardener to A. Innes Vine, Esq., second. The Show and Zonal *Pelargoniums* were well represented, Mr. W. Sheath taking the first prize in each class with good, well-flowered plants. In the class for *Calceolarias* Mr. Orchard was first and Mr. Churchill second. The flowering *Begonias* was well shown, Mr. Sheath showing well. The *Fuchsias* were weak, Mr. Sheath showing the best.

For twenty-four cut Roses, Mr. Norton, gardener to the Hon. Mrs. Pelham, was first; and in the corresponding class for twelve blooms Mr. F. Orchard was awarded first prize. For a basket of cut flowers Mr. A. Richards was first with a large basket, arranged with a cross handle. This was drawn for in the evening, and the result was a good round sum added to the funds. Mr. Russell was first for a well arranged hand bouquet.

There was a good exhibition of fruit and vegetables. For Grapes Mr. A. E. Day took the first prize, and Mr. F. Orchard second. For a dish of fifty Strawberries Mr. Orchard showed a fine dish of Laxton's Noble, gathered out of doors, and was awarded first prize; Mr. Churchill was second with a good dish of the same variety. The Tomatoes shown by Mr. Churchill were very fine, and secured the first prize. In the large class for vegetables Mr. Richards was first, Mr. Orchard second, and Mr. Churchill third, all showing well. There were some good dishes of Peas shown, Mr. Orchard being first with William I.; Mr. Richards second with William Hurst. For twelve Potatoes, Mr. Churchill was first with a seedling; Mr. Richards second with Come to Stay. The other classes, including those set apart for amateurs and cottagers, was very creditably filled. Mr. Stears worked hard as the Hon. Secretary to make it a success, and Mr. Fahey was staging Superintendent, and both must be congratulated on the excellent arrangements and display.—C. ORCHARD, *Bembridge, I.W.*

## BATH AND WEST OF ENGLAND AGRICULTURAL SOCIETY'S (GLOUCESTER) SHOW.

HORTICULTURAL DEPARTMENT.—MAY 31ST TO JUNE 5TH.

THIS section of the above was generally acknowledged to be the best ever held by the Society, occupying a larger tent than in former years. The weather was beautiful on the opening day, and the tents were crowded with visitors, making it rather difficult to take notes. On entering, a group of Tree Ferns, foliage and flowering plants, arranged by Messrs. Roberts & Starr of Gloucester, was conspicuous. Next to these came a fine mass of colour from the *Pelargoniums* of Mr. C. Turner of Slough. The plants were well grown, and most profusely bloomed. Adjoining the *Pelargoniums* was a really grand collection of *Gloxinias* from Messrs. Sutton & Sons, Reading. The plants were large and remarkable for the handsome foliage and flowers of great size and splendid colour. Messrs. Heath & Son, Cheltenham, had a very fine collection of flowering plants, including some good Orchids, also foliage plants in great variety, and cut flowers. Messrs. R. Smith and Co., Worcester, staged some of their well known Clematis and splendid Kalmias, *Rhododendrons*, herbaceous flowers, and *Pæonies*, also a fine collection of Iris blooms equal to some of the best Orchids in point of beauty.

At the end of the tent Messrs. R. Veitch & Sons of Exeter erected some rockwork with a pool and waterfall, all arranged with good taste, and occupied with plants suitable for the position, if on a gentle-

man's place. The same firm had a well-bloomed collection of Orchids. Messrs. Kelway & Son, Langport, had some extra good stands of *Amaryllis*, *Pæonies*, *Gaillardias*, *Delphiniums*, and *Pyrethrums*. Roses were well shown by Mr. Conway Jones and Messrs. G. Cooling & Sons, Bath, both putting up good blooms, especially for the time of the year.

Down the centre of the tent masses of stove and greenhouse plants were arranged by the following gentlemen:—Messrs. J. Laing & Son, their stand containing fine *Begonias*. Next came a well arranged group of fine plants from W. R. Baker, Esq. (Mr. J. Aplin, gardener), Hasfield Court, Gloucester. Lord Fitzhardinge, flowering and foliage plants, well grown, and put up with good taste. Sir J. Dorrington (gardener, C. Savegar) had a similar collection. Also Mrs. Gambier Parry (gardener, Mr. Sowray), who had also a grand collection of Stag's-horn Ferns.

Mr. J. Cypher, Cheltenham, had a group of his well known Orchids, making a beautiful display, attracting much attention. T. W. Butt, Esq., Arle Court, Cheltenham, had an excellent collection of Orchids and other plants, reflecting great credit on Mr. Marsh, his gardener. Other highly meritorious groups were arranged by Sir W. F. Guise (gardener, W. Cross), Sir Lionell Darvell (gardener, Mr. Greenway), H. St. V. Ames, Esq. (gardener, W. K. Bannister). The two latter had splendid Carnations in their group. Messrs. Jefferies & Son also staged a collection of Crotons, *Caladiums*, *Begonias* and other plants.

Fruit was not extensively shown, but it was very good. Canon Coventry (gardener, Mr. Frowde) had some extra fine Black Hamburg and Buckland Sweetwater Grapes, also fine Noble Strawberries. Mr. G. Parry had a stand of well-finished Black Hamburg Grapes. Lord Fitzhardinge had some large Melons, Strawberries, and Hale's Early Peaches. C. Lee Campbell, Esq. (gardener, Mr. S. T. Wright), had Hero of Lockinge Melons, Royal George and Early York Peaches; also Glewston Court Tomatoes, all of which were of large size and fine colour. Seedsmen's stands were as usual to the fore outside, attracting much attention.

## LEICESTER PANSY SOCIETY.

JUNE 3RD.

THE second annual Exhibition of this Society was held on the above date in the lecture hall of the Liberal Club, and was opened by Alderman Sir Thomas and Lady Wright before a large number of ladies and gentlemen. The Show as a whole had not the bright appearance of last year, as then many valuable plants were lent "not for competition;" whereas this year the Show was almost entirely for competition. Great headway has been made with the Pansy during the past year, as fully three times the number were exhibited, and they of a far superior quality. In the non-competition exhibit of Mr. W. Sydenham, Tamworth, were many ideal Pansies, including Emma Stuart, James Campbell, Seedling, Tamworth Yellow, A. H. Murray, Thomas Garrett, Tamworth Hero, May Hind, Betsy Kelley, Mr. D. Johnson, Maggie M. Paul, John Coutts, Mrs. W. Sydenham, Tamworth Yellow, Maggie A. Scott, Seedling, Lieut.-Col. Hare, Mrs. W. Sydenham, John Taylor, Arab, Betsy Kelley, Arthur Eaton, Maggie Pender, Tamworth Yellow, Seedling, Alex. Smellie, Edith Crossley, Maggie R. S. Cocker, Tamworth Yellow, Arthur Eaton, Andrew Taiter, Arthur Eaton, and Betsy Kelley.

The Parks Committee (Mr. J. Burn, Abbey Park), lent a fine collection of Pansies and Clematises which added much to the attraction of the Show, also a number of shrubs in pots and small decorative plants. Mr. T. Fielding Johnson of Brookfield, and Mr. J. Wright of Granby Street, each sent some good Ferns and foliage plants.

The following are the awards of the Judges:—Class 1 (twenty-four Fancy Pansies).—First, Mr. Whitehead. Second, Mr. G. East. Class 2 (twelve ditto).—First, Mr. Yeomans. Second, Mr. Jordan. Third, Mr. Dingley. Class 3 (six ditto).—First, Mr. Yeomans. Second, Mr. Jordan. Third, Mr. Dingley. Class 4 (six ditto).—First, Mr. East. Second, Mr. Dingley. Third, Mr. Bowles. Class 5 (twelve Fancy Pansies; open).—First, Mr. W. Sydenham of Tamworth. Second, Messrs. Biddles & Co., Loughborough. Class 6 for the most tastefully arranged centre stand (for a dinner or supper table). First, Mr. Bell. Second and third, Bowles. Class 7 (eighteen Fancy Pansies).—First, Mr. East. Second, Mr. Whitehead. Class 8 (twelve Show Pansies).—First, Mr. Whitehead. Second, Mr. Jordan. Class 9 (twenty-four Fancy Pansies; open to all).—First, Mr. W. Sydenham. Second, Messrs. Biddles & Co. Class 10 (for the premier bloom in the Show).—Mr. Jordan. Class 11 (for best nine bunches of cut flowers).—First, Mr. Bell. Second, Mr. Barry. Third, Mr. Bowles. Class 12 (for best collection of cut flowers, outdoor grown).—First, Mr. Wright. Second, Mr. Bowles. Third, Mr. East. Class 13 (for a collection of Pyrethrums).—First, second, and third, Mr. Bowles.

In classes 5 and 9 Mr. W. Sydenham was first with John Taylor, David Rennie, Arab, Tom Travis, Louis Wierter. A. H. Murray, Tamworth Yellow, Mrs. Winstanley, Mrs. A. Irvine, Arthur Eaton, Mrs. Maxwell, Maggie M. Phail, Agnes Mabel, Mrs. D. Johnstone, Lieutenant M. Isaac, Edith Crossley, Rev. Gresely, Betsy Kelley, Mrs. C. L. Carnegie, Thomas Garrett, May Hind, John Coutts, and Earl of Warwick, and was closely followed in each case by Messrs. Biddles & Co., Loughborough. The premier bloom (amateur) was in Mr. H. Jordan's stand, a fine Tamworth Yellow.

Mr. A. Bell, gardener to S. Bennett, Esq., in class 11 exhibited some good blooms of *Allamanda grandiflora*, *Lælia purpurata*, *Dendrobium Dalhouseanum*, and *Odontoglossum vexillarium*. Mr. G. Barry was second, and Mr. J. Bowles third.

The outdoor flowers were fresh and well staged, the first going to Mr. Wright, whose stand contained some good *Delphiniums* and *Rhododendrons*. Mr. J. Bowles was second.

The table decorations were rather limited, as only Pansies, Fern, and moss were allowed, the first falling to W. Bell with a very tastefully arranged centre stand, and the second to Miss Bowles.

In the unavoidable absence of Mr. Whitehead, the Hon. Sec., Mr. W. Bell, Hon. Sec. *Chrysanthemum Society*, undertook the management.

## LONDON PANSY AND VIOLET SOCIETY.

JUNE 6TH.

THE first Exhibition of this recently formed Society was held at the Drill Hall, in connection with the meeting of the Royal Horticultural Society, on the above date. Notwithstanding the prolonged drought the flowers on the whole were exceedingly good, and the Executive Committee may be congratulated upon their first attempt to popularise the Pansy in the south. This doubtless will be done if the Society continues its work, and holds a series of annual exhibitions such as the one now reported. An expert Scotch grower expressed his opinion that it was the best Pansy show ever held out of Scotland.

### OPEN CLASSES.

Messrs. Dobbie & Co., Rothesay, were awarded the first prize in the class for trade exhibits of Violas and Pansies. This collection, which was a very beautiful one, comprised amongst the Violas *Duchess of Fife*, *Royalty*, *Mrs. Hay*, *Bullion*, *Lucy Ashton*, *Crimson King*, *Tory*, *Peter Barr*, *Dorothy Tennant*, *Archie Grant*, *Favourite*, *Annie King*, *Ariel*, *Countess of Kintore*, *W. Niel*, *Prince of Orange*, *White Duchess*, *Sheila*, *Countess of Hopetoun*, and several fine seedlings. The Pansies were grand, the blooms being very substantial, and the colours varied. Messrs. Wm. Paul & Son, florists, Bridge of Weir, N.B., were accorded the second prize for a very meritorious collection. Prominent amongst the Violas in this exhibit were *Blue Cloud*, *Lady Amory*, *Champion*, *Ada Adair*, *Bullion*, *Columbine*, *Countess of Kintore*, *Lord Eleho*, and *Countess of Hopetoun*. The Pansies staged in this stand were very fine. The third prize went to Mr. Andrew Irvine, Kyles of Bute, N.B., who staged a good selection. Messrs. Dicksons & Co., Waterloo Place, Edinburgh, competed in this class.

Mr. J. Smellie, Busby, N.B., was deservedly awarded the first prize in the class for forty-eight Fancy Pansies in distinct varieties. The stand comprised *David Rennie*, *Mrs. D. Johnstone*, *J. Taylor*, *James Watson*, *Tom Thumb*, *Lord Hamilton*, *Henry Irving*, *J. Coutts*, *May R. S. Cocker*, *C. B. Renshaw*, *Mrs. Train*, *Mrs. William Watson*, *Maggie A. Scott*, *Jeannie Paterson*, *Mrs. R. Niven*, *Seedling*, *James S. Irvine*, *Mrs. F. A. McGill*, *Maggie Watson*, *Robert Jamieson*, *Alex. Niveson*, *George Anderson*, *Archie Buchanan*, *James Simkins*, *Annie Ross*, *Maggie McPhail*, *Mrs. Dallan*, *A. H. Murray*, *Mrs. J. Downie*, *Jeannie P. Tait*, *William Watson*, *Marmion*, *J. Allen*, *James Campbell*, *Miss Abercrombie*, *Agnes Mabel*, *Mrs. C. E. Scarce*, *Mrs. J. Currie*, *Thos. Gardner*, *Helen Christie*, *Mrs. R. Thompson*, *Mrs. G. P. Addie*, *Donald Morrison*, *Alex. Smellie*, *Jno. Bolton*, *Helen McGregor*, *Alex. Smith*, and *William B. Smellie*. Mr. Alex. Bailey, jun., Silksworth Lane, Sunderland, was accorded the second prize for a very creditable exhibit; Mr. Alexander Lister, Rothesay, N.B., being third.

In the class for twenty-four Fancy Pansies, distinct, Mr. J. Smellie was again first. His stand included *D. Rennie*, *Mrs. D. Johnstone*, *Lord Hamilton*, *Mrs. D. Allan*, *Maggie McPhail*, *C. B. Renshaw*, *Wm. Watson*, *Jas. S. Irvine*, *A. H. Murray*, *C. N. Johnstone*, *Mrs. R. Thompson*, *Thos. Gardner*, *Emmeline*, *Mrs. W. Watson*, *Mrs. J. Ritchie*, *Jeannie Tait*, *Mrs. Carnegie*, *Jas. Campbell*, *Mary Lawrence*, *Mrs. R. Niven*, *Miss Paterson*, and some seedlings. Mr. A. Lister was second, and Mr. Matthew Campbell, Blantyre, N.B., third. For twelve distinct varieties of Fancy Pansies Mr. J. Smellie was first with a very fine exhibit, including *Jno. Allen*, *Mrs. Wm. Watson*, *Mrs. D. Johnstone*, *Maggie McPhail*, *Lord Hamilton*, *Jas. Simkins*, *Mrs. R. Thompson*, *D. Rennie*, *Mrs. A. Irvine*, *Mrs. F. A. McGill*, and *Mrs. W. S. Young*; the second and third prizes being awarded to Mr. A. Lister and Mr. A. Bailey, jun., in the order named.

Mr. A. Lister gained the first prize for twelve Fancy Pansies, one variety, staging *Tom Travis* in grand form. Mr. M. Campbell was second with *Lord Hamilton*, and Mr. A. Bailey, jun., third with *David Rennie*. There were five competitors in this class. For twelve unnamed seedlings, Fancy Pansies, Mr. Lister was also awarded first prize for a meritorious exhibit, Mr. Smellie being second, and Mr. Irvine third.

In the class for twelve Show Pansies, distinct, Mr. J. Smellie was first, staging fine examples of *P. C. D. Boswell*, *Mrs. Brown*, *Dr. Inch*, *G. C. Gordon*, *Mrs. J. Hunter*, *Mary Campbell*, *Minnie Irvine*, *Harry Paul*, *J. Barrowman*, and *Miss E. Bolton*. Mr. A. Lister was second, and Mr. M. Campbell third. The special prize offered by Mr. W. Sydenham, Birmingham, for six Pansies in three varieties, was awarded to Mr. J. Smellie with *Tamworth Hero*, *Emmeline*, and *Tamworth Gem*. Mr. Campbell gained the prize for the best Fancy Pansy in the open classes, staging *Lord Hamilton* in magnificent form.

For twenty-four sprays of Violas the first prize was awarded to

Mr. J. Nicholson, Sewardstone. His stand, which was a most charming one, included *Gold Flake*, *Rose of Morn*, *Dawn of Day*, *Peter Barr*, *Skylark*, *The Mearns*, *Countess of Hopetoun*, *Lady Dinah*, *Lord Eleho*, *Doris*, *Tory*, *Lord Polwarth*, *Countess of Kintore*, *Champion*, *Duchess of Fife*, *Daldowie*, *Wm. Niel*, *Lilias*, *Archie Grant*, *Virginalis*, *Wm. Bellamy*, *Clarinda*, and two seedlings; Mr. Bailey being second with a creditable stand. In the class for twelve sprays of Violas, in distinct varieties, Mr. J. Smellie was first, staging *Stanley*, *Wonder*, *York* and *Lancaster*, *Lady Dundonald*, *Dorothy Tennant*, *Mrs. H. Bellamy*, *Lucy Ashton*, *Peter Barr*, *Mrs. Frater*, and seedlings. Mr. A. J. Rowberry, South Woodford, was second, and Mr. Bailey, jun., third. For six sprays of rayless Violas Mr. Geo. McLeod, Chingford, was awarded the first prize for a fine exhibit, which included *Rose Queen*, *Sylvia*, *Blush Queen*, *Violetta*, *Geo. McLeod*, and *Sylvia's Rival*.

### AMATEURS' CLASSES.

Mr. Pether, Walthamstow, was awarded second prize for twenty-four Fancy Pansies. The best blooms were *G. Anderson*, *Constance*, *John Bryce*, *Neil Galliad*, and *A. Buchanan*. Mr. A. McWilton, Leytonstone, was awarded first for twelve Fancy Pansies, one variety, showing good blooms of *Neil Mackay*. Mr. A. J. Rowberry, South Woodford, was placed first for six Fancy Pansies. The best Pansy in this section was a fine bloom of *Tom Travis*, shown by Mr. Rowberry. Mr. H. A. Needs was second in this class, and Mr. Bruce Cook, Chingford was third. Mr. H. A. Needs, Woking, was first with twelve sprays of Violas, Mr. A. J. Rowberry second, and Mr. E. J. Pether third.

Mr. Rowberry won the first special prize offered by Messrs. Dobbie and Co., Rothesay, N.B., for twelve sprays of Violas, Mr. E. J. Pether being second. Mr. Rowberry was again first for six sprays of rayless Violas. The best six sprays of Viola, three varieties, were staged by Mr. Bruce Cook, Chingford.

For twelve Fancy Pansies, distinct, Mr. A. J. Rowberry was first. Amongst the best of his blooms were *Mrs. J. Downie*, *H. C. Hozier*, *Alex. Ollar*, *W. Dean*, *Don Gray*, *Niel Mackay*, and *W. Rennie*. Mr. H. A. Needs, Woking, was second; and Mr. H. W. Hitch third.

Mr. B. Cook was first in the class for six sprays of Violas, distinct, showing a charming collection. Mr. Edward Fuller, Kelvedon, was awarded the second prize for a stand of Violas in six distinct varieties, three blooms of each, his exhibit being a very beautiful one. Mr. A. McWilton, Leytonstone, was second; and Mr. G. H. West, Chingford, third.

Mr. A. Lister showed a grand collection of Show and Fancy Pansies, not for competition. Mr. J. Smellie staged a fine collection, as also did Mr. A. Bailey, jun.

### FRUIT FORCING.

**VINES.—Early Houses.**—When the Grapes are cleared the inside borders should be kept moist, giving a thorough supply of tepid liquid manure to weakly Vines. This will assist to plump the buds and encourage root action, so essential to the preservation of the foliage in health, and tend to activity of the laterals—the best preventive of premature ripening of the foliage. Thorough ventilation will be necessary constantly, but in cold weather it must be moderated, leaving enough to ensure a circulation. Cleanse the foliage of dust and insects, especially red spider, by thorough syringing, and repeat as necessary to keep the old or main leaves healthy. Fresh laterals will be produced under favourable conditions, and an even growth should be maintained all over the Vines, pinching the gross and encouraging the weak, but keep them clear of the principal leaves which nourish the buds at their base. The mulching or covering having been removed from the outside border, and sufficient of the lighter part left to protect the roots, an application of liquid manure may be given, but avoid making the soil sodden.

**Houses Started Early in the Year.**—Vines started at the new year, and being early varieties, now have the fruit ripe, which will keep better and longer in a moderately moist atmosphere than in an arid one, provided it is not close, sufficient ventilation being given to ensure a circulation of air. The floors and borders should be damped occasionally, and the roots must not lack moisture. A double thickness of herring not drawn over the roof will aid *Hampshire Grapes* in retaining their colour. Allow a moderate extension of the laterals, but keep gross growths well under so as to cause an equal distribution of the sap, and maintain a minimum temperature of 60°.

Vines that were started about the new year for the first time, and have been brought forward gently, will have the Grapes well advanced in ripening, and should have a circulation of warm, rather dry air constantly, increasing the ventilation early. Excessive evaporation must be prevented on hot days by damping the floors and borders, allowing the temperature to fall to 65° or 60° on cold nights, with sufficient ventilation and heat in the pipes to prevent moisture condensing, and

maintain a temperature of 70° to 75° by day. If there is likely to be any want of finish allow the Vines time by giving as long a rest at night as possible. Examine the borders, and if there is any lack of moisture give a thorough supply of water in the morning of a fine day, and when soaked in mulch with a little light material.

**Early Muscat Houses.**—Vines of the Muscat of Alexandria started at the new year are now ripening their crops, and require a dry condition of the atmosphere, but extreme aridity causes the foliage to fall a prey to red spider. Being gross feeders do not allow any lack of moisture in the soil, but feed with tepid liquid manure or top-dressings of phosphate, potash, and ammonia or nitrogenic substances. Muscats seem to require more phosphoric acid than Sweetwater Grapes, say five parts superphosphate (bone) and two parts nitrate of potash (saltpetre finely powdered), with a little sulphur, say one part gypsum, mix, and apply at the rate of half a pound per square yard after making the border moist with tepid water, and afterwards wash the top-dressing in moderately. A light mulching of stable manure will supply similar elements, slowly conserve the moisture, and compensate for the drier condition of the atmosphere. Lateral extension at this stage is the best safeguard against shanking, along with a steady temperature and the avoidance of sudden fluctuations and depressions. Maintain a night temperature of 70°, falling 5° through the night, ventilate early, but allow the heat to rise to 80° or 85° with a little sun and more air, and 90° to 95° with sun in full force, regulating the ventilation accordingly. The old leaves of Muscat of Alexandria are more liable to be scorched under sudden atmospheric changes than any other variety, especially after a dull, cold period. In very bright weather a single thickness of herring net may be drawn over the roof lights, which breaks the sun's rays sufficiently, and the berries will not be scorched or scalded on the upper side, as sometimes occurs in the early stages of ripening. Give a little air at night to prevent the condensation of moisture, and increase early in the day, so that the berries warm equally with the surrounding atmosphere.

**Midseason Houses.**—Grapes that have stoned are swelling rapidly and require abundant supplies of water and nourishment. Native guano is a useful manure for Vines. Blood formed into a paste with wood ashes is also good. There are two ways of making it:—1, Collect the blood in a vessel, add the wood ashes dry and a little at a time, stirring until the whole becomes a stiff mortar-like mass and dry. Use a good handful per square yard when the Vines start into growth, again when the berries are thinned, and a third time when the stoning is completed or the Grapes change colour for ripening. 2, Dry the blood, grind it, and add an equal quantity of wood ashes, applying the mixture as above. The advertised manures, however, save trouble, and are handy, also first-rate for their respective purposes, all being useful for accelerating and sustaining the crops. Some growers prefer a home mixture, which, according to M. Ville, should contain phosphatic, potassic, and nitrogenic elements, but he adds sulphur and lime in sulphate of lime (gypsum). A good mixture may be formed of three parts bone superphosphate, two parts powdered saltpetre, one part ground gypsum, mix and use from quarter to half pound per square yard. These artificials are mainly alluded to because they never impart an unpleasant taste to the Grapes.

The watering, where the borders are well drained, will require to be continued at fortnightly intervals, or oftener where limited, until the Grapes are somewhat advanced in colouring, when it will suffice to keep the soil moist. A little ventilation should be provided constantly at the apex, increasing it early in the day, closing with a genial condition of the atmosphere. Fire heat will only be necessary to secure 60° to 65° at night and 70° to 75° by day, keeping through the day at 80° to 85°, and closing sufficiently early to run up to 90° or 95°. This will insure the berries swelling well, and with a free circulation of air a good finish may be secured. Where the Grapes are stoning a regular temperature of about 65° at night and 5° to 10° more by day will be sufficient, with a further advance of 10° to 15° from sun heat, admitting air early so as to dissipate the moisture before the sun shines powerfully upon the house. Although a moderate lateral extension be essential overcrowding must be avoided, retaining no more foliage than can have full exposure to light. Feed with liquid manure or surface dressings more of a substantial than a stimulating nature, and mulch lightly, especially in light soils, to conserve the moisture and encourage surface roots. With the Grapes just thinned every encouragement should be given to the swelling by early closing and maintaining a moist and high atmosphere. Allow the laterals to extend as far as space admits without crowding, and supply water or liquid manure at the roots liberally, but avoid excessive vigour by applying phosphatic elements as superphosphate.

**Late Houses.**—Except in the latest houses the Grapes will now have been thinned, and where not it should be attended to as soon as the fertilised berries can be seen by their taking the lead in swelling. Syringing may be practised once to cleanse the bunches of the remains of the flowers, otherwise the syringe should not be used over the foliage after the Grapes are set, as most water, even soft and clear rain, leave a stain which becomes conspicuous when the Grapes are ripe. Late Grapes should be thinned more severely than midseason varieties in order to admit air freely into the interior of the bunches, and make it easier to remove decayed berries. Permit the laterals to extend until the available space is fairly covered with foliage, but avoid overcrowding, especially of the principal leaves. Very close pinching may be practised where the crop is proportionate to the foliage, erring, if at all, on the side of a light rather than a heavy crop in such circumstances. Damp

the available surfaces in the house in the morning and afternoon, and an occasional sprinkling with liquid manure will do much to invigorate the Vines and keep red spider in check. Surface-dress inside borders with sweetened horse droppings, little and often, as too much ammonia will injure the foliage.

Give inside borders a thorough soaking of tepid water or liquid manure as may be considered necessary on account of the crops and vigour of the Vines. Outside borders also will require copious supplies of water where the rainfall is inadequate to moisten them through to the drainage, and they may be lightly mulched with short manure. Ventilate early, or between 70° and 75°, and increase with the advancing sun heat; and allow a good rise from that source, closing at 80° to 85°, and rising to 90° or 95°. Leave a little ventilation at the top of the house at night to prevent excessive condensation.

#### THE KITCHEN GARDEN.

**Asparagus.**—Seeing that cutting commenced nearly a month earlier than usual it ought to cease that much sooner, or the plants will become so much exhausted that next season's growth will not be at all satisfactory. Strong crowns or buds are never formed at the base of weakly growths, and unless the rainfall is well up to the average during June Asparagus growths in many cases will be very feeble indeed. In all warm localities Peas should now be plentiful, and that admits of Asparagus being withheld from the dining-table; but in very backward localities there is less need for discontinuing cutting the latter for a few days longer. It is now when a mulching of strawy manure would be of the greatest service to the beds generally, and to those newly planted in particular, always supposing a close look out is kept for slugs. It is in showery weather when the slugs are most to be feared, and if let alone they eat all the bark from the young shoots and even those fairly old. Hand-picking early in the morning is the surest remedy, though occasional dustings of soot and lime will check them considerably. A liberal surfacing of salt in showery weather is most beneficial to Asparagus, and is also destructive of slugs and weeds. It is only at this time of year that it should be applied to clayey soils. Rough winds are very detrimental to Asparagus, and the extra strong tall growths should be supported by means of stakes of some kind.

**Runner Beans.**—Where the soil was properly moistened for the seed the plants have come up quickly, evenly, and strongly, and in many instances ought to be thinned-out rather freely. If there are any blanks to be made good or another row is needed make use of the thinnings for this purpose. Prior to moving them with a trowel give both the rows of plants and the sites to be planted a good soaking of water. When Runner Beans are left as thickly as they come up, or say not more than 3 inches apart, they eventually smother and greatly weaken each other, whereas if early thinned to such distances as will leave one or, at the most, two plants to each stake or pole, that will give much better results. Crowded rows are the first to feel the ill effects of drought, and the first to fail later in the season. Stakes or poles from 20 feet down to 4 feet in length may be placed to these Beans, as they will climb to a great height if liberally treated at the roots. The double rows should, if possible, have two lines of fairly long stakes, these being set out about 15 inches wide at the bottom, and crossing each other a similar distance from the top, and being duly laced together by means of other stakes running along the point of crossing, no winds will greatly disturb them. If stakes from 6 feet to 9 feet in length are used in single lines these also should be braced together near the top, or when heavily laden with haulm and beans strong winds will upset them. Never neglect this staking till the running growths are in a confused mass, as it will be next to impossible to properly uncoil these without damaging them. Those not to be staked must have the running growths kept closely snipped out, the strong flower spikes being then freely pushed out from the few joints about and above the seed leaves. In dry weather give occasional soakings of water and a mulching of strawy manure.

**Kidney Beans.**—These also ought to be freely thinned out, leaving the plants of early or only moderately strong growers about 8 inches asunder, and Canadian Wonder 12 inches apart in the rows. If extra fine straight pods are desired at any time keep the plants staked upright, freely thin out the young pods, water in dry weather, and mulch. These are not much in demand after once Runner Beans are plentiful; but where they are preferred successional sowings should be made every fortnight or three weeks, discontinuing about the first week in August. They succeed admirably through the centres of the spaces between Celery trenches, and are not greatly injured by having the soil narrowed up to the roots accordingly, as it is wanted for surrounding the Celery.

**Cauliflowers.**—The earliest Cauliflowers did not, as a rule, follow immediately the latest Broccoli, but were not very far behind. Caterpillars are very injurious to these crops, and ought to be kept down by hand-picking, or they will quickly spoil many of the hearts. In order to keep the latter thoroughly well blanched the upper leaves should either be tied together, or else some of the lower ones may be broken off and tucked over the heart. It is now when liquid manure, freely applied, will do the most good, this causing the hearts to attain their full size. Driblets are quite wasted on Cauliflowers, and they ought always to have a thorough soaking, once a week being often enough in most cases, especially if solid manure was freely dug into the ground. Every opportunity should be taken of getting out the varieties Eclipse and Autumn Giant, these affording a long succession of extra solid hearts next autumn. On good ground 30 inches apart each way is not too

much space to allow these, but if planted on firm ground manured for preceding crops only 2 feet is enough.

**Celery.**—If wanted extra early the plants ought, ere this, to have been put out; but for ordinary purposes, and to meet the requirements of most places, the early part of June is soon enough to put out the earliest raised plants. In any case they ought to have been pricked out and grown into sturdy plants before being transferred to the beds or trenches, and any delay in transplanting after they touch each other should be avoided. Exhibition Celery is most surely had by planting on the level or even slightly raised beds, the site being well in the open and prepared by a liberal admixture of loam, ashes from a garden smother, and solid manure. They may be planted from 15 inches to 18 asunder each way, and being kept well supplied with water and liquid manure. Celery thus treated grows more rapidly and strongly than it does as a rule in trenches. The blanching can be effected by means of brown paper bandages. For ordinary purposes trenches 18 inches wide with 4 feet spaces between answer well, though trenches another 6 inches wider are frequently made to hold a double row of plants, solid manure being freely forked in in each case. Give the plants a good soaking of water before they are moved, lift with a ball of soil about the roots, and replant 8 inches apart in a single row, or a foot asunder in double rows. After planting give a watering, and keep them constantly moist during the rest of the summer. Sprinkling the foliage in the evenings of bright days is beneficial, and if these few details are observed sturdy plants will not flag in quite the hottest weather.

#### PLANT HOUSES.

**Lilium Harrisii.**—Plants that have flowered may be stood outside and cut down within a foot of their base, when they will start again into growth and produce flowers in the autumn. Later plants must be kept perfectly cool and free from aphides by fumigating or dusting them with tobacco powder. The latest of all will do well in cold frames, where the lights can be thrown off daily in order to keep them back as much as possible in addition to keeping them dwarf.

**Epacris.**—Those that have started well into growth should now have air admitted to them liberally by day, and a little may be left on during the night. If the pots are standing on ashes or other moisture-holding material, shading should be dispensed with. These plants need abundance of light to ripen and harden the wood as it is made. This is essential if they are to bloom profusely another season.

**Erica hyemalis.**—These should be in frames and abundance of air should be given them. If possible raise the frames slightly at the base, so that a good circulation of air can penetrate freely to the lower portion of the plants. Rapid growth can be produced by close confined treatment, but this is unwise if the plants are to flower freely. Sturdy, well-ripened growth is the secret of success. Close confined treatment soon ruins such kinds as *E. autumnalis* and *E. caffra*. The decaying flowers should be removed from the varieties of *E. ventricosa* as they go out of bloom. The base on which all hard-wooded Heaths stand should be kept moist, and too much air cannot well be given them.

**Cytisus.**—Plants that have commenced growth after being cut back may be potted if they need more root room. These plants do well in good loam, sand, and one-seventh of decayed manure. After potting place the plants in a cold frame and give them plenty of air. Any shoots that take the lead should be pinched, so that the plants will form close compact bushes. Nothing is gained by inducing these plants to make rapid soft growth by keeping them close. Acacias of various kinds that flowered early and have started into growth may also be potted and given the same treatment.

**Solanums.**—Be careful that plants which are placed in the pots in which they are to be used for decoration are not allowed to become dry at their roots, or else they will fail to set berries. Plunge the pots if practicable, and give air liberally. Soot water, after they are rooting freely, is also beneficial. If large plants are needed they may be planted out in frames; but a firm base should be provided, so that the plants can be lifted with good balls of soil at potting time.

**Salvias and Eupatoriums.**—Young plants must be pinched from time to time as they need it to induce them to branch freely. These plants may be gradually hardened to cool-frame treatment, ready for eventually planting outside, or they may be grown in pots and stood out when thoroughly hardened. If the latter do not allow them to become root-bound before they receive their final shift.

**Heliotropes.**—Cuttings that are rooted for autumn and winter flowering may be placed into 3-inch pots, and grown in gentle warmth until they are established, when they may be hardened to cool frame treatment, and finally placed into pots 2 inches larger and stood outside. The only attention needed is to pinch the shoots to induce them to branch.

**Zonal Pelargoniums.**—Place all that are ready into their flowering pots, and gradually harden them in cold frames ready for standing outside whenever the weather is sufficiently favourable. All flowers that show should be removed, as well as the points of the shoots, to induce the plants to branch. The soil should be pressed firmly into the pots, good loam being used, with the addition of sand and one-seventh of manure. Ivy-leaved kinds may be given the same treatment, and will then flower profusely during the autumn and winter if well ripened. Plants that are only just rooted may have their points removed and grown for a time under glass before placing them outside, in fact they should be kept under glass until they are ready for the pots in which they are to flower.

## THE BEE-KEEPER.

### APIARIAN NOTES.

JUST when swarming was beginning to be general about the middle of May the weather changed unfavourably, and continued so till the end of the month. Hives that were prepared to swarm did so with the improved weather on June 1st, having in most cases many queens. The queens of one hive mixed with others, and some entered stock hives, unsettling many swarms. The stocks in every instance killed the invading queens, but swarms swarmed again. As the only remedy to prevent them I inserted a strip of zinc queen excluder in the entrance. This, in some cases, kept the queens inside, but the bees flew out, and although the stock hives were removed 30 yards or more away, the bees found them, and to prevent them entering I had to take them within doors until they settled.

#### UNSETTLED SWARMS.

Strange bees, or several queens, give much trouble. They task the bee-keeper more than all other manipulations put together, and annoy and bewilder the beginner completely. It is not easy to advise what to do under the circumstances. Bees are so capricious, and the best thing the bee-keeper can do is to study their many ways of acting, then be prepared to take advantage of it. It would be an easy matter to advise catching the surplus queen, but then there are sometimes from a dozen to a score in one swarm. If we could rely upon the first swarm coming when it is just prepared to do so, before there is a single young queen hatched, the task is easy to depose all the surplus queen cells about a week after the issue of the first swarm. It is no remedy to attempt artificial swarming with a low temperature and amidst rain, because it cannot be performed successfully.

Another difficulty is having several drone-laying bees in a hive. In such cases any attempt of the apiarist to cause the bees to raise queens will be resented by them, or if they do so the queens will be undersized, while it is even more difficult to get the bees in a proper mood to accept a queen. When there are no egg-laying bees present there is no difficulty whatever to introduce an alien queen to any queenless stock, no matter whether the bees be young or old.

#### FEEDING.

During the past fortnight I have been feeding swarms as I recently advised, but sparingly. We usually have to feed till June 20th, but it is probable that we shall finish before that date this year. I would ask inexperienced bee-keepers to think well over the matter before spending money on cumbrous hives. Although I was the first to explain our well tried system it was not enough to warrant me to advise all to rush headlong into the method without experience. Some persons have argued that moderately strong hives gathered more honey than extra strong ones. Only last year one of these writers told us that swarms gathered no honey, or rather if colonies were allowed to swarm there would be an end to honey gathering. I have one hive that has swarmed four times; all are hived and doing well. If it turns out a good season I will let your readers know the result of the hives gathering, and of their increase should any of them swarm again.

#### FOUNDATION.

Although I have manufactured comb foundation for thirty-one years, and at one time advised its use extensively, since I proved the fallacy of 20 lbs. of honey to the 1 lb. of wax theory with the great reduction in the price of sugar, I have modified my views somewhat. Sugar is much cheaper and more satisfactory to use for comb building than much of the comb-foundation in the market. Of course when a laying queen is with the swarm I do not allow time and eggs to be lost, but give all such a proper supply.—A LANARKSHIRE BEE-KEEPER.

H. & E. Albert, 17, Gracechurch Street, London, E.C.—*Application of Artificial Manures.*

F. C. Calvert & Co., Manchester.—*Carbolic Softsoap and Disinfectants.*

Michael Cuthbertson, Public Park Nursery, Rothsay.—*Florists' Flowers and Seeds, and Competitors' Guide.*

Dammann & Co., Naples, Italy.—*Bulbs, Roots, and Orchids.*

## TO CORRESPONDENTS

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Book** (*R. A. P., York*).—We cannot name any particular work as superior to all others. You can best obtain full information by consulting botanical works in a good library, public or private, to which you no doubt have access.

**Pear Tree Shoots** (*J. Hiam*).—Mr. Abbey says there is no trace of mite infection nor the presence of any insects or larvæ on the specimens he has examined. Two of the young shoots, however, have been pierced by some insect about an inch from the base, down to the inner bark, which is more or less discoloured, impeding the flow of the sap, and producing a corticated condition of the bark.

**Wood Ashes** (*E. H. Cottingham*).—We should not hesitate to use the wood ashes or charcoal, the residue of unfortunate conflagrations, in either vegetable quarters or flower borders, even though much salt water was used in subduing the fires; but we should wash the refuse before mixing with soil for plants in pots. Its safety, however, may easily be tested by inserting a few Zonal Pelargonium cuttings in some of it sifted for that purpose; also by planting a few Cabbage or other plants in a mixture, say, of half wood ashes and half soil.

**Strong Fumigation** (*J. E.*).—We should not like to risk a "double strength" volume of smoke in a house containing Melons. You can easily ascertain whether mealy bug can be destroyed as you have been advised, by inserting the stems of infested sprays of Gardenias and Stephanotis in water, and placing them under a handlight or in a box, then treating them to a "double strength" dose of smoke. This is what we should do before incurring risk by a strong general fumigation. The effect on Melons could be ascertained in the same way. Mealy bug is kept in subjection by hundreds of good gardeners by insecticides in solution and syringing with clear water.

**Tomatoes in Greenhouse** (*Reader*).—Endeavour to produce strong, firm, sturdy growths by judicious ventilation and watering, in a light position. If, as ought to be the case, flower trusses are freely produced from the main stems, all other growths may be nipped off as they appear, except the main leaves. The plants may extend as high as there is room for them. When in flower shake the trusses or draw the hand lightly over them at midday for dispersing the pollen for fertilisation. If sufficient flower trusses do not form on the main stems lateral growths may extend where there is room for them, taking off their points above the trusses, but avoid overcrowding. With good plants, well managed, we prefer the single stem method of culture.

**"Malmaison" Carnations Dying** (*C. P.*).—A fungus (*Helminthosporium*) often attacks Carnations virulently, and many plants succumb to the attacks of a maggot. As the examples you sent did not satisfy us that the plants had fallen a prey to either fungus or maggots they were submitted to Mr. Worthington G. Smith, who says the plants have succumbed to a virulent attack of Nematodes, minute worms which eat their way inside the leaves, increasing as they go till they devour the plants. We will ask Mr. Smith to say something more about the eelworm pest which attacks Carnations, and in the meantime you had better burn those which the enemy has spoiled, soil and all, for they cannot possibly be restored to health again.

**Melon Plants for Cold Pits** (*G. G.*).—For a pit 6 feet by 4 feet one plant in the centre of each would be sufficient, but as the season is somewhat advanced it would be desirable to place two plants in each pit, say 3 feet apart, making the soil very firm so as to secure a sturdy fruitful habit. After the plants have been stopped once, this being done at the second rough leaf, and the shoots resulting being reduced to four on each plant by rubbing off others while quite young, stop them 9 inches from the sides of the pit, they being distributed evenly over the surface, and from these side shoots will spring, which will show blossoms at the second or third joint. The fruit blossoms have a swelling immediately below the flower the size of peas or horse beans, but staminate or pollen-bearing flowers have not any conspicuous appendage below. The difference is readily apparent, but these flowers must not be removed until the fruits are set and swelling. It is a good plan, however, to pluck one of them, remove its corolla, and apply the pollen to the

fruit-producing flower when fully expanded. This may be practised on all the flowers with benefit, stopping the shoots one joint beyond the fruit at the same time.

**Leaf-cutter Bee** (*W. G. Drovers*).—The bee in your Rose house which cuts away portions of the leaves and deposits them in a crevice in the sill, returning for more, is the leaf-cutter bee (*Apis* or *Megachile centuncularis*), *h*. You will perceive that the leaves you have sent are well represented in the accompanying engraving (fig. 84). The process which one of these bees employs in cutting the pieces of leaf that compose her nest is worthy of attention. Nothing can be more expeditious. With her strong mandibles she cuts without intermission in a curved line so as to detach a triangular portion. When this hangs by the last fibre, lest its weight should carry her to the ground, she balances her little wings for flight, and the moment it parts from the leaf flies off with it in triumph, the detached portion remaining bent between her legs in a direction perpendicular to her body. The body of the insect is about half an inch long. The female, which is the leaf-cutter, is black, covered with ashy coloured hairs; jaws or mandibles large, terminating in four teeth; antennæ black, rather longer than the head; wings slightly transparent, dark tipped, veins black; legs hairy, spurs dull red, pollen brushes of hind legs golden; abdomen heart-shaped. The male's body thickly covered with yellow hair; antennæ longer than head; jaws two-toothed; dense yellow beard between the antennæ; fore thighs dirty yellow at the outward tip; abdomen rather oval,

FIG. 84.—LEAF-CUTTER BEE.

extremity inflexed, obsoletely toothed. In the figure, *d* represents the larva, with its head and the anterior segments of the body protruded out of the case (*b*), the wider part of which is formed of portions of the leaf upon which the larva is feeding, and which it has not yet actually detached from the leaf: *c* indicates the narrower part of the case formed of portions of other leaves, *a* showing the opposite leaflet almost entirely stripped to its midrib, one portion having been consumed and another portion employed in the construction of the narrower part of the case. The proceedings of this larva in the manufacture of its case are full of interest; it will be observed, for instance, that the instinct of the insect teaches it to arrange the narrow strips of the Rose leaf, of which the case is formed, in a spiral direction, that being the only method in which greater length can be given to the case, in order to keep pace with the increased size of the insect; the spire is kept in its position by means of silken threads, which the larva weaves from its mouth, and by which it attaches the mouth of the case to the leaf when it has finally detached the strip. As the soft skin of the larva requires a covering for a defence, so the insect, on the slightest alarm, withdraws into the mouth of the case, otherwise when it desires to feed it protrudes the front of the body for about a quarter of an inch out of the mouth of the case, and then gnaws the Rose leaf at its ease, the pair of legs at the end of its body enabling it to keep firm footing within. The leaf marked *f* in the drawing shows the mining of the larvæ of the moths.

**Campanulate Foxglove** (*F. G.*).—The terminal campanulate flowers are abnormal, and may be regarded as monstrosities—one of them attractive, the other the reverse. Abnormal floral forms in the

Foxglove and other plants with irregular monopetalous corollas, as in *Linaria vulgaris* var. *Peloria*, are not uncommon. In the Foxglove you have sent, the corolla has become greatly enlarged and split into spreading segments, attractively spotted. A very handsome flower of the same character was illustrated in the *Journal of Horticulture* of August 6th, 1891, page 121. We have seen numbers of such flowers periodically during the last thirty years, but varying somewhat in size, form, and marking. They are floral curiosities, and some of them of a distinctly pleasing character. The precise cause of such changes has not been revealed.

**Thrips on Vines (R. M. R.).**—No greater mistake can be made than to allow these insects to increase till Vines are seriously infested before resorting to repressive measures in earnest. Early attacks are visible enough to watchful eyes, and if the first few leaves affected are sponged with a solution of softsoap and tobacco water a horde of insects may be prevented. Fumigation will destroy thrips and not injure Vines or Grapes if tobacco or the best tobacco paper be used. Campbell's rolls, McDougall's sheets, and Lethorion cones have all been found satisfactory. The smoke must be cool, two or three moderate fumigations on consecutive nights being safer than one dense volume of smoke. The fumigations must be repeated in a week. If the insects reach the berries and footstalks the crop of Grapes will be spoiled. As you only allude to one house we should make a determined effort to sponge every leaf, stem, and stalk. We have known a couple of men set to work at 6 P.M., continue till dark, commence again at 4 A.M., and thus banish the pest and save a house of Grapes from ruin. The men were in earnest, and succeeded in their object as earnest men are apt to do. We have known not only crops of Grapes spoiled but Vines ruined by invasions of thrips that drained them of their juices—evils which might have been prevented by quick perception, prompt action, and stern resolution to conquer the invader.

**Weevils on Pear Shoots and Nut Leaves (J. Hiam).**—The green weevils are *Rhynchites betuleti*, which are very abundant this year on Hazel, but they prefer Hornbeam, and among garden trees Pears and Vines. The females form conical habitations for the larvæ out of one or more leaves rolled together, and caused to wither by their stalks being partly gnawed through; the larvæ are full fed by the time the part has fallen off, when they crawl into the earth and become pupæ, and finally the weevils emerge, generally in the following spring. The best remedy is to capture the weevils by shaking the trees over cloths, promptly collecting the weevils and placing them in a pail smeared inside with gas tar, or containing a mixture of softsoap and petroleum, giving a smart "whip" with a birch switch. The curled up withered leaves should be removed and burned. Syringing or spraying the trees with a petroleum and softsoap mixture, say  $\frac{1}{4}$  lb. softsoap dissolved in a gallon of boiling water, adding a wineglassful of petroleum, and churning with a force pump five minutes; or place in a 2 gallon stone bottle, move up and down or to and fro a similar time, then add 3 gallons of hot water and mix thoroughly, using as a spray or through a fine rose syringe when cool enough (90° to 100°). Spraying with Paris green is also effectual, but it must be used weak over trees with hairy leaves, such as Nuts. Pears will stand a mixture of 1 oz. to 20 gallons of water.

**Gloxinias Failing (J. H. Y.).**—A great deal depends on the provision afforded for growing these plants, and on this point you give no indication. The plant you send has had its growth arrested, and the variety is inferior. There may, as you suggest, have been some error in watering, or the position may not have been suitable. We doubt if this particular plant had been overwatered. If it was transferred from a small pot to a larger there is the possibility of the soil having been rather too dry at the time of shifting, but we cannot be certain about this; in fact, in the absence of any information about the treatment accorded it is as difficult to indicate the precise cause of an evil in plants, as it is for a doctor to determine the seat of disease without knowing anything about his patient. Gloxinias do not thrive on a dry open stage, but require a humid atmosphere till in flower. They like a close damp base and a genial temperature of 60° to 75° when growing, but corms will start into growth in a temperature of 55°. They object to full exposure to hot sun, and frequent syringings are not good for them. They will not make free progress if either too wet or too dry when shifted, nor if insufficiently or excessively watered afterwards. All the plants do not require water at the same time. When the soil is at all pasty to the touch it is wet enough; only when it is sufficiently dry to crumble should water be given, and then it ought to be supplied copiously. Light surface sprinklings are delusive and dangerous, for if the soil is dry towards the bottom of the pots and wet on the top the plants must fail. They should be examined for watering twice a day. The soil must be suitable. We have known serious plant failures this year through too much chemical manure having been mixed with the compost. In a suitable house few plants are more easy to grow than Gloxinias, and not many are more beautiful when the varieties are good and as well grown as Sir William Pink's, described on page 455. You will there find a suitable soil mixture. Mr. Hunt attributes much of his success to the non-removal of the old soil from the corms; but some persons have not succeeded so well as he has when trying that plan, and he would not fail if he abandoned it, though he would be foolish to do so. It is only wise to change methods that do not prove satisfactory, and some persons attain their object in one way, some in another. Another point worth mentioning is this—plants from some strains of Gloxinias are "miffy," and can only be made to grow freely by experts who have the best means at command, while plants from a different strain grow like Cabbages if a fair chance is afforded them.

Again, we have to remember that a fungoid disease attacks many plants, but those of a robust character, through inherent vigour and good culture, are the least likely to be affected. You would perhaps do well to raise a fresh stock from seed if you have the requisite convenience, or purchase good corms in the spring; they are inexpensive.

**Anisanthus splendens (C. F.).**—This is a greenhouse Iridaceous plant from the Cape of Good Hope, and is usually increased by offsets. Sow the seeds in pots, pans, or boxes of soil composed of sand, loam, and peat in equal parts, to be watered well before sowing, and the seed covered its own thickness with fine soil, and then with squares of glass. A shaded position in a frame would be suitable, as the soil would not dry so rapidly as in a sunny house, and it must be kept constantly moist. When the seedlings appear remove the glass and assign them a position where they can have sun and air. When large enough they can be transplanted in other boxes, and eventually be placed singly in pots. A frame is a suitable place for growing them in summer, and they can be wintered in a greenhouse.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*F. H. K.*)—Cape Spurge, *Euphorbia Lathyris*. (*E. S.*)—*Lælia purpurata*. (*T. F.*)—Orchid, *Brassia verrucosa*, poor form; yellow flower, *Acacia cultriformis*; basket plant, *Saxifraga sarmentosa*; Fern, *Asplenium lucidum*. (*A. R.*)—1 and 2, Forms of *Saxifraga MacNabiana*; 3, *S. melliana*; 4, *S. hypnoides* var.; 5, Specimen insufficient; 6, *S. cuneifolia*. (*J. L.*)—*Eriophorum polystachyum* (Cotton Grass). (*J. W. L.*)—*Bignonia lactiflora*. (*W. H.*)—We do not know a plant "commonly called Rose Noble." Possibly some of our readers may be able to give you its botanical name.

### A SPRING DROUGHT.

CONFLICTING reports as to the influence of the long spring drought are so numerous, that it is worth while inquiring if it has done material harm or good, and why its influence has been beneficial or otherwise, in order that its lessons may be turned to account in the improvement in practice which is the aim and effort of every sensible farmer. Our opportunities for observation in southern and midland counties have brought conviction that as usual it is in badly cultivated land that the crops have suffered from drought, and it is the men of luck and chance, taking whatever the seasons may bring them, without an effort at improvement, who complain, and who undoubtedly suffer. Of this there can be no doubt: it is on heavy wet land that corn is coming into ear on very short straw; it is also on poor pasture that the hay crop is a failure. Everywhere in the corn-growing district it is evident that on rich well-cultivated land the Wheat looks well enough. Wheat land for Wheat, and that of the best, is the lesson plainly taught; it is enforced by the thin yellow growth, with small ears, of the Wheat on light poor soil.

In some districts the drought appears to have proved a positive blessing; as, for example, in the arable districts of north-eastern England it is regarded as having been a spring of almost unmixed advantage. In Scotland, according to the "North British Agriculturist," "Scottish farmers are all agreed in declaring that never, in the recollection of the present generation, has a better or more favourable spring been experienced." A full average crop of hay, it is added, is now expected, food for stock is very abundant, and a large breadth of Turnips has been sown under the most favourable conditions. Turning to the north-west of England, farmers are now certain of an average crop of seeds and hay; with another fortnight of warm showery weather such crops will be much above the average. There, as in Derbyshire, the pasture has never lost colour; in Derbyshire growth has in some parts been so short that stock have been turned into some of the grass reserved for mowing; but in Lancashire it has never gone off, and "seeds" have been in cut a month earlier than usual. In Surrey we have in some parts seen excellent crops, while in others it is thought there can be no hay, and there are complaints of corn coming prematurely into ear. It is very much the same in Kent, where some of the small farmers, already behindhand with the rent, and without means to bring the soil at all up to a fair standard of fertility, are now struggling for bare subsistence, with no prospect of a hay crop, and a certainty of inferior corn crops. Those of them having fruit or Hops may do well, but for those entirely dependent upon ordinary farm crops the difficulties may well appear insuperable.

To such men the lesson of the drought assuredly is, Cease to follow the practice of the large farmers; cultivate only enough land for corn for home use; have a fair proportion of Hops, fruit, and such sorts of vegetables as are calculated to afford some profit. Do not forget that of fruit Strawberries come into bearing a year after planting, bush fruits the second year, increasing in produce for several years subsequently; Apples of such sorts as Stirling Castle, Lord Grosvenor, Duchess of Oldenburg, and Keswick Codlin almost as soon, and that a mixed plantation of the best fruit is one of the most profitable crops on a small farm under really good management. Poultry, milk, butter, cheese, are also produce worthy of the small farmers' special attention; there is money in all of them. If the profits

are small the returns are quick, and capital may be turned over many times in the year, the amount of profit resting very much upon management and skill. For example, the man whose cows have now a full feed of grass finds the milk yield improve both in quantity and quality, while he who has to eke out the grass with hay and oil cake complains of a serious falling off in milk yield and in butter. Nor is the butter really good, cake has been used so generally for dairy cows this spring that the butter has been decidedly inferior. Even now it ranges in price from 8d. or 10d. up to twice that amount per pound. Plenty of butter at the lower prices is to be had at Newark Market every week—not this season only, but every season. Surely South Lincolnshire farmers could do better than this. The common fault appears to be bad management in dairy and cowhouse, the result being an inferior article. Would not the makers of such butter be surprised to hear that much of it is passed through the butter worker, well washed, made up in more tempting form, and re-sold at a profit? Yet such is the case.

### WORK ON THE HOME FARM.

Seed germination in some fields of spring corn has been so irregular that much of it did not show plant till the drought broke. This points to a little difference in the time of ripening, which must not be forgotten as harvest approaches. There has also been a second drilling of Turnips in fields where the soil dried quickly into a hard crust after the first sowing. With frequent showers, and soil so warm, second sowings were entirely worth while, and with plenty of manure in the soil the young plant is certain to grow quickly out of harm's way. According to the results of sixty-one experiments, carried out by the Highland Society last year in different parts of Scotland with manure for Swedes, the greatest yield of 17 tons 9 cwt. of roots was obtained at a cost of 26s. per acre for  $4\frac{1}{2}$  cwt. of basic slag, 3 cwt. superphosphate, and 1 cwt. nitrate of soda. It is also noteworthy that in these trials a mixture of slag and superphosphate has proved superior to either of these phosphatic manures alone; and that the same mixture of phosphates without any nitrate, costing only 17s. per acre, gave an average yield of 16 tons 1 cwt., or only 1 ton 8 cwt. less than where the nitrate was added at an additional cost of 9s.

Transplant Emperor Cabbage now to come into use in October, just when the herbage of pasture is becoming thin and innutritious, and to follow it transplant any of the larger sorts of Drumhead Cabbage. No crop repays us better for generous treatment than this, our aim being to obtain large firm hearts as being decidedly more nutritious than the outer leaves. Thousand-headed Kale intended for use in the autumn should also be transplanted soon, and for a winter and spring supply follow with other crops transplanted in July. Particular attention is advisable to these and other green crops calculated to afford a supply of cattle food for next autumn and winter.

TRADE EXHIBITS AT AGRICULTURAL SHOWS.—Messrs. Edward Webb & Sons, Wordsley, desire us to state that they had a large and diversified exhibit of their specialties at the Bath and West of England Show at Gloucester; and Messrs. James Carter & Co., High Holborn, wish us to announce that they have a fine display of pasture Grasses and Clovers at the Royal Agricultural Society's Show at Chester.

### REMARKS.

23th.—Generally sunny till about 1 P.M., overcast and threatening after.  
 29th.—Brilliant early, and generally sunny in the morning; overcast afternoon with spots of rain at 3 P.M., and rain with thunder from 4 to 5 P.M., and showers later.  
 30th.—Rain from 1 to 5 A.M.; overcast all day; gleams of sun at sunset.  
 31st.—Overcast early, but generally sunny after 10 A.M.  
 1st.—Bright early; dull day, with occasional sun.  
 2nd.—Generally cloudy in morning; occasional sunshine in afternoon; fine evening.  
 3rd.—Bright early; overcast morning up to 10.30, then bright rest of day.  
 The first week since January in which the temperature has been below the average, and even this is but very slightly so.—G. J. SYMONS.

I HAVE long been a reader of the *Journal of Horticulture*, and being greatly interested in Tomatoes, I always read everything I see in any way connected with their culture, but I have not seen any mention made in your columns of a disease—if disease it is—that is very prevalent among Tomatoes in this locality. Before coming to this place, nineteen months ago, I never saw a plant affected by it, but during last summer and again within the past two months I have lost several plants, and seen probably hundreds in different gardens, besides hearing of others in various places I have not visited.

The plants die suddenly, sometimes entirely collapsing in a few hours, at other times it is several days after the lower leaves droop before the plants die. I grow them in pots, and planted out in a house facing east, another west, another nearly north, and a span-roofed house facing east and west, where they get the sun from its rise to its setting, and in every house, in pots and planted out, I have lost a few plants. One friend has told me it is caused by too much water, while another says they have not had enough. But against this I should say I have tried to kill certain plants by watering considerably oftener than required, and others I have kept dry, letting them go without water for days together, but could not succeed in killing one by either method.

I have had seed each year from a man who has never been troubled with the plants dying thus. They die in all stages of their growth, from small plants a foot high (rarely before they attain that height) to plants 6 to 8 feet high, with a full crop of fruit.

I hope my letter will be the means of bringing forward some interesting communications respecting Tomatoes and the diseases of which their stems, leaves, roots, and fruits are susceptible.—CHARLES LOCK, *Bristol*.

I SEND a Tomato plant, and the roots of another. Several amongst my crop have gone off in the same way. The leaves flag and then wither, some plants die entirely, others shoot out again round the bottom. I send also several blooms which have dried and fallen from other plants in good health. The Tomatoes are grown in houses heated to about 60° at night, higher in the day, always a little air at night, and plenty during the day. Occasionally on extra cold nights the thermometer has fallen to 55° and even 50°. An answer in the *Journal of Horticulture* will oblige.—X. Y. Z.

[As Mr. G. Abbey is devoting special attention to diseases of plants that are more or less obscure in their origin and action, we sent him the specimens referred to for a searching microscopic examination. The following is his report thereon:—

“The specimens have been carefully examined. They are not infested with fungi nor attacked by eelworms, but swarm with bacteria. The root-part of one plant was completely dead, every portion of the stem and the root tissues being entirely decayed and taken possession of by fungi, which generally accompany decay, and are only found on dead—never on living—vegetable matter. The other plant was alive—that is, its tissues were full of sap except the root portion, this being more or less dried, and the whole thoroughly infested with the spores of a bacterium hitherto unnamed, but which as it was first discovered by the eminent American

scientist, Dr. Byron Halsted (*‘Bacteria of the Melons,’ Botanical Gazette*, November, 1891), I shall refer to as B. Halstedii. We may say that the disease is equally fatal to Gourds, Squashes, Vegetable Marrows, also Cucumbers or Melons, and it is the same that attacks Tomatoes. The attack is marked by a decay of the stem in proximity to the root, and then the whole plant collapses suddenly—sometimes in a few hours. This, however, is not always the case, for occasionally one or more leaves will turn a sickly yellow and the plants die slowly. In many cases the fruit does not exhibit more signs of disease than a few yellowish specks.

“The root portion of the plant examined consisted of tissues teeming with bacteria, the whole being destroyed and incapable of transmitting sap, consequently the leaves fell, and the stem would of course fail in due time. A transverse section through the stem on the seemingly live part revealed a discoloured band immediately below the bark, entirely extending around the inner woody portion and pith, and the watery tissue contained a multitudinous host of bacteria. Making a transverse section through the petiole of the leaf, innumerable bacteria were found. Then a transverse section of the fruit disclosed one side discoloured, and the other proved to be so under the microscope, but there was a difference: 1, The discoloured side contained only one kind of bacteria—the same malignant form as found in the stem and petiole of the leaf; 2, the side of a normal colour teemed with bacteria of a globular form, and there was not 10 per cent. of the other form, which is roundish oval, interspersed.

“A drop of juice taken from the stem contained spores much smaller than the active bacterial form in countless numbers. Another drop from the petiole of the leaf also teemed with bacteria, and a drop of juice from the discoloured portion of the fruit swarmed with the animalculæ of the malignant order, and about 3 per cent. of the globular. One of the latter forms had become oval; attached to its outer surface were some small oval bodies, and they manifestly were eating it. A drop of juice from the seemingly half-and-half mixture of fluids between the discoloured and normal portion of the fruit contained about an equal proportion of the perfectly round and the much smaller oval bodies, but the globular bodies were far more minute than in juice from healthy tissues; yet one of the full-sized globular bodies had within its central orifice four full-sized and three half-grown oval-shaped bodies, and they were already causing the globular body to assume a pointed oval form. A drop of juice also from the apparently healthy portion of the fruit contained at least 87 per cent. of the globular bodies, and the 13 per cent. of oval bodies interspersed with them were much smaller than those in the diseased tissues, and so far as we could determine inert.

“Now, the perfectly globular bodies with a transparent centre or hole through them are found in all pure water, more abundantly in winter than in summer, from wells and springs, they being scarce in summer in those waters, and are never found in impure water, dirty pools, and polluted streams. They increase from the centre, throw out a bud, and a perfect globular body launches forth in less than twenty minutes on its errand of health to man and beast and plants, for they love pure water—that of the clouds. Any kind of water will not do for plants, and it is possible that the malignant bacterial spores may be introduced with impure water, especially liquid manure.

“The other body—*Bacterium Halstedii*—also increases by division, it is said in the centre; but the roundish oval bodies certainly bud from the blunt end of the oval, sometimes pushing two buds from near the crown, and not unfrequently from the small end. This goes on indefinitely, and the bodies occasionally lie in heaps and appear concatenate; but they easily separate on the introduction of a thinner fluid such as water, or upon sap passing through diseased and carrying them with the flow into healthy tissues. The foregoing is what the specimens revealed, and the results are

given at length, so that any careful examiner may verify the statements by the aid of the microscope.

"The disease, the micro-organism, has not attached itself to the seed. This takes place later, when the whole of the fruit becomes a decayed mass, the firm skin still holding the watery interior in shape, and then it is that the spores or germs of the microbe become attached to the fruit, and may be so transmitted to any part of the world. Perhaps this Bacterial disease has been introduced from America, for it is comparatively new, and certainly of Western rather than Eastern origin.

"That the Bacterium Halstedii is the cause of the disease can easily be determined by taking some of the liquid from a diseased plant and introducing it just beneath the skin of a perfectly healthy plant. If on a fruit the virus may run through it in three or four hours, if on a soft part of the bine or stem in three or four days, and if on the stem near the root it may take several days to destroy the plant. The inoculation is certain to produce the disease on hard parts without a swelling, in softer parts it may produce an hyperthropy, and it never fails to rapidly produce a decay which causes the leaves to "wilt," the stem to shrink, and the fruit to become a watery mass. There is no remedy so far as is at present known, and the only preventive process known is to pull up the plants and burn them, clear out the old soil and replant in fresh, never saving seed from infested plants, and avoiding vegetable matter and animal manures."

We think our readers will agree that the above report, embodying investigations by a practical gardener, may be considered somewhat remarkable. Mr. Abbey has previously afforded evidence of his talent for microscopical work, and his capacity for taking pains in the representation of and discovery in connection with the Hazel bud mite (page 321, April 20th), and in the present issue (page 481) it will be conceded that the orange fungus attacking Roses is ably portrayed and treated. In recognition of our correspondent's aptitude in investigation, and at the same time having in view the importance of the subject of the comparatively new Tomato disease, as well as of drawing the attention of men of science as well as practical cultivators to it, we give the subject prominence in these columns.]

## MARKET PRICES AND PRODUCE.

HAVING in view a good deal of correspondence which we have received from time to time on this subject, we desire to direct attention to the communication of a "Market Grower" on page 451, last week, as we think it contains some wholesome truths that may well be kept in mind both by owners, growers, and packers of fruit; while the discoverers of errors in current price lists may do worse than ponder over some of the remarks of our experienced contributor. Persons who are new to the business of growing produce for market have much to learn, whether they are amateurs or gardeners, and much they do learn if they persevere as our correspondent has done; and we are glad to know that he has turned his knowledge to good account. He has grown old enough to be convinced that persons who live in the market, and whose lives are spent in watching fluctuations in supplies and values, are more capable of representing quotations than are persons miles away, and who arrive at conclusions on wholly different grounds. Prices shift from day to day, and sometimes there is great variation in an hour. We have known Tomatoes priced at 1s. 6d. a pound, which has been challenged as a shilling too low because some were sold at 2s. 6d. a pound, while during the same week costermongers' barrows were piled with fruit selling at 3d. a pound through the arrival of a cargo from a southern clime. Inexperienced outsiders will never become famous in challenging the accuracy of published lists of market prices, especially when these represent actualities on a certain day, and which denote as well as the business transactions of one day can do the state of the market during the week.

The practice of copying prices of fruit from choice samples in fruiterers' shops by ladies and gentlemen, and concluding therefrom that the surplus produce sent from their own gardens for sale should realise anything like equal amounts, is based on the assumption that their own "garden stuff" not wanted at home is

equal to the best picked samples from the entire kingdom, and outside it—a fact which has only to be mentioned to show the absurdity of the proposition. A much truer and fairer method of appraisement is in taking the general average of the market returns. It is a fact also that not one private gardener in a hundred has anything approaching equal conveniences with those market gardeners who make special provision for special crops, and concentrate attention on them.

Our correspondent has also found out the truth about salesmen. That there are sharpers about in connection with all vocations or no vocations is true; but it would be as fair to say that all gardeners are rogues because of the rare occurrence of one being found in jail as to suppose that fruit, flower, and vegetable brokers are swindlers because perhaps once in a generation a salesman may be turned out of Covent Garden for low catch-penny conduct. The recognised business men who are established in this and other markets deal as fairly and honourably with their clients as do any other body of men in London, or they would not be where they are or what they are to-day. They are a most useful body—agents in the distribution of produce that growers themselves cannot convey from door to door and shop to shop; and those growers who cannot attend markets, and who send the most and the best goods to salesmen for disposal on commission, are just those growers who make the most money for themselves, and these do not grumble at agents' methods or market customs.

The remarks of our correspondent on grading and packing fruit are significant. It is home negligence in these matters broadly speaking, that gave growers in other lands the opportunity to establish themselves so firmly in our markets, and though it is humiliating to say it, the truth must come out—namely, foreign fruit in the bulk is preferred to our own—American Apples for instance, both brokers and purchasers having more faith in large consignments in barrels than in home-orchard produce in hampers. Nine fruit-selling grocers out of ten prefer barrels to hampers, and American to English Apples, save and except when the latter are well grown, graded, and packed by men who have good names in the market. It is much the same with other fruits. Mr. Webber of Covent Garden has more than once remarked that there is no lack of able men to grow first-class fruit, but after all their care and labour they spoil it in the packing. It is pitiable to see the deplorable condition in which so much arrives for sale. Then the vendors are surprised that it "fetches nothing." They would, perhaps, be not less surprised if they could see their own fruit when unpacked, and they certainly would "not know it" except by the baskets and labels.

The last words of advice by "Market Grower" ought to be deeply impressed on the minds of all who are engaged in contributing to the fruit, flower, and vegetable supply. Those who are the first in the market with the best of produce need never fear a good sale; but inferior "stuff" during periods of "glut" is better anywhere than in Covent Garden, and sending small, fitful consignments of ordinary produce there is not likely to be very remunerative.

## PRACTICAL HINTS ON MELON CULTURE.

(Concluded from page 430.)

Few things are more annoying to the gardener than to find an apparently healthy Melon plant, carrying a good crop of well-developed fruits, suddenly begin to flag, and in the course of a couple of days collapse altogether. Every effort should be made to prevent such occurrence by fighting diseases or insects in their early stages, and in nine cases out of ten serious damage may be obviated.

Canker is undoubtedly the most troublesome disease with which Melons are affected, and if remedial measures are not promptly employed the plants quickly succumb. This vexatious disease assumes various forms, and is brought about chiefly by too much atmospheric moisture, in conjunction with faulty ventilation and an excess of moisture at the roots. Canker at the collar is the most to be dreaded because it is frequently not discovered till too late for remedies to be effectively applied. Plants attacked at this point, if cut asunder at the junction between root and stem, will generally be found soft and discoloured for about half an inch above and below the cut, while every other part of the roots and stem may be quite healthy. This clearly proves that the conditions which engender disease were present only at that point, or else that the stem is more susceptible to it at the collar. The latter conjecture is, I think, the correct one. Assuming that it is so, this shows the soundness of the practice of keeping the soil dry around the collar of the plants. Even when this has been done I have known plants canker badly at that point. This I believe to be caused by closing too late, using moisture freely at the same time, and providing little or no fire heat at night. No matter how

hot the weather may be, the house or pit ought to be closed early enough to allow the moisture to become evaporated, and a little fire heat at night is beneficial. The top ventilators can then be left open a very little throughout the night, which creates a buoyant atmosphere, and favours the production of short-jointed growths and rich leathery leaves.

Another frequent cause of canker is the lodgement of moisture upon freshly made wounds. Should the main stem become bruised in any way the outer tissues decay, and the natural protection of the softer portions of the stem are thus destroyed, condensed moisture, or that applied with a syringe, sooner or later reaches the bruised parts, and quickly makes short work of the plants unless remedies are applied. Wounds made by the removal of superfluous leaves or shoots often bring about the same results. This is especially the case when these wounds are shaded by other parts of the plant. I have frequently noticed that canker seldom attacks a shoot which has throughout been well exposed to light and air, as the wounds made in thinning or stopping the shoots heal quickly; such growths are firm and wiry.

The best way to prevent canker is to secure short-jointed healthy growths by training them thinly, and maintaining the proper temperature, moisture, and ventilation, according to directions given in previous issues. Keep some newly slaked lime and soot in equal proportions always in readiness, and when shoots are stopped or leaves removed place a little of the mixture upon the wound made. Continue the application until the wound is dried, and pursue the same course when necessary. When traces of canker are discovered shade the plants. If the affected part is near the collar scrape it carefully with a sharp knife, and dress with a mixture of equal parts newly slaked lime and powdered charcoal. Rub this into every particle of the diseased stem, then heap some of the sound materials around it, and repeat the operation twice daily until the tissues are thoroughly dry. Sometimes a stem will split right through and begin to canker on either side; but there is no occasion for despair even then, for by carrying out the above instructions the wounds will generally heal sufficiently to enable the fruits to be brought to maturity. Ventilation and fire heat should be gradually increased, and atmospheric moisture lessened when canker is perceived, water at the roots being also sparingly applied.

Gumming sometimes gives considerable trouble, but this disease is not nearly so common as canker. It is generally caused by growing the plants too strongly, giving too little heat, and too much moisture at the roots. Lessening the supply of water and airing more freely, yet judiciously, will usually arrest its progress. Plants grown on a manure bed or in a pit are the most subject to gumming.

Red spider frequently proves troublesome. With good culture, however, this pest may easily be kept under till the fruits begin to ripen; there is then scarcely time for much harm to be done. The best preventive is syringing two or three times weekly with clarified soot water. If these insects gain a footing every leaf affected should be carefully sponged with a weak solution of soft-soap and water. The hot-water pipes may also be painted with sulphur, but this should only be done in the case of a severe attack. Some cultivators recommend syringing with soapy water, in which a little sulphur has been mixed; this I have tried, but found the leaves were badly disfigured if the solution was used at a sufficient strength to kill the red spider.

Green and black fly may easily be kept under by fumigating on two successive evenings with McDougall's tobacco sheets when these insects are visible. Lethorion cones answer the purpose equally well.

Almost every cultivator has an especial liking for some particular variety. To my mind there is no better Melon grown than Hero of Lockinge. Suttons' Imperial Green and Windsor Castle are also excellent representatives of the green and white-flesh kinds. Blenheim Orange, Suttons' A1, and Hero of Bath are a trio of splendid scarlet-flesh varieties. For growing in pits I know of none better than Golden Perfection, Hero of Lockinge, and Victory of Bristol.—LABOR OMNIA VINCIT.

LÆLIA HYBRIDA MAYNARDI.

At the last meeting of the Royal Horticultural Society a silver-gilt medal was awarded for the best seedling Orchid not exhibited

previous to January, 1893. This, as announced in our last issue, was won by Messrs. F. Sander & Co., St. Albans, who staged a beautiful bigeneric hybrid named *Lælia hybrida* Maynardi. This is the result of a cross between *Lælia pumila* Dayana and *Cattleya dolosa*, the former being the seed parent. A specimen of this hybrid was shown at a previous meeting in February, when the Orchid Committee adjudged an award of merit for it. The flowers

FIG. 85.—LÆLIA HYBRIDA MAYNARDI.

are very attractive. The sepals and petals are rosy purple with darker veins, and the lip is a dark purplish crimson. Fig. 85 represents the flower of this charming hybrid.

#### ANGULOAS.

THESE plants, when well grown, are very striking in appearance, and the structure of the flowers is remarkable. The different species do not vary much in shape, being like Tulips. The lip is balanced on a kind of hinge, which rocks to and fro when the flower is moved, hence the English name "Cradle Orchids."

All the Anguloas require cool treatment, with plenty of water while growing; but after the leaves have fallen they must be kept drier, but not sufficiently so to cause them to shrivel. They should be repotted in early spring in peat moss and a little fibry loam; the pots must be well drained, and the plants kept well up. *A. Clowesi* has large yellow flowers. *A. eburnea* and *A. uniflora* are white, the latter sometimes spotted with brown. *A. Ruckeri* has purple spots on a yellow ground, the variety *sanguinea* being blood red inside, reverse yellow, and is very beautiful.

#### ONCIDIUM CONCOLOR.

This is a charming little species, and one of the most attractive of cool house Orchids. The pseudo-bulbs are about 1½ inch high, furrowed, and bearing two leaves about 7 or 8 inches long. The graceful pendant racemes appear in early spring, and are each about a foot in length. The flowers are bright yellow and last a long time in perfection.

#### ONCIDIUM FLEXUOSUM.

This is, to a certain extent, a neglected Orchid, not in the number of plants that are grown, but in the treatment they frequently receive. Many growers keep it in the cool house, and here it grows fairly well, but it will do much better in an intermediate temperature provided there is a good circulation of air and plenty of atmospheric moisture. Here the plants seem to thoroughly enjoy life, the large bulbs and vigorous flower spikes being ample evidence of this.

Plenty of sphagnum moss should be used in the compost for this Orchid, and it must be kept growing to form a green cushion under the new pseudo-bulbs, the young white roots revelling in the moist moss.

The uses of this Orchid are many and varied. Small, well flowered plants are excellent for grouping, the spikes when cut are serviceable for the tops of epergnes, smaller pieces "making up"

well for buttonholes and sprays. It is also frequently used at shows in the classes for stove and greenhouse cut flowers, the feathery spikes giving lightness to the stands and contrasting well with the bright Anthuriums which often accompany them. In short, there is hardly any arrangement of cut flowers or plants that cannot be improved by the addition of this old but very graceful Orchid.—H. R. R.

#### ODONTOGLOSSUM HARRYANUM.

THIS is a very free-flowering, remarkably handsome, and distinct *Odontoglossum*. It was introduced in 1886 from South America, and since then it has found its way into most gardens in which Orchids are grown. If the plant be given a well-drained pot and a compost of sound fibrous peat, chopped sphagnum moss, and crock dust as a rooting medium, the temperature of an ordinary plant stove or the cool end of a *Cattleya* house to grow in, and be kept uniformly moist at the roots, it will thrive and flower satisfactorily. The crinkling oblong flowers, consisting of purplish-brown sepals streaked with yellow, with petals white at the base, and having broad irregular bands of purple, and white lip striped with purple, are very showy in appearance, and easily recognisable from any other variety of the large and beautiful family of the *Odontoglossum*.—H. W. W.

#### VENTILATING ORCHIDS.

WILL some of your numerous correspondents kindly advise me as to ventilating the following Orchid houses, the plants in which are not doing well? First, the *Odontoglossum* house is kept heavily shaded on bright days with very little air, the temperature often rising to 75° and 80° on warm days, and 55° to 60° at night. Secondly, the *Cattleya* house, with a thick blind and no air till 8.45 A.M., allowing the temperature to rise to 80° or 85° before ventilating, with much moisture on the floor, stages, and at the roots. The plants make weak growth, and fail to flower well; I say they do not have sufficient air, but am over-ruled. Thirdly, a mixed house of Orchids, with a temperature of 80° before ventilating, day temperature 80° to 85°, and 70° at night, with much moisture about them. The plants go sickly, turn yellow, and finally die. If anyone will give me some hint on airing and general treatment of the above I shall feel greatly obliged.—J. E., *Dorking*.

#### MR. W. BULL'S ORCHID EXHIBITION.

FOR some years past the annual Exhibition of Orchids at Mr. W. Bull's Nursery, King's Road, Chelsea, has been an event of special horticultural interest, and this season the Show is no exception to the rule. The plants are tastefully arranged in a long span-roofed house, and make a charming display. The centre and side stages are filled with Orchids in bloom interspersed with Anthuriums, Palms, and other foliage plants. Many of the Orchids possess enough colour to make a rich and varied display, but the brilliancy of the Anthurium spathes adds considerably to the Exhibition, which is well worth a visit. Some of the blooms are perhaps a little past their best, but there is still sufficient to interest even the most fastidious connoisseur in Orchids.

The *Cattleyas* and *Lælias* are the most conspicuous, and of these there are some very fine forms. *Cattleya Mossiæ marginata* is a distinct variety, which shows up prominently amongst the rest. The sepals and petals are a rosy mauve, the lip rich purplish crimson with an orange throat. There is a well defined white margin on the lip, hence apparently its varietal name. Another beautiful form is *C. Mossiæ aurea*. This has bright rosy mauve petals and sepals and a charmingly marked lip. Of no less importance is *Mossiæ majestica*, a most distinct form, with pale rosy sepals and petals, and a bright lip. A very pretty variety of *C. Gaskelliana*, with richly coloured flowers, was noticeable; and the same may be said of *C. Mendelli superba*, which has a grand lip and pure white sepals and petals.

Among the *Lælias*, the various forms of *L. purpurata* are well represented. One of the best of these is *L. purpurata rubella*, which has light rosy mauve sepals and petals and a very richly coloured lip. The beautiful *L. grandis tenebrosa* was also noticeable, there being some splendid flowers of this variety. The bright yellow sprays, of an enormous size, of *Oncidium macranthum* formed a delightful contrast to the more formal blooms of the *Cypripediums*, which are well represented. Amongst others the pretty *C. Stonei* and *C. superciliale* are exceedingly good. *Dendrobiums* also form a feature in the Exhibition, as likewise do the showy *Epidendrum vitellinum majus*, *Saccolabiums*, and *Cymbidium Lowianum eximium*. Of the latter there are some very fine plants. *Lycastes*, *Masdevallias*, and *Angraecums* add interest and variety to the display.

In addition to the large structure referred to there are two other houses filled with *Odontoglossums* and *Miltonias* now in full

bloom. One house devoted to *Miltonia vexillaria* in great variety, the most conspicuous of these being *M. vexillaria rubellum* and a charming form known as *M. v. roseum*. The *Odontoglossums* are also exceedingly good, especially *O. citrosmum* and *O. crispum*, of which there are some superb forms.

#### PACKING PEACHES AND NECTARINES.

MANY and various are the methods of packing Peaches and Nectarines adopted, but if all presumably answer the purpose of those who follow them it cannot be truthfully asserted that there is no room for improvement, in some of them at any rate. As a matter of fact, much valuable fruit is practically spoilt owing to either careless or faulty packing. No fruit is more easily bruised and disfigured than ripe Peaches; and what is also a very important point, no fruit is more quickly tainted in flavour owing to being surrounded or enclosed in either scented boxes or strong-smelling packing material. So susceptible are they of being affected in flavour by contact with scented or musty material that Peaches, and in a lesser degree Nectarines, after being gathered ought never to rest on anything but fresh tissue paper with a padding of some kind underneath. Fruiterers sometimes display them on fresh Vine leaves, but those who know their business take good care to remove the leaves before night arrives. Naturally some varieties are superior in point of quality to others, Royal George, Bellegarde, Crimson Galande, and Grosse Mignonne being among the best, but the majority of other sorts are quite good enough for most people, and if not first-rate in flavour there is all the more reason why every care should be taken to guard against tainting them.

Peaches and Nectarines to travel well ought not to be quite ripe when packed, nor in any case should they be left on the trees till the falling stage is reached. They keep better, travel with least damage, and are really more luscious and richly flavoured when the full ripe state is anticipated by at least one day. Any required for home consumption, or which are to be packed for private use soon after reaching its destination, ought to be gathered directly the fruits are slightly soft at the base. Lightly pressing the under side of a fruit that appears to be ripe enough to test will not injure it, but there must be no finger or thumb marks on the upper surface or the fruit will be very conspicuous, and decay also set in early. For the markets an appearance of ripeness, and in particular plenty of colour, is most needed; slightly under-ripe fruit best meeting the case. Fruit that is inclined to cling to the trees must not be roughly dragged away, or thumb marks will detract considerably from their value; but the gatherer should have a pad of cotton wool in his left hand with which to firmly grasp the fruit, and then, where possible, to cut through the footstalk with a pair of Grape scissors. Nectarine Lord Napier is one of the most difficult to gather without bruising, and the pad and scissors ought certainly to be used for detaching the variety from the trees. If all the trees are examined every morning, and each fruit fit is gathered, there will be no necessity for suspending nets under them. The latter only break the fall, and do not wholly prevent bruising.

Opinions vary both as to the form of box and packing material for Peaches and Nectarines. The fruits vary greatly in size and form, some being extra large both as regards depth and circumference, others being flat and of a good breadth, and still more comparatively small in every way. The boxes, therefore, ought also to vary considerably, it being little short of madness to pack deep fruit in shallow boxes with an insufficiency of packing both above and below to prevent bruising, while very deep boxes are unsuitable for small or flat fruit owing to the unavoidable springiness and eventual shrinkage of the packing material. What market salesmen favour are boxes 24 inches long, 14 inches wide, and 4½ inches deep, these holding twenty-four fairly large Peaches, and rather more Nectarines. These, however, are scarcely deep enough for Sea Eagle, Walburton Admirable, and large fruits of Barrington Peaches, and are larger than are required for fruit from very heavily laden trees. It is advisable to have boxes made for private use in sets, the depths being varied. If there are no opportunities of getting them made very cheaply in the neighbourhood they can be obtained for surprisingly low figures from advertising makers. I find cheap, light boxes from grocers and confectioners answer well for sending by post, being also frequently used when there is no likelihood of the receivers returning the empties. Market salesmen and leading fruiterers now-a-days are always ready to send boxes and baskets suitable for any kind of fruit that is to be consigned to them, and all things considered it is much better to have their boxes than to provide for oneself. Boxes with separate compartments for each fruit are a great mistake.

We have next to consider which is the best kind of packing material out of the several available. Experienced packers largely favour moss for Peaches and Nectarines, and it is extensively used for

the purpose, especially by senders to markets. When abundance of clean springy moss can be raked up from lawns or otherwise collected and dried, well beaten, and thoroughly cleared of rubbish, it answers well, and is the cheapest material that can be had. Unfortunately moss is by no means generally plentiful, at least not such as may be said to be fit for packing soft, easily tainted fruit in. Coarse, earthy-smelling moss will not do, and small quantities of that which is suitable are of little value. Moss must be used freely and not gingerly. First line the boxes with sheets of packing paper, and then place a firm layer of moss not less than 1 inch thick in the bottom. Wrap each fruit in a square of tissue paper, bringing the points of the latter well up together over the nipple of the fruit, and then place in the box and completely surround by moss, enough of the latter being used to well divide the fruit. The base of each fruit ought always to rest on the bed of moss in the bottom of the box, and only the tips of the paper protrude above the same material when finishing off. The lid should press down rather tightly on the paper and moss, the packing being so firmly done as to prevent any movement inside the boxes when these are tested by shaking rather violently. If the packing will not bear this test at the outset, what state will the fruit be in after a certain and inevitable amount of shrinkage accompanied with some rough handling has taken place?

Paper shavings are sometimes recommended as a substitute for moss, but according to my experience they do not answer well, it being a very difficult matter to prevent the fruit shifting in them, and bruising accordingly. Bran is even worse, while the coarser kind of wood wool or shavings is too harsh, too springy, and too strongly scented to be suitable for packing Peaches and Nectarines in. More recently a superior kind of wood wool has been introduced, this being much softer, and if well opened out and cleared of dust a few hours prior to using there is no smell perceptible. This I am now using for Peaches and Nectarines instead of cotton wool as formerly, and as yet there has been no complaint either of the fruit travelling badly or of being tainted in flavour. I have hitherto found Peaches and Nectarines travel better in cotton wool than any other material, always provided each fruit is carefully enclosed in soft paper, and then bound round with folded strips of the wool of sufficient width and in such a manner that the latter shall prevent the fruits touching each other or the box. Cotton wool ought always to be folded skin side outwards, and even then should never come into contact with fruit. When returned it should be dried prior to being used afresh, as it is apt to become moist, also heating slightly, and smelling strongly.

I now use the improved wood wool. The boxes are thickly and firmly padded with it, and after the fruit have been enclosed in squares of tissue paper each has a bandage of wood wool wound round it, all being gradually packed closely and neatly together. The box lids closing down tightly on the points of paper and upper part of bandage, there is no shifting of the fruit afterwards. This plan of bandaging the fruit will be found to answer better than burying them in nests formed in a well-filled box of wood wool, as in the latter case the elasticity of material is apt to gradually reverse the position of the fruit. The fewer nails used in fastening down the better, but the boxes may well be stringed together, and very plainly labelled "Fruit, with care."—MARKET GROWER.

## SOME GOOD ALPINES.

### MORISIA HYPOGÆA.

THIS little plant, which will ere long be eagerly sought after by those who wish to possess the choicest and rarest of the gems of the alpine flora, is not, as is generally imagined, a novelty in this country. It is, however, like many other plants, one which had apparently disappeared from our British gardens, and which has only recently been re-introduced. It was, I understand, figured in the second series of Sweet's "British Flower Garden;" but as I have not access to that work, I am not in a position to state if the figure there given is a faithful representation of the plant. No notice of it appears in Mr. George Nicholson's invaluable "Dictionary of Gardening," but a brief reference appears in "Paxton's Botanical Dictionary," and in the old edition of the "Cottage Gardener's Dictionary." From these and other sources we learn that it was discovered on the Sardinian mountains by Professor Morris, and it is to Cassini that we owe its relegation to a separate genus under the name of *Morisia* in honour of the finder. The specific name *hypogæa* is given on account of its habit of burying its seed pods in the soil. Its original introduction is said to have been due to seeds brought from a botanic garden in Turin in 1833, and it is understood to have been first flowered in this country in 1834. It appears to be quite hardy, and from its disappearance from this country we can only conclude that it had not become widely distributed. For its re-introduction I understand we are

indebted to the recommendations of Mons. H. Correvon of the Jardin Alpin d'Acclimatation, Geneva. The date of its re-introduction appears to be 1890, and it is to be expected that the ease with which it may be propagated will ere long enable it to make its way rapidly to the gardens of the admirers of alpine flowers.

*Morisia hypogæa* forms a dense tuft only an inch or two in height, formed of pretty shining green leaves. These have been described as runcinate, and on turning up the definition of this, which is that "a leaf is said to be runcinate when it is irregularly lobed, the lobes gradually diminishing to the base, and hooked back;" and comparing it with a leaf from one of my plants, one can safely say that the term fairly describes the form of the somewhat thickish leaves. The flowers, produced singly on short stems, are clear and bright yellow, and are nearly the size of a shilling. It is well, however, to state that the one defect of the plant is that the neat and pretty blooms have a tendency to conceal themselves among the foliage instead of standing boldly above it. They appear in April and May. As already said, it seems to be hardy, and judging from the test of the past winter, which was the most severe here for the past nine years, I have little doubt that it will stand the winters we generally experience.

In my garden a small plant was put in gritty sandy peat in a pocket on a rockery facing south-east, and as it was unprotected, in order to test its hardiness, it was satisfactory to see that it survived, although severely "scorched." This plant flowered in due course this spring, but, judging from the character of the foliage, I should be disposed to place a piece of glass over the plant during the winter in such a manner that the air should have free access. A rich gritty soil is a suitable one for this *Morisia*, and judging from the way in which the roots have attached themselves to fragments of shells which were in the soil, it will probably be found to prefer limestone or chalk in the compost. It is readily increased by division or by cuttings; but I have not yet ascertained if it ripens seed in this country.

### LINARIA HEPATICÆFOLIA.

There are several admirable plants among the alpine *Linarias*, and the Hepatica-leaved Toadflax (*Linaria hepaticæfolia*) has a neatness and beauty all its own, which render it well worthy of a place in a collection of rock plants. It is, however, not very frequently met with, and I had some difficulty in obtaining a plant when it was desired some years ago. A figure of *L. hepaticæfolia* appears in Wooster's "Alpine Plants," 2nd series, plate iii. Neither the artist nor the writer of the descriptive notice can, however, be congratulated, as the plate is far from being an admirable representation, and the letterpress is disappointingly meagre.

The Hepatica-leaved Toadflax is a native of Corsica, and forms a dense carpet of creeping foliage scarcely rising above the surface of the soil, and prettily bedecked with its small purple-lilac and white flowers, smaller and less showy than many others of the genus, but still very attractive. The leaves are cordate-reniform, three to five-lobed, and of a pleasing green colour. If grown in a pot or placed at the front of a ledge of the rockery the plant will extend until it hangs gracefully over the rock or pot. *L. hepaticæfolia* is hardy here, and is grown in sandy peat with an admixture of grit on a rockery facing south-west. If planted in suitable soil and receiving an adequate supply of moisture in dry weather in spring it will soon fill a good space, and will give great pleasure to those who see it.

### GYPSOPHILA REPENS.

In walking round my garden to-day the beauty of a plant of the comparatively old *Gypsophila repens* trailing over a slab of fossil limestone so impressed me that I feel it impossible to refrain from calling attention to it. It is now understood to be synonymous with *G. prostrata*, and the variety with which I was so much delighted is the white one, which is forming a cloud of foliage and flower presenting the appearance of beautiful lacework.

The introduction of *G. cerastioides* has placed this species somewhat in the background, but it is hardly possible that it will long remain neglected, and I venture to think that a large plant well displayed would attract much admiration in an exhibit of alpine flowers. *G. repens* is a comparatively old plant in our gardens, having been introduced in the latter part of the last century from Siberia. It is, I believe, also a native of the Alps of Europe. The generic name given by Linnaeus is derived from the Greek words *gypsos*, lime, and *philein*, love, and is expressive of the partiality of the *Gypsophilas* for a calcareous soil.

The species under notice is no exception, and should be grown in a light soil with a supply of chalk or limestone. It is frequently stated to grow about 5 or 6 inches in height, but this, while literally correct, is rather misleading, as the branches extend to a considerable length, one plant here having these 18 inches in length. It will readily be supposed that a plant of this character is seen to

more advantage when trailing over a ledge of rockwork, and its linear, glabrous leaves and its multitude of white or pinkish flowers will form a feature in the garden from May and June to September.

A sunny position is the best for a display of its beauty. It is readily increased by means of seeds. *G. repens* is figured in Maund's "Botanic Garden," vol. i., plate xxx., under the name of *G. prostrata*, but only a small portion of the plant and flower being shown no idea of the habit is given.

#### ANTHEMIS AIZOON.

Distinct in every respect from any of the foregoing, *Anthemis aizoon* is yet worthy of a place in the collection of alpine, possessing as it does the merit of floriferousness, which induced Linnæus to give to the genus the name *Anthemis*, from *anthon*, a flower. It begins to flower in early summer, and continues to bloom for a considerable period. The blooms are rather Daisy-like, but with much broader ray florets, which are white, the disc being also whitish with a tinge of yellow. The leaves are lanceolate and deeply serrated, and they are so covered with down as to present a greyish appearance. *A. aizoon* grows variously from 2 to 5 inches in height, and is extremely neat and compact, even at the latter height, which is almost reached in my garden.

Its requirements appear few, and of its hardiness there seems no doubt, as it stands our winters without protection. I grow it on a rockery facing south-east, where it is placed in a pocket filled with sandy loam. This neat and pretty little plant is a native of northern Greece, and may be increased by means of seeds or cuttings.—S. ARNOTT.

### INSECTS OF THE FLOWER GARDEN.

(Continued from page 413.)

THOSE much disliked and very abundant insects, the spiders, have certainly few friends amongst gardeners, nor is this at all surprising. The mention of their name calls up recollections of shrubs and plants disfigured by their webs, of the frequent transfer of these to the dress while we are occupied in the garden during the season when spiders are most active, and of the occasional travels of the insects themselves amongst the hair or up the sleeves. Spiders there are again, mostly of small size, which annoy the gardener by their habit of entering flowers; sometimes, it would seem, this is to secure a little undisturbed repose; sometimes, too, they lurk in the flowers that they may pounce upon insects visiting them to obtain honey. But, as I have more than once remarked to friends, we have the satisfaction of knowing that our spiders are innocuous. I have never, after much inquiry, been able to find a single instance of a British spider biting any human being, though some of our larger species could probably pierce the skin and inflict a painful wound, if a small one, by injecting poison. Some of the species of hotter countries are known to do so when people are careless about avoiding them or come upon them unawares, and the bite of several species is apt to be very dangerous. Then, again, with regard to our spiders; there is much to be said on their behalf, as busy destroyers of many insects that are troublesome about gardens it is hardly advisable that we should try and expel them altogether from our flower beds could we manage it, though we may not leave all their snares undisturbed. And it has also been asserted that spiders are weather-wise, hence may render us service as natural barometers. It is supposed by their restlessness they may foretell the approach of a storm or gale, which they particularly dislike; and diligence exhibited in web-repairing after a downpour of rain indicates an approach of better weather, if not they hide and remain quiet.

The number of eggs deposited by some of our common garden spiders is large, and a friend who noticed this circumstance asked me how it is the balance is kept even from year to year, for we do not find any great variation in the numbers of these species during different seasons, certainly no marked increase. If the majority of those hatched lived to be adult spiders there would be such an increase; evidently only a part of each brood survives. Some people think young spiders prey upon each other extensively. I rather doubt if this is the case; occurring in companies as they often do, they seem to be amicable together then, though in time they become suspicious of each other. Many juvenile spiders die of the feebleness caused by the changes of skin, which are frequent in their early stage; some are undoubtedly carried off by birds, and some are eaten by other insects, a natural sort of retaliation upon species that are notable insect killers throughout nearly all their lives. Probably the bulk of the spider race are strictly "annuals," but some species are known to be "biennials," passing the winter in crannies and corners, and it is supposed that there are instances of spiders living longer than that, three or even four years. Like

other insects of prey, they can endure a fast of many days, and those that live through the winter eat only now and then. At that season, and also about the end of the autumn, the bags of spider eggs are very observable on walls or palings, and they may easily be crushed if that is thought desirable, but there are good reasons for leaving them alone.

I cannot dwell upon the numerous and curious facts connected with the structure of the spider's web, but only remark, in brief, that the thread or silken cord of which it is formed is composed of a host of extremely fine threads joined together, which issue from the spinnerets at the tail. The ordinary working thread may contain from 2000 to 6000 of these. Another notable fact is that peculiarity of the web which in the usual way enables the insect to move about on it, while the prey is generally entangled. Here and there upon the web a spider places drops of a sort of gummy substance, different from the silk, and by contact with these the fly or other victim is held till the spider can secure it by silken cords ready for eating. But by instinct, while it distributes this gum over a great part of the web the spider leaves certain bridges or gangways over which it can pass freely whenever it needs to do so. Sometimes, most often, it is in the autumn months we find about gardens masses of loose filmy web which has been carried along by the wind, and has served to convey some of the gossamer spiders through the air. It is not the case, however, as used to be thought, that a gossamer spider can start itself on an excursion by throwing out lines of thread to serve as rafts. The fact is that the breeze, in these species, loosens the web from its moorings, and then, on a portion of it, the spider travels to a new locality.

Of all the spiders of the garden, the best known are those of the genus *Epeira*, proprietors of the large geometric webs which are spread over shrubs or herbaceous plants, and have, at times, the spider occupying the centre, at other periods it lurks under a leaf within easy distance. Feminine individuals of the *Epeiras* seem to predominate, hump-backed, round-bodied creatures, frequently having the abdomen beautifully adorned with spots. Their male companions are less in size, slimmer, and appear to be less ravenous. The number of flies that a single *Epeira* captures in a day is considerable during the season when flies are abundant, and the larger species also succeed in ensnaring saw-flies, butterflies, various moths, and even bees occasionally. It is not an uncommon thing for caterpillars to fall into spiders' webs, and many small ones are killed by them; but we notice there are some kinds which spiders evidently dislike, they just taste their juices and then eject them from the web. A peculiarity of the *Epeiras* is, that once at least, in the course of every day, they repair, or reconstruct their nets, even if they do not seem to be damaged. The diadem spider (*E. diademata*) a conspicuous species, is so called, because, to a fanciful eye, the marks upon its body resemble a crown or diadem, but some have likened them to a cross, and French folks style it the "Croix de St. Denis." It is a spider which has a habit of shaking its web, perhaps to test the cords, and, when it has made a capture, frequently twirls the victim rapidly round, and at the same moment it throws threads about the wings or body to prevent escape. As the diadem spiders like their food fresh they do not always kill their prisoners at once. Now and then the webs of this and other garden spiders occur close to the ground, and these usually contain numerous insects that are troublesome to us, such, for instance, as the crane flies or *Tipulæ*, from the subterranean grubs of which we sustain much loss, even in the flower garden. The egg-bag of the *Epeiras* is about half an inch long, and contains a compact mass of 600 or 700 eggs or more. Even yet there are districts in England where people believe that some of the web of garden spiders rolled up and swallowed will relieve ague.—ENTOMOLOGIST.

### STRAWBERRIES.

A NOTE in the Journal of June 8th, that English Strawberries from early localities were then being sold in the streets of London at 4d. per pound was an indication of the near approach of the height of the Strawberry season. Now is the time, therefore, for a comparison of notes of the relative value of sorts in each of the three sections—the earliest, midseason, and late varieties. In doing this, special prominence should be given to varieties which, like Sir Joseph Paxton, are robust, hardy, and free cropping everywhere, because the general cultivation of such varieties insures a full supply of this wholesome fruit. This may be taken as a safe point of departure in Strawberry culture, and it was precisely this idea which induced me to plant a collection, rather than a choice selection, in the experimental fruit plot of the County Council of Derbyshire. At present the collection consists of nine early sorts:—John Ruskin, Noble, Alpha, Black Prince, Keen's Seedling, Early Prolific, Sir Joseph Paxton, Vicomtesse Hericart de Thury, and King of the Earlies.

Thirteen Midseason.—Bicton Pine, Cockscomb, Duc de Malakoff, Lucas, Pioneer, President, Eliza, Sir Charles Napier, The Countess, Phenomena, Carolina Superba, Marshal MacMahon, and British Queen.

Eight Late Sorts.—Waterloo, Enchantress, Frogmore Late Pine, Hélène Gloede, Jubilee, Elton, Souvenir de Kieff, and Bonny Lass.

It was my intention to include in the collection Laxton's Scarlet Queen, and Competitor, Dr. Hogg, James Veitch, La Grosse Sucrée, and Loxford Hall Seedling, but Messrs. T. Rivers & Son, to whom the order was sent, were sold out of all six varieties, which may fairly be taken as an indication of excellence, of which, as regards the last four, I am competent to speak, as I proved them to be worthy of a place long ago. For size, in combination with flavour, Dr. Hogg takes the foremost place among Strawberries, just as the doctor himself does among pomologists. Marguerite is another Strawberry which I much desired to have, but nurserymen appear to have discarded it, as it does not appear in the leading catalogues. For many years it was the most useful early variety I had, and produced enormous crops of magnificent fruit on the Hastings sand in Sussex, about as ungenial a soil in its crude state for fruit culture as has ever fallen to my lot to bring under cultivation. I am aware that Marguerite is regarded as a delicate variety, but considerable experience of it enables me to say that it answers perfectly under good management in rich soil that is well drained and thoroughly porous. It never failed me but once, and then it was owing to my folly in allowing myself to be persuaded to top-dress instead of forking-in manure immediately after the fruiting season. The soil had been trampled hard as the fruit was gathered, it became saturated with water by heavy rain in October, severe frost followed, and the whole of the plants in a large bed perished. There would have been no such loss had I followed my usual practice of making a clearance of rubbish between the rows, and forking in a heavy dressing of farmyard manure, thus breaking up the hard surface of the soil, so that superfluous rain water was certain to pass through it quickly, leaving the soil comparatively dry.

Here is Dr. Hogg's description of Marguerite in the last edition of the "Fruit Manual":—"Fruit very large, conical; skin bright shining red; flesh bright orange, solid, juicy, sugary, and richly flavoured. It is of immense size, and sometimes weighs as much as 3½ ozs." One may well ask, Is this a Strawberry to discard? Certainly somebody finds it worthy of cultivation, for on June 6th I saw several punnets of it at Solomon's in Covent Garden, marked 2s. a punnet, evidently a special price for fruit of exceptional size, by far the finest in the market. I was able to purchase quite double the quantity of smaller fruit of another sort for 6d. If any reader of the *Journal* can put me in the way of obtaining some runners of Marguerite I shall be much obliged.

The Derbyshire Strawberry bed has only been recently planted, so that a comparison of sorts cannot be made till next season. Meanwhile I invite criticism of my list of varieties, with suggestions of desirable additions thereto. A considerable number of sorts planted in a new private garden I have recently laid out in Leicestershire will also come into bearing next season, and I hope to report results from both counties.—EDWARD LUCKHURST.

[On the day this communication reached us (9th inst.) Strawberries were selling in shops and on costermongers' barrows in London for 2d. a lb. Selected fruits in punnets were priced from 4d. to 1s. a lb., according to quality. Records of experience with Strawberries would be interesting and useful.]

## ROYAL HORTICULTURAL SOCIETY.

JUNE 6TH.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters (in the chair), Mr. McLachlan, Dr. Müller, Mr. Wilson, and Rev. G. Henslow, Hon. Sec.

*Clematis*, Double and Single.—Flowers were received of the variety "Proteus," which is remarkable for bearing double flowers on the old wood of the previous year, which are the first to appear, while the present year's wood subsequently bears single blossoms in the autumn.

*Cereus*, Photograph of.—Dr. Masters exhibited a photograph, taken by magnesium light, of a blossom of the Night-flowering *Cereus*, growing at Loughborough.

*Abies balsamea*.—He also showed drawings of this species, exhibiting great variations in the characters of the bracts, scales, colour, &c.

*Cupressus guadeloupensis* and *C. macrocarpa*.—Dr. Masters showed dried specimens of these two forms. The former grows on the island of Guadeloupe, off S. California, and the latter on the mainland on a very limited area. They appear to be only varieties of one another, the island form being more glaucous, a common feature of maritime plants. Dr. Masters also observed that a variety of *Pinus insignis* with two "needles" instead of three, the usual number in this species, together with a Fan Palm, *Erythea edulis*, grew on the same island.

*Calochortus vars.*—Mr. Wilson exhibited blossoms showing great variety of colouring in *C. venustus citrinus* and *C. v. oculatus*. They were grown in open borders at Weybridge and Wisley.

*Aquilegia* and *Clematis Hybrids* (?).—A communication was received from Mr. E. J. Low of Shirenewton, Chepstow, describing some supposed hybrids, accompanied by specimens of *Clematis montana* and a drawing of the "hybrid" *Aquilegia* exhibited at the last meeting. It was the opinion of the Committee that the evidence of its being a true hybrid was not satisfactorily established.

## VIOLAS AND VIOLA CULTURE AND MR. W. DEAN.

THE Rev. David R. Williamson writes to us as follows:—"An exquisite little floral essay on Viola culture has just been published by Messrs. Dobbie & Co., of Rothesay. This gives in condensed form information that is requisite for the culture of the Viola, which, whether as regards its beauty, fragrance, variety of colour, or its marvellous durability is a great acquisition to the modern garden. Among the famous Scottish and English cultivators of the Viola, whose biographies and portraits are given in this instructive and picturesquely written little book are Mr. William Dean, Birmingham; Mr. John Baxter, Daldowie, Perthshire (raiser of the White Duchess and Duchess of Fife); Mr. James Grieve, Edinburgh; Dr. Stuart, Chirnside, Berwickshire; Mr. William Cuthbertson, Rothesay, and Mr. George McLeod of Chingford, the accomplished Secretary of the London Pansy and Violet Society."

[As an old and appreciated contributor to our columns, as a veteran florist than whom none has worked more zealously and disinterestedly in the popularisation of Pansies and Violas, and as the author of the valuable history of the Pansy in Mr. James Simkins' instructive work, "The Pansy," we, by the courtesy of Messrs. Dobbie & Co., insert the portrait of Mr. Dean from their dainty little essay referred to by Mr. Williamson.]

FIG. 86.—MR. WILLIAM DEAN.

## GLOXINIAS AT CHELSEA.

At the Royal Exotic Nursery, Chelsea, is now to be seen at the summit of their beauty a magnificent collection of Gloxinias. Arranged in a low span-roofed house on two flat stages they present a perfect vision of beauty in colours ranging from pure white to a rich deep purple. The compactness and extreme floriferousness of the plants, combined with the charming delicacy of the shades and the wonderful substance of the flowers, create on the mind such an impression as will not quickly pass away. Everyone interested in these plants should see them, and they will be amply repaid for their visit.

What wonderful improvements have been made in the past few years amongst Gloxinias! Now the blooms are short in the tube and broad across the lobes, instead of long and narrow, as they formerly were. The plants at Chelsea are a credit to Messrs. Veitch & Sons, and to their grower, Mr. West. It may be interesting to readers of "our Journal" if a few of the best varieties are named, but all those who have the opportunity of judging for themselves should not fail to grasp it. A worthier variety than Triton, with which I may commence a short selection, cannot be found in any collection. The throat of this flower is light in colour, the lobes, which overlap each other perfectly, being netted with light and dark purple, and having a clearly defined margin of a delightful shade of purple. Cygnet has the throat and lobes pure white margined with purple, which shades at the extreme edges of the flowers to light blue. Monarch is one of the finest. The colour is a rich velvety crimson, and the flower is of the most perfect form. Ruby cannot fail to attract attention, the colour being so soft and pleasing; delicate pink shaded with scarlet can convey but a poor idea of its beauty, for it is one of those flowers which must be seen to be properly appreciated. In Claudia is found still another shade, the ground colour of the lobes being of a unique crimson purple, with a crimson spotted throat and clear blue edges. This variety is remarkably free flowering and of fine habit, each of the flowers having six lobes, and in some seven. Cicely is a bloom having an almost indescribable shade of colouration; dark crimson flushed with purple and having a distinct margin of white will doubtless convey some idea of its beauty. Antigone carries flowers of great substance, the throat and lobes being crimson spotted on a pure white ground, and having a most clearly defined margin of pure white.

Duchess of Connaught has a very light throat, bright scarlet with a pure white margined lobes, and is one of the most striking in the collection. Orestes is of a rich dark velvety crimson colour in the throat and on the lobes, which are edged with a soft pleasing shade of rose. Elvira is one of the most charming. The throat is marbled with red, and the lobes, which are margined with very pale lilac, are purple shaded with bright blue. Sylvia has a white throat, and margins of the lobes are of the purest whiteness surrounding a ground of beautifully soft rose. Sunbeam is undoubtedly one of the most attractive, it having rich scarlet

lobes with a throat of which the ground colour is white but having innumerable bright red spots. Spotted Orion is admirably named; the throat is cream spotted with red and the lobes are white splendidly spotted blue, the broad margin of pure white being very clearly defined. Virginalis is, as its name implies, pure white, and must be counted amongst the best. Claribel is a beautiful flower having pure white throat and lobes, the latter, however, being very slightly spotted red. With Hecla the list must close. It is a pleasing variety, having a white throat densely spotted and feathered, bright red and white margined, velvety red lobes.—H. J. W.

**EVENTS OF THE WEEK.**—The ensuing week will be a busy one amongst horticulturists in the metropolis. On Tuesday, June 20th, the Committees of the Royal Horticultural Society will meet at the Drill Hall, James' Street, S.W., and on that day, and at the same place, the early exhibition of Roses, under the auspices of the National Rose Society, will be held. The annual dinner of the N.R.S. will take place in the evening of the 20th inst. at the Hotel Windsor, Victoria Street, the Very Rev. the Dean of Rochester occupying the chair. A floral fête will be held in the gardens of the Royal Botanic Society, Regent's Park, on Wednesday, June 21st: and on Thursday, June 22nd inst., the annual festival dinner of the Gardeners' Royal Benevolent Institution will take place at the Hôtel Métropole, Baron Schröder presiding.

— **THE WEATHER IN LONDON.**—The weather in the metropolis still continues bright and dry with occasional dull mornings, but no rain. On Sunday and Monday rather cold winds prevailed, but Tuesday was very warm. Wednesday opened similarly, and at the time of going to press the much-needed rain appears to be as far away as ever.

— **WEATHER IN THE NORTH.**—The past two weeks have been warm and fine. No rain has fallen since the 4th inst., when we had some heavy showers. Sunday and Monday were exceptionally warm; the nights, too, have been generally mild with heavy dews.—B. D., *S. Perthshire*.

— **THE DROUGHT IN KENT.**—"J. W. L." writes from Erith:—"Just a few lines to tell you there has now been a drought here for fourteen weeks, and during that time there has only been one hour's rain in all, in paltry showers. Is not that extraordinary? Mangolds are not showing yet, and all fruit trees are very dirty."

— **ROYAL HORTICULTURAL SOCIETY.**—The next meeting of the Society will be held in the Drill Hall, James' Street, Victoria Street, Westminster, on Tuesday, June 20th. Besides the special prizes offered for Pæonies by Messrs. Kelway & Son of Langport, and for lace and border Pinks by Messrs. Turner of Slough, there will also be numerous prizes for competition among members of the National Rose Society. As was announced last week, the National Carnation and Picotee Society's Show, which was to have taken place on July 25th in the Drill Hall, will now be held at Chiswick Gardens on July 11th in conjunction with the Special Show, which has been promoted by the Council of the R.H.S.

— **MR. H. R. WILLIAMS.**—We are pleased to note that Mr. H. R. Williams, who has been twice Master and twice Acting Master of the Fruiterers' Company, has been placed by the Lord Chancellor, on the nomination of the Earl of Strafford, the Lord-Lieutenant, on the Commission of Peace for the County of Middlesex. Mr. Williams is an active supporter of industrial schools, and has taken a leading part in the education of the poor and destitute. In recognition of his service between £300 and £400 were subscribed for presenting him with a service of plate, but this he declined, and requested the investment of the money for a scholarship in the Hornsey Board Schools. Mr. Williams resides at The Priory, Hornsey, taking much interest in his garden and the cultivation of Chrysanthemums. He is a good and just man, and emphatically the right man for the magisterial bench.

— **BEGONIAS AT FOREST HILL.**—These, we are informed, are in exceptionally fine condition in Messrs. Laing & Co.'s establishment. A traveller fresh from a visit to the collection could not resist calling at our office to express his astonishment with what he had seen, and he seemed anxious that editors and reporters, clerks and printers, should have a holiday to see the wonderful flowers that he tried to describe over the counter.

— **NIGHT-BLOOMING CEREUS.**—We had last evening (the 6th inst.) in this garden nine full blooms on one plant of this magnificent Cereus—truly a grand sight. I am given to understand that such a number of blooms is very unusual, if not nearly unprecedented, in English gardens. May I ask that in some future number of the Journal a short note can be given relative to the usual character of the blooming of this most eccentric and beautiful Cactus? The plant promises on the whole nineteen blooms this season.—RICHARD HILTON, *Preston House, Faversham*.—[We will readily publish any notes we may receive on the Night-blooming Cereus.]

— **TESTING THE FERTILITY OF LAND.**—Whatever may be the "cranks" of our cousins (see page 436) on the other side of the Atlantic, I do not think that the principle will "hold water" that "Docks grow only on rich soil." Passing one of the poorest spots I know, which had just been under the steam cultivator, I could not help noticing that it had previously been, practically speaking, a mass of docks and couch grass, and considered too poor for cultivation to pay for the cost.—J. HIAM.

— **EARLY PEAS.**—Relative to the remarks on early Peas that have appeared in the *Journal* lately the statistics supplied by Messrs. Hurst and Son of Houndsditch are interesting. These show the early character of the present season as applying to the ripening of the first early Pea crops in their trial ground. The record extends over ten years as follows:—In 1883, June 21st; 1884, June 26th; 1885, June 24th; 1886, June 24th; 1887, June 25th; 1888, June 26th; 1889, June 16th; 1890 is not given, but as it was a hot dry summer the date would probably be the 18th or so; 1891, June 27th; 1892, June 15th, the spring having been dry; 1893, June 4th to 6th at the latest.

— **CAN PLANTS SEE?**—*Apropos* of this interesting question, may I mention a circumstance which occurred here last week? A man was engaged in putting stakes to some rows of Ne Plus Ultra Beans, and went away to his breakfast. On his return he found that the plant nearest to one of the last stakes he had put in had approached the stake and taken a turn round it, although he had been absent about half an hour only. Now it would seem likely that this plant had the power of vision, but how about the others in the same row, and also some rows that had been staked the previous day which had made no apparent advance to the stakes?—SCEPTICUS, *Salisbury*.

— **APPLE PROSPECTS IN DEVON.**—Having had to drive about forty miles last week gave me an opportunity of seeing many orchards, and in some parts, especially in the Exe Valley, I have never seen trees at this time of the year looking so bad. In some large orchards the trees had no leaves upon them, which not only means the loss of this year's crop, but injury for some time to come; in fact, the trees look as if they were dead. I noticed two orchards only divided by a small meadow, where trees in one were looking very well, and in the other very bad. In other parts the trees are looking well; but several owners of orchards tell me that the fruit is dropping fast, owing, no doubt, to the drought.—G. LOCK.

— **BULLFINCHES AND RASPBERRIES.**—The dry weather has made many enemies for the fruit grower in birds which, in ordinary seasons, give no trouble, and in our case this is particularly so with the bullfinch. Generally, bullfinches are associated with the destruction of fruit blossoms in spring, seldom making any further appearance in gardens afterwards; but at the present time we get more frequent visits from them than was the case in winter. Raspberries seem to be their favourite fruit. Chaffinches, tomtits, and other small birds all seem to have a tendency for fruit-eating, brought about, no doubt, by the long-continued drought.—W. STRUGNELL, *Rood Ashton*.

— **THE WAKEFIELD PAXTON SOCIETY.**—At the ordinary meeting of the members of this Society last week an interesting paper on "Plants in Pots" was read by Mr. J. Haigh of Sheffield. The paper was so much appreciated that the essayist received a pressing invitation to pay another visit to the Paxton Society, and to continue the subject. Mr. Haigh recommended amateur gardeners to study the nature and habitat of plants, and to treat them accordingly. He explained the best kind of compost and pots to be used for plants in pots; he strongly recommended good drainage with crocks, a little detail of much importance which is frequently overlooked, and he remarked that a plant requires water when, on the pot being tapped with the knuckles, it gives a ringing instead of a dull or heavy sound. Mr. Hudson of the Woolley Park Gardens had a fine display of blooms of Rhododendrons and Pansies.

— GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We are informed that the fifty-fourth anniversary festival dinner will be held at the Hôtel Métropole, on Thursday, June 22nd, 1893. Baron Schröder will preside, and a large and influential gathering is anticipated.

— GARDENING APPOINTMENT.—Mr. William Robert Coulson, for six and a half years general foreman in the gardens of John Crossfield, Esq., Walton Lea, Warrington, has been appointed head gardener to Joseph Verden, Esq., The Brockhurst, Northwich, Cheshire.

— A CENTENARIAN GARDENER.—As a rule gardeners live a long life, but comparatively few reach the age of Mr. John Cuckow, of Lenham, who, according to a Kentish contemporary, is now in his 102nd year, and still in possession of his faculties. Mr. Cuckow stated that this year he had cultivated the whole of his garden, which is about 9 perches in extent.

— LILIES AT WALTHAM.—Your printer has a good joke in my article on page 463, at the expense of Mr. Paul. He makes me say that Japanese Lilies are not cultivated at Waltham, inasmuch as they cannot find in that region "a congenial soul." The venerable rosarian will enjoy this immensely.—DAVID R. WILLIAMSON. [Printers will have their little jokes when they can, and say the best of the joke in this case is that the writer wrote "soul," and not "soil," as he perhaps intended.]

— THE LONDON PANSY SHOW.—In your report of the London Pansy and Violet Show of June 6th, at the end of your remarks on the trade exhibit of Violas and Pansies you add, "Messrs. Dicksons & Co., Waterloo Place, Edinburgh, competed in this class." We request you to correct this in your next issue, as we did not compete in any class, and merely sent a stand for exhibition.—DICKSONS & CO., *Edinburgh*. [We readily insert the correction. Our reporter did not observe any card on the stand indicative of its not being in competition.]

— GRAFTING IN SUMMER.—It is not generally known, but "Meehans' Monthly" says "that the longer scions can be retarded the more certainty there is of success. For instance, if grafts of Pear are cut in the winter, and put in the ground like cuttings, they will keep green without sprouting for months. The Pear tree to be grafted may push into leaf in May, but the grafting may not be done till June or later. The unsprouted cuttings used as grafts grow with surprising success. The writer has known some of these to be successfully grafted even at the end of July."

— CHRYSANTHEMUMS IN JUNE.—I send you a few blooms of Chrysanthemum Elsie, cut on June 5th, from a plant that came into flower early in November, and has flowered continuously ever since. Over 100 blooms equal to those sent were cut during April and May, quite as many in March, and the plant shows no sign of being exhausted yet. This I consider one of the best decorative varieties, and certainly an acquisition to a not too numerous section. I grow this variety without disbudding, as I do not think it nearly so good as when grown in a natural way.—P. S. [Truly a floriferous plant. The blooms were as good as we usually see them in November.]

— STRATAGEM PEA.—Mr. W. Strugnell, Rood Ashton, writes:—As a second early Stratagem is a fine Pea. We gathered some pods, June 1st, from plants raised in boxes the end of January. It is possible, considering the abnormally dry and warm spring, these would have been almost as forward sown outdoors, because of the check given them in planting out from the boxes for want of rain. They had an additional check, too, in a rather sharp frost in the evening following the planting, although protected by Yew branches inserted thickly among the rows. American Wonder sown and planted on the same dates on the same border was a little more than a fortnight earlier.

— HORTICULTURAL CLUB.—On Tuesday, June 6th, after the usual monthly dinner of the members, Mr. Chas. T. Druery, F.L.S., gave a very interesting lecture entitled "Round my Fernery," which he illustrated by a photograph embracing a considerable number of the finest forms of British Ferns as grouped in his fernery, and by a collection of freshly cut fronds from the most striking specimens. By means of these he demonstrated not merely the present great decorative value of these native plants, but also the practicability of enhancing their attractiveness by crossing, some very charming combinations being shown together with the parent forms. He also exhibited a series of graduated forms obtained by selective culture alone without crossing, and culminating in some of the finest plumose and crested forms existing. An interesting discussion followed, in which Sir J. D. T. Llewelyn, Bart., Mr. John Lee, and Mr. Cousens took part. Mr. J. S. Cousens exhibiting also a number of fronds of good varieties.

— THE ROSE ACACIA IN AMERICA.—It seems curious, says a correspondent, that the Rose Acacia (*Robinia hispida*), one of the most beautiful of flowering trees, will not flourish in America. It is said to have nearly disappeared from cultivation through the ravages of the locust borer.

— KALMIA ANGUSTIFOLIA ROSEA.—This plant is now flowering at Kew. It forms a neat low-growing bush, and produces medium-sized trusses of bright rose-coloured flowers in great profusion, which contrast beautifully with the light green shade of the young foliage.—A.

— ERICA CINEREA.—Where Heaths can be successfully cultivated this beautiful species and its varieties should be given a prominent position. At Kew it is now in full flower, the colour ranging in the many varieties from pure white in *E. c. alba*, to rich purple in *E. c. atro-purpurea*, and deep rose in *E. c. rosea*. Large patches of these varieties, grown on rockwork or the sides of hills, form a most attractive feature.—A.

— STEPHANOTIS FRUITS.—I send a double seed pod of *Stephanotis floribunda*. I have many times had one pod, but never had two on one stem before, and should like to know if any of your readers have seen the fruits in pairs.—G. LOCK. [The fruits are each 5 inches long, and  $6\frac{1}{2}$  inches in circumference, end to end like a pair of horns with the points outwards. We have seen similar examples, but very infrequently.]

— ROYAL METEOROLOGICAL SOCIETY.—At the ordinary meeting of this Society at 25, Great George Street, Westminster, on Wednesday, the 21st instant, at 7 P.M., the following papers will be read:—"Fifteen Years' Fog in the British Islands, 1876-1890," by Robert H. Scott, M.A., F.R.S.; "Upper Currents of Air over the Arabian Sea," by W. L. Dallas, F.R.Met.Soc. Mr. E. D. Archibald, M.A., F.R.Met.Soc., will also give an address on "Australian Climate and Weather," which will be illustrated by a number of lantern slides.

— HEDYSARUM MULTIJUGUM.—This is one of the most attractive of the rarer leguminous plants at present in flower at Kew. Growing about 18 inches high, it is admirably suited for a front position in the shrubbery, whilst it is equally valuable for the herbaceous border or for permanent beds on the lawn. The flowers are of a rich rosy purple, and are borne on racemes ranging from 9 inches to 1 foot in length, which are produced with the greatest freedom during the early summer. A rich, light loam is best suited for the successful cultivation of this charming plant.—A.

— THE ODOURS OF FLOWERS.—In one of his addresses on the odours of flowers, Mr. Meehan called attention to the fact that out of the 100,000 flowering plants known to botanists, possibly not 10 per cent. of them had any odour. The large majority of plants are in fact scentless. Among other points he called attention to the remarkable circumstance that in many large families there were only one or two sweet species; for instance, in the Mignonette family, of fifty species known, only the one in our gardens was sweet. Among 100 of Violets there are not a dozen sweet ones. In many other large families also, Begonia for instance, the scentless ones are as a hundred to one. Among our wild flowers the number of sweet-smelling flowers is very slim.

— WHAT BECOMES OF THE APHIS IN THE WINTER?—Referring to this question from *Nature*, on page 436, Mr. T. A. Sharpe does not say what species of aphis is referred to. In my researches for aphides in winter I have no difficulty in finding specimens of the Plum aphis in a young producing condition on the Plum bloom buds from January onward if the weather is mild. These I have shown in connection with the lectures under the microscope constantly, and advised fruit growers to take precautions by destroying with washes the mothers of millions in future generations during the coming seasons. Those who took the advice, and acted upon it in a practical form, have had excellent results. The great difficulty I find to contend against is the fixed idea that they come in the "east winds" in spring, and no amount of argument and ocular demonstrations will ever have any effect on some persons, and the only way that I see is to teach the young either with the aid of microscopes with specimens in different stages of growth and destructiveness, or with lantern slides with specimens from *Nature*. The Apple aphis does not appear to be produced in spring from hibernating viviparous mothers, as the Plum aphis, but from jet (bright black) eggs, which are not so easy to deal with, for as soon as they hatch out they retire within the tender foliage and become viviparous mothers in a short time, producing young at an incredible rate, curling up the foliage and sheltering from insecticides.—J. HAM.

— **VIOLA SPORTS.**—Mr. G. McLeod of Chingford has sent us a bloom of *Viola Duchess of Fife* with two distinct sports from the same plant. The flower of one sport is large, of good substance, and very attractive. The top petals are bright violet, the lower one being brownish yellow with a bluish margin and clear orange centre. This sport, we understand, is appearing on *Viola Duchess of Fife* in several parts of the country. The other, however, is the most distinct, and, so far as can be ascertained, has not appeared elsewhere. The flower is well formed and very pretty. A dark mauve colour characterises the top petal, this forming a pleasing contrast to the rich yellow centre, from which the lower petals gradually shade to a buff tint and well-defined heliotrope margin. It is very distinct, and if Mr. McLeod can "fix" it, there is no doubt it will become a popular variety.

— **STEAM *versus* HOT-WATER HEATING.**—The Americans obviously regard the British horticulturist as being behind the times in the matter of heating. Says "Meehans' Monthly," "Judging by the horticultural literature of the old world there seems to be a doubt whether steam heating can be made a great success, hot water being in general use there. The dread seems to be that steam requires much more personal attention than hot water. But American invention has so simplified things that it really requires little, if any more labour, to look after the houses, or a large series of houses heated by steam than when heated by hot water, while the advantage of carrying heat to long distances very rapidly are so much in favour of steam, that instead of its being a question with us as to whether steam or hot water is the best, hot water is really going out of existence."

— **ROYAL BOTANIC SOCIETY.**—Professor S. H. Vines of Oxford University gave his concluding lecture upon "The Leaf and its Functions" at the Gardens, Regent's Park, on Friday last. In defining transpiration as the power possessed by leaves of giving off watery vapour, the lecturer referred to the enormous quantity of moisture drawn by the roots from the soil, and by this means discharged into the atmosphere. For example, the common Sunflower was found to exhale 12 ozs. of water in twelve hours, and an Oak tree, with an estimated number of 700,000 leaves, would in the same way give off something like 700 tons of water during the five months it carries its foliage. While the other parts of plants varied but little, leaves, as befitted the most important organs, were able to alter themselves to suit the conditions under which they had to live, so that botanists were often able by the appearance of a plant to tell the climate and circumstances under which it had been grown.

— **TWO-OUNCE STRAWBERRIES.**—Fruits weighing 2 ozs. and upwards are not commonly obtained from plants grown in pots, although such records are occasionally given. Mention was made a short time since of Mr. Robinson's success with President Strawberry in pots at Heywood, Westbury, and since that date a crop of that fine variety *Auguste Nicaise* has proved even more remarkable than President. Several pounds could be gathered at one time, and out of these there were many Strawberries that weighed 2 ozs. each, and some almost 2½ ozs. Those accustomed to fruits of 1 oz. weight can readily imagine what a fine show these must have made both on the pots and dinner-table, and it is the more remarkable when the whole of the crop of nine fruits on each pot were of corresponding size. They were bright in colour, which is not a condition always presented in fruits of this variety grown in pots. A sunk pit is filled with Strawberries in pots in the spring, and the ventilation, in conjunction with fire heat, ensures a perfect set, hence the full size attained in the crops. A little air is left on all night, which keeps the atmosphere cool and dry, and prevents moisture settling on the flowers.—W. S.

— **THE ROYAL HORTICULTURAL SOCIETY'S FOUR DAYS' AUTUMN SHOW.**—A "Fruit Grower and Exhibitor" writes:—"As a Fellow and well-wisher of the Royal Horticultural Society, and as one who for several years past has been a large exhibitor in the fruit classes of the metropolitan, Crystal Palace, and provincial Shows, I venture to say that four days are too long to have hothouse and other choice fruits on view in an exhibition hall, inasmuch as a large per-centage of such fruits would be practically spoiled by the end of the Show. Under these circumstances I believe exhibitors who have enjoyed the privilege of showing specimens of their productions at the Shows indicated, will, bearing in mind their employers' interests, not compete at the Great Show to be held in the Agricultural Hall on August 29th and three following days; unless, while there is yet time, the Council of the Royal Horticultural Society give, through the medium of the horticultural press, a guarantee that exhibitors in the fruit classes at the Show in question may remove their exhibits at six o'clock on the evening of the

second day of the Exhibition. By complying with this very reasonable suggestion the Royal Horticultural Society would be serving its own interests, as well as showing that it was not unmindful of those of the nobility and gentry who annually support horticulture, not only with their subscriptions but also by allowing the produce of their gardens being staged at the leading horticultural shows, and a good display of fruit would result therefrom."

— **DISEASE IN CARNATIONS.**—During the past year or two a very troublesome fungus disease of a rust has appeared among winter blooming Carnations to the dismay of florists in America, cutting down the product of plants nearly one-half. It has been discovered, remarks "Meehans' Monthly," that this species of fungus belongs to the genus *Uromyces*, and on account of its affinity for the Carnation has been named *Uromyces caryophyllinus*. Like so many of these it easily gives away to the copper sulphates. Prof. Arthur says that the sulphates of iron, or green copperas, have been found to be generally as effectual as the sulphate of copper, or blue copperas. He says that there is already prepared in the drug stores a mixture known as copperdine, which is ammoniated copper carbonate. This ready preparation may be of great service to those who have not the time or disposition to make a mixture for themselves.

#### ROSE SHOW FIXTURES IN 1893.

 July 1st (Saturday).—Crystal Palace (N.R.S.).  
 „ 4th (Tuesday).—Bagshot, Diss, and Gloucester.  
 „ 5th (Wednesday).—Croydon, Ealing, Farnham, Hereford, and Lee.\*  
 „ 6th (Thursday).—Bath, Farningham, Manchester, and Norwich.  
 „ 7th (Friday).—Ulverston.  
 „ 11th (Tuesday).—Harleston and Wolverhampton.†  
 „ 12th (Wednesday).—Earl's Court and Tunbridge Wells.  
 „ 13th (Thursday).—Worksop (N.R.S.), and Woodbridge.  
 „ 14th (Friday).—Helensburgh.  
 „ 15th (Saturday).—New Brighton.  
 „ 20th (Thursday).—Bedford and Trentham.  
 „ 25th (Tuesday).—Tibshelf.  
 „ 27th (Thursday).—Halifax and Southwell.  
 „ 29th (Saturday).—Bedale.

\* Shows lasting two days.

† Show lasting three days.

During the present month a list of Rose Show fixtures will be issued each week, so that I shall be glad to have early notice of the dates of any shows not mentioned above, and also of any change of dates.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

#### CANTERBURY ROSE SHOW.

We are requested to say that this Show is put forward to Monday June 26th, on account of the earliness of the season, instead of July 4th as previously announced.

#### "THE WORM I' THE BUD" IN 1893.

"W. R. Raillem" (page 455) is quite right in supposing that I have not gathered so many grubs and caterpillars this year from my Roses as usual. Taking the same 1000 plants they fell short of the average crop in the previous five years by about 600, and were fewer than in any of those five years.—E. M., *Berkhamstead.*

#### CRIMSON RAMBLER ROSE.

We are informed that at the Exhibition of the National Horticultural Society of France, held recently, a gold medal was awarded to Mr. Charles Turner, Royal Nursery, Slough, for his Japanese Polyantha Rose, *Crimson Rambler*. The plant was packed in an ordinary matted basket, and forwarded by rail to M. Margottin fils of Pierrefille, and when unpacked it was found not a flower or petal had dropped, showing its persistence and its adaptability for sending long journeys. A brief description of this grand Rose was published in the *Journal of Horticulture* for May 25th.

#### THE DUCHESS OF BEDFORD ROSE.

The raiser of the *Duchess of Bedford* Rose was Mr. Richard Broadhurst Postans, and not, as stated by Mr. Williamson in your last issue (page 463) Mr. William Paul, although the latter may have assisted to introduce the Rose to the public. Mr. Postans was an enthusiastic

amateur who not only grew, but also raised several valuable Roses in the years 1878 to 1881. In 1879 he raised two out of the five new Hybrid Perpetual Roses of that year—viz., Duchess of Bedford and Countess of Rosebery. Lady Sheffield and May Quennell were also raised by him.—HARCOURT P. LANDON.

#### ORANGE FUNGUS ON ROSES.

WHEN all are singing the glories of the Rose it may seem unpleasant to call attention to one of its most malignant and besetting diseases. It is, nevertheless, an old and approved practice at seasons of enjoyment to introduce mementoes of the final destiny to which all must succumb. Disease is by no means a welcome topic, but it is well to remember that the beautiful has to contend with foes which seek to bring it down to

perfectly healthy and showing flower buds. Here was the contrast—wood lean, impoverished by the leaves in the preceding year being preyed upon by the orange fungus; wood stout, well nourished by clean healthy leaves the year before.

In fig. 87 at A is shown a bud of the Dog Rose (*Rosa canina*) attacked by orange fungus or "rust" (*Lecythea Rosæ*). It was sketched on May 1st, 1893. When gently tapped on the table the spores were shed as at *a*. On May 8th, 1893, a bud, similar to A on May 1st, had attained the condition shown at B, and the slightest tap of the end of the shoot on the table caused the spores to be liberated as at *b*.

To show the spread of the fungus another infested bud and growth from it was selected on May 8th, 1893. It will be noticed that the fungus has attacked the young wood as indicated by the "black" in the

FIG. 87.—ORANGE FUNGUS ON THE DOG ROSE.

a commonplace level. Instead, therefore, of the subject now being broached having a depressing effect it cannot do otherwise than good.

Where does the orange fungus come from? That question was asked over thirty years ago, and it has remained practically unanswered. But I set myself the task to find out the facts. "Rummaging among the mysteries," looking into every corner and tumbling over things, only revealed the fact that orange fungus was found on Rose leaves. The authorities were unanimous as to its being a native, therefore it would be found on some indigenous species of the Rose. With the knowledge gained from such authorities as the late Rev. M. J. Berkeley and Dr. Cooke, I looked for the orange fungus in Nature—scanned every wild Rose bush I came across, and found a complete answer to the question, "Where does orange fungus [on cultivated Roses] come from?"

On a high and dry bank, about a mile distant from St. Alban's Abbey, I found growing, in a gravelly loam, a bush, about 8 feet high, of the Dog Rose (*Rosa canina*), with a number of the orange-coloured buds. The parts of the bush on which these conspicuous orange-coloured buds grew were much smaller and weaker than the other parts, which were

engraving C and the growth distorted in the bud, whilst the shoot inclines towards the weakness, and instead of taking an upward—a resistive—grows in a downward non-resistive direction. The fact is it has capitulated to the enemy, for the fungus cannot find a lodgment for its spores on the smooth upper surface of the leaves, nor gain access to the internal tissues upon which it lives on that side unless the conditions are exceptionally favourable. It will also further be observed that when such shoot is held upright and its end lightly tapped on a table that the spores do not fly upwards, but follow Nature's undeviating law of gravity, and descend as shown at *c*, for they cannot float in still and dry air. Sometimes the fungus entirely encircles the attacked shoot, then it suddenly collapses; it has gone off without cause or reason, and the leaves will be found very pale in colour and extremely thin in texture; but this does not always happen, for the wood becomes too firm, and the callus thrown out on the part of the Rose bars the further progress of the fungus. The result is an ungainly scar, and is termed canker.

The bud affection must have been common in Shakespeare's time, for he frequently alludes to cankerous buds, and they are easily found if

examined, but most are due to the burrowings of larvæ, about which we are not at present concerned, therefore my remarks will be confined to the fungus. This first appears in the buds of the common Dog Rose, so much employed for standard Roses, but I do not consider it has been introduced into gardens in that way, for the stocks are merely sticks with dormant buds, and few if any are attacked by the fungus in nursery rows. It is worthy of note that the bud form of the fungus does not produce the mature form; at least, I have not found any, and the fungus has disappeared from the bud or shoot by the time the "brand" is well developed in the leaves, nothing remaining but the cankerous hollow scooped out by the fungus; in fact, it becomes a receptacle or "run" for water, and it is then all "up" with the spores of the *Lecythea Rosæ*, as they must in warmth and moisture do or die.

We have seen how the spores are scattered, also that the fungus distorts and causes the growth to grow downwards, and this acts as a rest for the spores, the under sides of some leaves being semi-upwards, and strive as the Rose may it cannot reverse them in a moment, for it is a work of time, and by when the leaves are turned face upward—that is, the right way—one or more of the invisible (to the naked eye) particles of dust has pushed its or their germ tube or tubes and entered through the stomata into the interior of the leaf or leaflets. The turning upwards of such leaves only aids the fungus by elaborating the substance upon which it exists, and is essential to the reproduction of the species. In the bud that substance is the cambium; in the leaves it is the chlorophyll. After a time the leaves assume a sickly jaundiced hue, and brownish spots appear on the upper surface, as shown in the engraving at D. But the marks are not remarkably conspicuous on the upper surface of the leaves; yet the brown patches and the jaundiced hue, which overspreads so much of the leaf surface has as been penetrated by the mycelium of the fungus, are a clear indication of trouble from orange fungus. This must be sought for on the under surface of the affected leaves, where will be found little masses of a brilliant golden yellow or orange colour. These masses consist of spores—the succeeding generation from the bodies, at one time present in the buds, which have been scattered far and wide by the wind, and have found a suitable host—one affording them the elements needful for germination, development, and reproduction—a healthy, vigorous, and hitherto a flourishing Rose tree.

This form is the orange fungus or "rust," and being scattered by the wind or otherwise falling on Rose leaves, and finding a fitting nidus they reproduce the fungus (*Lecythea Rosæ*). If the golden yellow masses on the leaves are examined carefully there will be found amongst the orange-coloured dust several little deep brown specks, which under the microscope appear as at E, and this form is termed the "brand." Had the fungus been examined at an earlier stage by the aid of the microscope it would have been found that the orange-coloured cells (spores) and the barren cysts (abortive cells) were supported together on slender stems and in clusters. If the golden-yellow dust be examined with a lens it will be found to consist of myriads of semi-globular cells, mixed with a less number of colourless cells of slightly different shape, and concatenate (chained together), as at F. The orange powder is conspicuous: it consists of the summer spores called "rust," the deep brown specks are the winter or resting spores, termed the "brand." With the aid of a microscope of higher power the latter will be found to consist of sausage-shaped bodies, standing on colourless slender stems as long or longer than themselves. Each of these deep brown bodies is several times contracted, as though it had been tightly bound with slender cords, and the surface has been studded with minute glassy warts. The general appearance of the "brand," highly magnified, is represented at G. Each "brand" consists of six to eight-celled spores. In this stage the fungus is known scientifically as *Phragmidium* (*Aregma*) *mucronatum*, *Fr.*, or *P. subcorticium*, *Schr.*

The autumn having arrived the leaves fall; the Rose is considered as safe from attack as the fungus is against cold and wet. But the Rose has some of its twigs broken by wind, nipped by cattle, or cut off, and the consequence is some of the buds are started into growth—it may only be a little, as shown at H, yet it is enough to admit one or more of the cylindrical multiseptate spores of the *Phragmidium* at I. Whether it set to work then or later it amounts to the same thing—that bud will assuredly produce the condition shown at A, B, and C in the early part of the following summer. The "brand" spores may, in some cases, pass the winter in their frostproof and watertight coats, and in spring separate and float in the air like balloons. But it is better to take preventive measures against the recurrence of the fungus where there has been an attack than to speculate in microscopic probabilities, for one thing is certain—namely, many of the winter or "resting" spores find billets on the Rose trees and abide there ready to germinate and push their mycelium into the stoutest Dog Rose or the most fair and beautiful Rose of the garden. It is only a question of spores and a fitting soil. The spores cannot enter a closely sealed bud, as at I, nor can they make an impression on smooth, clean, elastic bark. A vigorous growth from a similar bud to I, taken from the same bush, as A, B, and C is shown at J, all from living specimens, and natural size, except E, F, and G, which are highly magnified representations.

The only remedy is to kill the spores. All the arts of cultivation will not avail one jot against the fungus. It is an excellent practice to remove all the fallen leaves in autumn and burn them, also to not shorten the shoots in autumn so as to start the basal buds *etc.*, but leave enough wood above the pruning buds, so that any growth taking place may be on that part, and if any spores are billeted there they will be removed with it at the usual pruning time. Instead of Roses

being pruned early, as formerly, they are now pruned late, which accounts for the decreased infection of Roses in gardens by the orange fungus, and when it does appear it is generally on the leaves. We have seen where the spores that produce it come from, and those that wish to avoid its attacks must scan the Dog Roses in the immediate locality, and nip the disease in the bud (A), which contains, according to calculation on the microscopic scale, more spores than there are cultivated Roses in the county of Hertfordshire.

Another excellent practice is to bury the diseased leaves, or if the leaves are cleared away and burned dig the ground, so as to bury the resting spores after sprinkling a little sulphate of iron evenly on the ground, say a quarter of an ounce per square yard. I am assured that this is a good manure for Roses in soils deficient of iron, and most parasitic animals and vegetables hate sulphur.

These, however, are empirical, and the conclusions or deductions drawn from the supposed effects mere fancies or delusions; therefore, we will combat the fungus. 1, Spray the bushes whilst the pruning buds are quite dormant with sulphate of copper, according to the formula hereafter given, for simple sulphate of copper solutions must be used with great care on plants liable to attacks of "rust" and "brand" as the Raspberry and the Rose. 2, Spray the trees when they are in bud, and before the flower buds appear clear off the leaves with copper sulphate, 4 ozs., fresh burned lime unslaked 4 ozs., water 7½ gallons. Dissolve the sulphate of copper in one vessel and slake the lime in another, forming the lime into a thin whitewash, and then pour it slowly through a hair sieve into the copper solution. Dilute to 15 gallons for this early spraying, for the foliage is as yet tender, and remember that every part of the plants, especially the under side of the leaves, must be coated with the finest possible film. 3, When the first crop of flowers are all gathered or blown spray the trees with the mixture at full strength, and it may safely be concluded that the Roses are orange fungus proof. If the fungus gain access to the tissues of the leaves the spraying may need to be repeated, but do not give an overdose.—G. ABBEY.

## FRUIT PROSPECTS AROUND LIVERPOOL AND IN CHESHIRE.

BLACKLOW HOUSE, ROBY.

APPLES form a good average crop here, the best being Irish Peach, Mank's Codlin, Ecklinville, Hawthornden, Bedfordshire Foundling, Lord Suffield, Lord Derby, Blenheim Pippin, Betty Geeson, Brabant Bellefleur, Nelson's Glory, Flanders Pippin, an admirable Apple, and one which never fails; Ribston, and Golden Noble. There is a very moderate crop of Pears. Doyenné du Comice, Pitmaston Duchess, Beurré Clairgeau, Beurré d'Amanlis, Beurré Diel, Beurré Capiaumont, and Beurré Bosc, Fondante d'Automne, Citron des Carmes, Jargonelle, Grosse Callebasse, and Glou Morceau are the best. Cherries are nearly a failure. Gooseberries, the heaviest crop known for years, and not the slightest trace of the caterpillar. Plums, with exception of Victoria and Orleans, are a complete failure. Strawberries, a fine crop, fully a month earlier than last year, having already gathered Duc de Malakoff, Keen's Seedling, and Black Prince outdoors. Black and Red Currants made a grand start, the former being now nearly *nil*, but the latter very plentiful. Raspberries are carrying an enormous crop, but we have to keep them plentifully supplied with water or the crop would be lost. With regard to Pears I may say that many have succumbed to the attacks of the weevil, which this year seems to have been a great plague.

COURT HEY, BROADGREEN.

Here the fruit crops are more promising this year than last, but everything is suffering from want of rain. All varieties of Apples are good. Pears an average crop; Jargonelle, Beurré Diel, Beurré Clairgeau, Durondeau, and Marie Louise are good on walls; and Williams' Bon Chrétien, Louise Bonne of Jersey, and Marie Louise on dwarf trees. Gooseberries and Red Currants are a full crop, Strawberries promise well, Cherries on walls a failure owing to the dry season.

ENDFIELD HOUSE, AIGBURTH.

Apples are extraordinarily good. Of Pears Mr. Kelly has a fair crop, Jargonelle, Pitmaston Duchess, Marie Louise, Beurré Clairgeau, Beurré Diel, Beurré Bosc, Autumn Bergamot, and Winter Neli being the best; Glou Morceau, Brown Beurré, Gansel's Bergamot, Doyenné du Comice, and others are complete failures. Plums form the heaviest crop for many years, noticeable being Green Gage, Prince Albert, Queen Victoria, Kirke's, and Coe's Golden Drop. Cherries seldom do well with the exception of Morellos. Gooseberries, Red and White Currants are exceptionally good, whilst Strawberries are abundant, but, like all others, suffering from excessive drought. The four latter are almost a month earlier, Black Prince Improved and Noble having been gathered, and Duc de Malakoff colouring fast.

CALDERSTONES, AIGBURTH.

Mr. Tunnington considers all outdoor crops fairly good, Peaches and Nectarines, which are always done so well here, being especially fine. Apples are, in nearly all cases, good. Pears not so heavy, only about half a crop. Plums and Damsons are very poor, whilst Apricots are carrying fair crops. Black and White Currants and Raspberries form a full crop, and Strawberries are excellent. Rain is badly wanted, watering and mulching having had to be resorted to to save the crops.

## RAINFORD HALL, ST. HELEN'S.

Here the fruit is looking fairly well. Gooseberries, Currants, Cherries, Plums, and Apples are all carrying heavy crops. Pears are very fair, and Strawberries first-rate. They have had to be watered or they would not have been so good. All kinds of crops are very early, but badly wanting rain.

## CHRISTLETON RECTORY, NEAR CHESTER.

This is a notable garden for outdoor fruit culture, and where the Rev. L. Garnett exhibits he is always in the first rank. I was informed that Apples generally are good and promising well. Pears are only moderate. Stone fruits generally are very good. Peaches and Apricots are excellent; Cherries, Damsons, and Plums a full crop, the latter being, however, much infested with insects. Strawberries are suffering a little from drought, but form a good crop. Plenty Raspberries and Gooseberries are good, but the latter have been troubled with the caterpillar. Currants thin, though at first there was a good promise. On the whole the prospect is considerably above the average.

## HOOTON HALL.

Mr. Hanagan has what he considers the best all-round crop of fruit that he has had for the last twenty years. Apples, heavy crops; Pears, most varieties plentiful; Plums, moderate; Apricots, good; Cherries, heavy; Strawberries, very good. Peaches and Nectarines not much grown here. Gooseberries, Currants all heavily laden. Of Cob and Filbert Nuts very few. Here as elsewhere all fruit trees and bushes are badly in want of rain.—R. P. R.

## ABOUT HULL.

## TRANBY CROFT.

HULL, city of docks and dockers; huge artery of commerce of which the corpuscles assume all shapes and forms, from Norway fir to Dutch margarine, from thrashing engines to crockery, is remarkable for many things, but not for flowers. Where in this huge conglomeration of docks and streets, in which towering spars and lofty chimneys vie with each other for superiority of altitude, one can taste the pleasures of a shower bath in the superfluous water from an overhead window sill, I cannot, despite assiduous search, proclaim. There is water enough to be sure, fresh and salt, clean and dirty; but of plants to enjoy it there are too few to redeem the character of the old town for dullness. Taking the place as a whole, one looks in vain for trim front gardens, creeper-covered walls, or flower-furnished windows. Perhaps the tastes of the average inhabitant are somewhat too robust for such delicacies; but if we wander forth a few miles from the city, in the gardens attached to the homes of the great men of Hull, we find much of the material which goes to build up the fine shows held in the dock town in autumn.

It is easy to arrange a pleasant round. My own limited knowledge of the locality was expanded by some acceptable hints from one who is held in high esteem at Hull, horticulturally and otherwise—Mr. R. Falconer Jameson, but whose energetic spirit was then tamed, unfortunately, by a severe illness. Those who have no such guide will be likely enough to find their thoughts passing from such of the eighty-six magnificent Wilson steamers as are to be found in the docks to the Wilson residences, and so by a natural transition it will not be surprising if the next objects of admiration are the houses and gardens of Tranby Croft. This beautiful demesne, the property of Arthur Wilson, Esq., is about five miles from Hull, and as two or more out of the five may be covered by tram, and the remainder is a very pleasant highway, it is by no means unwise to go by road. But Hessle station is only two miles away, and an agreeable day may be spent by visiting Hesslewood and Swanland Manor as well as Tranby Croft. The three places, about all of which I propose to say a little, are within comfortable walking distance of each other, and all are thoroughly worthy of a call.

The white walls and square towers of Tranby form an admirable guide, seen as they are through the trees. They serve the same purpose as the lofty Wilberforce monument in Hull town, which focuses the ends of the principal thoroughfares in itself, so to say, and is therefore a good landmark. A handsome lodge and a long avenue of Conifers interspersed with shrubs mark the entrance to the Croft. Near the lodge some flower beds were being filled, and superintending the work stood an upright, keen-looking man whom I rightly took for the head gardener, Mr. J. P. Leadbetter. The fact of our not having previously met did not detract from the warmth of his welcome. One may almost say that Yorkshire is pleasant if only for its welcomes. A stranger is not greeted with finicking hesitation, but with quite an abandonment of heartiness. If there are two or three to do the welcoming each seems as though he would like to carry off a slice if he cannot have all the spoil. In this case there was only one, and embarrassment was saved. I am not going to attempt any description of Tranby Croft from an architectural point of view, for, sooth to say, its beautiful setting of Conifers, shrubs, and flowers proved so attractive as to monopolise all notice. The pleasure grounds are indeed delightful. The beds in front of the house were just filled. One of scarlet Begonias, with *Gnaphalium lanatum* to cover the ground, will be beautiful when completely furnished, and so will others composed of *Pelargonium Chelsea Gem* and *Iresine*, *Pelargonium Manglesi* and *Ageratum*, Begonias and variegated *Dactylis* respectively. Near them there were two magnificent banks of *Rhododendrons*, and the lawns are broken by many objects of interest, such as fine plants of *Abies Parryana glauca*, of splendid habit and colour; a grand *Cedrus*

*Deodara robusta*, a fine *Taxodium sempervirens*, *Abies concolor*, and beautiful arches of Honeysuckles and Roses.

Most visitors are likely to feel special admiration for a Conifer-lined walk that is a favourite promenade of Mr. Wilson. Some perfect plants of *Cupressus Lawsoniana*, 30 feet high; *C. L. erecta viridis*, 10 feet high and of faultless shape; *Cryptomeria elegans*, *Thuja borealis*, and *Abies Douglasi* will be particularly noted. Huge shrubs of white Broom laden with blossom were amongst them. But a glimpse of the Palm house should be taken before seeking other parts of the grounds. The amount of furnishing carried on is enormous, and superb plants of *Kentia Belmoreana* (16 feet high), *K. Fosteriana*, and *K. Canterburyana* do good service. There is also a gigantic specimen of *Phormium tenax variegata* 12 feet high, a fine *Cycas revoluta*, and other good plants. The fernery contains some beautiful objects. There is a grand plant of *Acrophorus emersii*, 5 to 6 feet through; a splendid *Adiantum concinnum latum*, 4 feet through; *Microlepia hirta cristata*, nearly 7 feet across; and noteworthy specimens of *Davallia Mooreana*. Some of these Fern giants have worthily represented Tranby Croft at many exhibitions, and are likely to make their quality felt in the future. *Asparagus deflexus* is excellently grown, and proves very valuable. There are many admirable Crotons, *angustifolius* and *Weismanni* being two of the best of a clean and healthy collection, in which *Anectumensis*, *Warreni*, *Aigburth Gem*, *Mrs. Dorman*, *Superba*, and *Flambeau* are also conspicuous for quality.

Two houses planted with young Vines four years ago are the fore-taste of the fruit department, which is as well managed as the others. One contains Muscat of Alexandria, Madresfield Court, Mrs. Pince, Alnwick Seedling, and Duke of Buccleuch; the other, Lady Downe's, Alnwick Seedling, Mrs. Pince, Gros Maroc, Gros Colman, and Black Alicante. These have made first-rate rods, and carry excellent crops. Between this and the other range, in which Black Hamburgh is just ready with plenty of 2 and 2½-lb. bunches, is a corridor of Figs growing like Willows, and now swelling up their second crop. Two thousand Strawberries are forced. Vicomtesse Hericart de Thury, Auguste Nicaise (which does exceedingly well), La Grosse Sucrée, and Helena Gloede being the four standard varieties. The Peaches and Nectarines are models of good management. Lord Napier, Grosse Mignonne, and Violette Hâtive are finishing splendid crops. Alexander is now cleared, the first fruit having been gathered on April 15th. This valuable but eccentric Peach gives no trouble in the way of bud dropping or non-stoning at Tranby. The supply of Peaches is carried on to the second week in September. Mr. Leadbetter is a strong believer in summer pruning, and the trees speak eloquently of skilful treatment.

Violets are very extensively grown, and so are Roses in pots, and planted out under glass. Bushels of the latter are cut, the varieties comprising Safrano, Souvenir de Gabriel Drevet, Etoile de Lyon, Sunset, The Bride, Climbing Niphetos, Jardin des Plantes, Madame Lambard, Jean Pernet, Catherine Mermet, Comtesse de Nadaillac, Souvenir d'un Ami, Grace Darling, and Rubens—by no means a bad selection. Early Gladioli are largely grown in pots, and so are Begonias, tree Carnations, and Tuberoses. Amongst Orchids *Cymbidium Mastersi* and *Aërides Lobbi* are well represented; Disas grow like weeds, while Cattleyas, *Ceoloyncs*, and *Calanthes* are extensively and well cultivated. The herbaceous borders are a beautiful feature of the place. One long border has been glorious with huge masses of *Doronicums*, and is now brilliant with large clumps of *Hemerocallis flava*, *Inula glandulosa*, Lupins, and Pæonies. It would be easy to enlarge upon them, as also upon the well-managed kitchen garden, wherein Peas were gathered at the middle of May, and Cabbages from July sowings cut in the early part of April, neither a bad result for a northern garden; but one can only touch lightly on a few features of the place, leaving its true pleasures to be learned by a visit.

The recollections of Tranby Croft will be of a beautiful estate of which the resources are developed to the utmost by thought and skill. It is not a Sleepy Hollow, where matters go at a comfortable jog trot, but a noble home where hospitality reigns supreme, making heavy demands on the supply of fruits and flowers. Alert and energetic, Mr. Leadbetter is the sort of man to see that his department is not found wanting, indeed an impression is gathered that the lively atmosphere which prevails is more congenial to him than one of a soporific character would be. The gardens and grounds may be expected to grow in interest and beauty as the Conifers which enrich them develop further. With the judicious thinning that their number may perhaps be thought to demand some of them should grow into magnificent specimens, otherwise they may suffer from an embarrassment of riches. There can be few visitors to Tranby who will not desire to make another call in the fulness of time, and when the opportunity arises for doing so the visit will be paid with the fullest confidence that an already beautiful place has grown in distinction and charm.—W. P. W.

## "THE SCOUNDREL SPARROW."

IN defending the sparrow it was certainly not my intention to be discourteous to "W. R. Raillem" (page 444), and I regret to have given him any reasons to think so. As I truly believe that the sparrow is not an enemy, but man's close companion and friend, the same as are our feathered songsters generally, I perhaps do write with somewhat strong feelings, the more so believing that through man's regrettable negligence, if not even unpardonable ignorance, birds are grievously wronged. As also were my parents, I, too, depending on garden produce

for my bread, I regret that I once had prejudices similar to those that your correspondent now possesses, but which, after much thought and close observation, have now entirely disappeared. And certainly my experience is practical. I have been favoured by an all-round experience, and since a very severe frost some fifteen years ago, having given special attention to the good and—yes, evil properties of sparrows and others of the hard-billed birds, and also to the unadulterated good of the more continuous insect-eaters, my position now is that of one not only experienced, but firmly grounded in the conviction that, with sparrows included in particular, birds grouped are good to mankind. To ignore that hither and thither there are not found those who have just reason to complain of vexatious depredations would be an injustice that fact does not justify.

Rather than simply describing the sparrow as “a feeder of seeds and vegetables,” it would be more correct, in populous towns especially, to describe him as a scavenger, and a bird that by its practically continuous attention to the ashpit and gutters purifies our atmosphere by clearing away unconsumed portions of flesh and filth, of which much accumulates near human habitations. But have your readers never observed how closely the sparrow copies man’s ways? He loves his home, he loves for food a good mixed dish, and he even delights in and takes his few weeks’ holiday, but, wise bird! just at the time when the new corn is in the milch state, a pleasant change to the palate, is desirable for his health’s sake. So it was, I suppose, that the cottager (page 445) was left with but the valueless straw to winter on. The grower had neglected to protect, as some easy people do their Apples from boys; and the sparrows, which cleared off the bloom of “W. R. Raillem’s” Apple tree, would, I suppose, also hold equally high festival.

But I suppose I must now proceed to give more tangent reasons for the faith that possesses me. Having nailed my colours to the mast I must justify how even a fruit grower can delight in birds. It is admitted of both birds and animals that they possess wonderful instinct. It is the same truth—man’s brain, with kingly pride, reigns over and subdues. Man as he marches on to futurity is a gatherer by the way; he probes deeper and still deeper, and so grows in wisdom. “W. R. Raillem” must tack his Apple tree to mine, and we must divide the average crops. If necessary he must even uproot it, as our noble army of engineers supersedes faulty vessels. He must look upon his pillaged Apple tree as the engineer looks upon the too-frail storm-tossed barque, not neglecting to recognise that these are simply difficulties destined to be overcome. In looking into Nature’s laws we find it more deeply engrained than man possibly can engrave that we must labour and cultivate, difficulties being the forerunner of knowledge, they making cultivation a necessity; and troubles, whether arising from the untamable elements, from the lowly sparrow or from any other cause, we must not risk ignorantly, but make sure only by wisdom’s ways to overcome them.

The sparrow’s nature is this. Near populous places where table sweepings are plentiful he will, whilst neglecting caterpillars, eat more or less green food as the nature of the more solid food secured necessities. On the contrary, if encouraged to breed in the open country, where the kitchenmaid’s delicacies are scarce, then he will during the blooming period greedily devour caterpillars, as my home-bred sparrows have now done for years, and without, except when the ground is wrapt in snow, so far as I can discover, ever even touching leaf or bud. Save the holiday period spoken of, they go poking about among the trees all the rest of the year, and so it is that, though I could do with a few extra hands during May and June, they succeed in protecting my crops from harm. But to expect such protection near large towns or near vicinity stackyards is folly, as the harder the food the more is greenstuff a necessity to birds. In such places, feather as preponderating over foliage, so we have a sample of these disasters out of which man’s desirable robustness grows.

As to the soft-billed, or more especially insect-eating birds, in the north we have them in too few numbers, and far too little with us, and but for the sparrows fruit crops would be a failure. I certainly would consent to replace that unneighbourly specimen that copied man so far as to attempt to take the martin’s house and goods, but as I do not breed such bad characters I have no reason to do so. As to getting worse, that, too, I hold as not satisfactorily proven, and attribute such charges rather to the cheaper press of these recent times, to greater facility in reporting such asserted retrogression. Sparrows, too, are quickeners of gardeners, not parasites on them; and did they in all cases succeed in moving gardeners’ brains to greater activity as they have frequently moved mine, so much the better would it be for gardeners and the commendable trade to which they are already so much credit.—JOSEPH WITHERSPOON.

WHEN at home much of that which I term my restful time is spent either in my gardens or in my little wood. It amounts to some hours a week, and this is for the observation of bird life and natural objects. I have read with attention the correspondence that has lately appeared in the *Journal* about sparrows. To me it is a very curious fact that there are some who deem the bird entirely a saint, while others aver that he is “an awful sinner.” Surely there must be “sparrows and sparrows”—sparrows good and sparrows bad; sparrows possessed of an evil spirit, besides those whose “ways” are all that can be desired. I am sorry to say that I have never had the good fortune to have a colony of the latter about my premises. We are told by one writer that the reason the sparrow is so very naughty is because he wants water; if he has that put for him he will not peck out the fruit buds. Now it so happens that I feed my birds well every day, and there are three

pans of water put for them, which is “refreshed” two or three times a day. One would think so good a bird as the sparrow is represented to be by some that he would have some feeling akin to gratitude for “past favours;” but if so he has a decidedly queer way of showing it unless he mistakes my desires, for he annoys me beyond endurance by pecking off all my Primrose flowers, my Crocus, and many other things he does that are equally wicked. In fact, I have a horror and a detestation of him, and would gladly be without him, in spite of all the good that he is said to do.

In my garden he is most troublesome and quarrelsome. He drives away my whitethroats, my blackcaps, and fights my thrushes. Some half wild Barbary doves came into my wood, when directly they settled the sparrows “went at them” and drove them away. I wish that the sparrows and the bullfinches would gratify those who see so much good in them by never leaving their orchards and gardens. I am fully aware of how the sparrows feed their young when they can get it—that is, on insect life; but this is only the first week of the nestling. After then they begin to give them grain, buds, or anything that they think suitable. “W. T. B.” (page 463) says he never saw them pick Croci. I have, and watched them patiently, and seen them tear off the blooms and throw them down by the dozen; and so with Primroses. As to their stopping water pipes, I stop that by putting wire netting over the tops. “W. T. B.” says the “hedges were swarming with various caterpillars,” and his sparrows cleared them. All I can say is that his colony are the “saintly” sparrows. I never knew any bird that would eat “various” kinds of caterpillars. Most birds have their particular kind of food, and will not starve in what be a land of plenty to others.

“W. T. B.” seems to think that sparrows are more destructive than formerly. One reason is that there are more of them. Fifty to sixty years ago here in Kent there were numbers of sparrow clubs for the purpose of destroying these “pests.” At this time barns were thatched, and I have seen the carter and his lad go round the buildings with a ladder and take hundreds of eggs of the sparrow in a few evenings, and also some time was spent in clearing them out of the martins’ nests. At that time I know, and which is contrary to the statement of “W. T. B.,” that they spoilt many rows of Gooseberry and Currant bushes. Lately, while watching some up in an Oak tree nearly over my head, I saw them time after time break off young twigs and throw them down. I examined several of these, and could not find a trace of an insect, and the twig was broken off at the woody, not the green part. This sort of thing still goes on, though they come to the water pans, and not only drink but wash in them. Be sure it never was called “the mischievous sparrow” for nothing, but it is so called, and I can vouch that in that way it not only has no equal, but by a long way it is unapproached.—HARRISON WEIR.

## THE DAHLIA.

[A paper read before the members of the Sheffield Floral and Horticultural Society by MR. M. H. WILLFORD.]

IN the introductory notes of this paper I have taken a few extracts from G. Glenny’s book on “Florists’ Flowers,” relating to the introduction of the Dahlia shows, and the rules laid down as to what should constitute a perfect flower.

The Dahlia was introduced to this country by the Marchioness of Bute, who brought the first species from Spain in 1789; but this plant was soon afterwards lost, other species found their way here, and they were bloomed in due course. During the next ten or fifteen years the Dahlia was taken in hand by the florists of Holland, France, and Great Britain, and they produced flowers far surpassing in beauty those from which they were raised.

At the period when the varieties were first becoming numerous there was every conceivable shape, size, and colour (excepting blue). There never was a plant so likely to be destroyed in value by the eagerness to multiply the sorts on sale, and the enthusiasm of the public to cultivate the largest collection. There was not at this time any notion about beauty; singularity was the first object, and brilliancy of colour went a long way towards making a flower singular.

The leading florists in England thought that a check might be put to the wholesale raising and putting on the market of so much objectionable stuff, which would be sure to disgust the public with the flower, so they established a show at Billingsgate, when a 5-guinea cup was given as a first prize, and the money paid for entrance was divided into second and third. These were given for the best twelve double flowers. The next show under the same auspices was at Hammersmith, when the first medals were issued in the name of the Metropolitan Society, not then fully organised. The result of this was the public abandonment of all but the proper double flowers. The publication of the “Properties of the Dahlia” in the Horticultural Journal banished all others from the garden as well as from the shows.

The following is an outline of the properties laid down for the perfection of the Dahlia:—

1st, The flower should be a perfect circle when viewed in front. The petals should be broad at the ends, smooth at the edges, thick in

substance, perfectly free from indenture or point, stiff to hold their form; they should cup a little, but not enough to show the under surface; they should be in regular rows, forming an outline of a perfect circle without any vacancy between them, and all in the circle should be the same size, uniformly open to the same shape, and not crumpled.

2nd, The flower should form two-thirds of a ball when looked at sideways; the rows of petals should rise one above another symmetrically; every petal should cover the join of the two petals under it, what florists call imbricating, by which means the circular appearance is perfected throughout.

3rd, The centre should be perfect; the unbloomed petals laying with the points towards the centre should form a button, and should be the highest part of the flower completing the ball.

4th, The colour should be dense, whatever it be, not as if it was a white dipped in colour but as if the whole flower was coloured throughout. Whether tipped or edged it must be free from splashes, blotches or indefinite marks of any kind. If the petals show the under side too much, even when looked at sideways; if they do not cover each other well; if the centre is composed of petals pointing upwards, or those which are round the centre are confused; if the petals are too deep and funnel-like; if the petals are too narrow or exhibit too much of their length, or if they show any of the green scale at the bottom of the petals; if the eye is sunk, if the shoulder is too high, the face flat, or the sides too upright; if the petals show an indenture as if heart-shaped; if the petals are too large and coarse, or are flimsy, or do not hold their form, in any or all these cases the flowers are objectionable, and if there be one or two of these faults conspicuous the flower is second or third rate.

After these notes as to what a good Show Dahlia should be we will now think about the cultivation of them, along with the later introduction of the Pompon, Cactus and Decorative varieties.

The first thing to consider is the preparation of the ground. A position should be chosen where they will have as much sun as possible, but sheltered from the rough winds. Some growers advise manuring in the autumn and turning up the soil, leaving it rough all the winter, so that the frosts will sweeten it by planting time, others prefer roughing up the ground in autumn and manuring in spring. I think the most economical way is to turn over the ground several times during the winter; by so doing the soil is thoroughly sweetened and the insects are more effectually destroyed, for if you only rough the ground up in autumn and leave it alone until spring the insect grubs know by instinct where they will be safe from harm, either by frost or birds, so they get into the soil deep enough to effect that purpose; but if you disturb them by bringing them to the surface you clear the ground more effectually.

In April mark out the positions for the plants, say 5 feet from row to row, and 6 feet between the plants, placing them diagonally so that each plant in one row will come half way between the plants in the next row. Dig holes about 24 inches in diameter, and as deep as the soil will allow, taking care not to turn up the hungry subsoil at the bottom. Put into each hole a couple of spadefuls of well decayed manure—if the soil is light or of a sandy nature use cow manure—thoroughly mix the manure and soil, and leave until planting time. This is how I treat mine, with the exception of the single and Pompon varieties; these I plant without manure, as I believe manuring tends to make them gross in growth, giving deformed and seed eye blooms. Pompons should be as small as possible, but have the same form and properties of the Show Dahlias. Single Dahlias also lose their charm when grown as large as we often see them. I find a slight top-dressing towards the end of August, or when the plants have nearly exhausted the soil, is all that is necessary in the way of food. As a stimulant I use soot water occasionally.

Now as to starting the tubers and preparing the plants. Some growers start their tubers as early as January, but those who only want a small collection will find the first week in March soon enough. The tubers can either be potted singly or planted several in a box. Place in a warm corner of the greenhouse, or if there is plenty of fresh manure a hotbed can be made, in fact almost any place will do to start them in, providing you can command a temperature of 50° to 60°. When the tubers have started some growers divide them and pot each piece singly, keeping only one or two eyes to each piece; others take off the shoots when about 2 inches long, with a piece of the tuber attached, and put them singly in thumb pots or four or five round the edge of a 5-inch pot, keep them close until they have rooted them, remove to cooler quarters, and grow them sturdily; after they have propagated what stock they require they throw away the old tubers. I think it is preferable to select one or two strong shoots, and rub off all the others as they come, grow these on the old tuber, and if they get root-bound before planting time give them a shift into a size larger pot, keep them

close to the glass, and as soon as weather will permit remove to a cold frame, and you will find that by the first or second week in June (which time is soon enough for planting out without protecting at night) you will have strong plants beginning to show bud in most cases, with plenty of roots to support them. They can be planted out and grown without a check, whilst plants from cuttings have to be grown in heat, which generally makes them weak and spindly, or if grown cooler they are very small at planting time in most cases, taking them until the end of July before they begin to show any sign of blooming. The Cactus varieties especially do best when grown on the old stools; such varieties as Juarezi and Charming Bride are very shy bloomers when grown from the cutting.

(To be continued.)

### IRIS LORTETI.

BLOOMS of this very distinct Iris were exhibited by Mr. C. G. Van Tubergen at the Temple Show this year, but it was not until more

FIG. 88.—IRIS LORTETI.

specimens were staged at the Drill Hall on Tuesday, June 6th, that the Floral Committee of the Royal Horticultural Society awarded a first-class certificate. From a sketch of a flower shown on the latter occasion the illustration (fig. 88) has been prepared. This portrays the size and the character of the bloom. The falls are broad, of a curious dark grey shade, covered with minute bright purplish brown spots. The standards are also large, whitish, faintly tinted with mauve, and veined rosy purple. It is a grand species, and will doubtless find its way into most collections. The flowers if not particularly showy are very quaint and interesting.

## CUCUMBERS AND MELONS AT ROWLEDGE.

THE village of Rowledge lies about two and a half miles from the famous Hop town of Farnham, in Surrey, and is situated on a high heathy common. Many years ago squatters took possession of small portions of this wild area, built huts, and in time developed into small, and perhaps poor landowners. Thus it is that now, although there is poor sandy common everywhere, there are scores of cultivated plots, and small houses dotted about. It might have naturally been thought a most unpromising spot in which a gardener should settle down and found a nursery; but that is what Mr. Mortimer did a few years ago, and if he were on the one hand daunted by the miserable barren poverty-stricken look of the soil in its unregenerate state, certainly there were about in all directions ample evidence that persistent cultivation could do wonders in the work of regeneration. Thus it has come about that a soil, presumably dear at £5 per acre, has, under trenching and manuring, become capable of sustaining fruit trees admirably, vegetables, Dahlias, Coniferae, indeed is fast becoming first-class soil, because it has, in spite of its apparent poverty, yet in it the elements of undoubted profit. Of course the nature of the external soil has little to do with the production of Cucumbers, Melons, Tomatoes, &c., under glass; but no nursery can succeed unless the ground be utilised to the utmost, and that is the case at Rowledge. The soil being sandy though shallow, it is readily pulverised, and thus is always somewhat moist. Even now, after many weeks of persistent drought, just beneath the sandy surface there is a delightful cool condition of moisture, such as could not be found in many deep retentive but still baked clay soils. After what is seen at Rowledge, no one should assume that any soil, however hungry it may seem, is too poor for cultivation. Could some of the waste millions of gallons of sewage poured into the Thames from London be utilised on these sandy heaths, the ground might soon be converted from barrenness into a condition of high fertility.

Mr. Mortimer makes the production of Cucumbers and Melons for seed purposes a great speciality, and his many famous varieties of the former, certainly some of the best in the kingdom, speak volumes for his skill as a raiser. Tomatoes are also very largely grown, but chiefly for market fruit purposes. In a long span-roof house is a batch of a seedling Cucumber the product of a cross between Telegraph and Matchless. This occupies about 50 feet run on one side only. Seed was sown early in January. The plants are some 5 feet in height, carrying on the wires two stems only. Every fruiting shoot is rigidly pinched just beyond the fruit. This batch has many grand fruits, now from 22 to 24 inches long, almost ripening, whilst others are coming on in rapid succession. The fruits all show the true Telegraph form, but are much darker and handsomer. In the next division of 50 feet is another cross-bred variety, Telegraph  $\times$  Lockey's Perfection. This, which gives rather shorter but very handsome smooth fruits, is a profuse bearer, many fruits being borne in pairs. It should make one of the finest possible market Cucumbers. The plants are only 18 inches apart, growing on a bed formed from the natural soil, slightly hollowed to a trough form, 30 inches wide, and some 8 to 9 inches deep. All along the entire length of the other side of the house are grand plants of Stephanotis. There are four of these growing in beds 3 feet square. Each one covers a length 25 feet by 6 feet of roof, blooming profusely, and growing luxuriantly. It seems an odd combination this of Stephanotis and Cucumbers, but it answers well.

In a second similar span house the entire first half is full of similar plants of Success, as originally named, or now by the Messrs. Sutton and Sons named Peerless. These plants were put out the second week in March, are now some 5 feet in height, having splendid leafage, and are fruiting profusely. The stock is remarkably true to character. The second half has more of the same Cucumber, and then all one side and one-half the other is filled with twenty-five sorts of Melons in pairs. Seed of these was sown early in March. All are restricted to one stem, and are planted like the Cucumbers 18 inches apart. The plants are now from 5 feet to 6 feet in height, and fruiting freely. The trial, which is being conducted solely for an eminent seed firm, should prove to be of exceeding interest. In this house cuttings of Fuchsias, of which many thousands are annually raised for sending out in small plants, are rooted with great success in pure common sand alone, placed in boxes, each box holding eighty cuttings. In this they make strong roots, and lift from it most readily. In another house there are growing Perfection, Plentiful, Conqueror, Maincrop, and other Tomatoes, plants about 4 feet in height, planted in 2½-foot beds, and 18 inches apart. All of them are fruiting heavily. Mr. Mortimer does not take great pains to fertilise the flowers. He finds every purpose answered by giving the sticks supporting the plants occasional sharp raps, which suffice to liberate the pollen. In this house there are large numbers of small bush Fuchsias in 48-pots to give cuttings for stock. Some of these have been in the pots for four years. They get an annual top-dressing of fresh soil.

Another house of 60 feet is devoted to Melons grown precisely as before mentioned. As this is a span-roof and the plants are heavily fruiting it will present a remarkably fine sight a little later. The varieties are Hero of Lockinge and Express. These are planted in wooden troughs 20 inches broad and 7 inches deep, with open bottoms, practically resting on the two flow pipes on each side. Then comes a long 100 feet house full again of Tomatoes Magnum Bonum, Conqueror, Earliest of All, &c., yet another same length of Melons Hero of Lockinge, Sutton's Al, Golden Perfection, Empress, and others. These are in shallow wooden troughs as before, the plants some 6 to 7 feet in

height, and fruiting heavily. Seed was sown first week in January, moving badly at first, were planted out the middle of February, no water allowed to come within 3 inches of the stems. The general appearance of the plants is superb. Occasional dressings of Thomson's Vine manure, and regular waterings with clear weak soot water are given. Other houses are devoted to Dahlias, of which a large stock of all the best sorts is grown, and Zonal Pelargoniums, ordinary flowering plants, a few Vines, and Peaches. Everything is well done, the seed specialties particularly so. Seed of the beautiful *Nemesia Strumosa Suttoni* sown in boxes in one of the houses were germinating at the time of my visit. This will be planted out to give seed stock for the Reading firm only. This annual grew most luxuriantly here last year.

In the grounds I saw numerous good bushes of Whinham's Industry Gooseberry growing and fruiting most abundantly. Mr. Mortimer is most favourable to it, not only because of its neat habit and free precocious fruiting, but also because so hardy. That is a special attribute of the highest importance to an early Gooseberry.—D.

ORNITHOLOGY IN RELATION TO AGRICULTURE.  
AND HORTICULTURE.\*

THE subject of agricultural and horticultural economics, considered in the relations of birds and insects to the produce of the soil, is one which, till recent years, has been singularly neglected in this country. In France, Belgium, and especially in America, as well as in other civilised countries, the most careful and practical investigations, under the assistance of the State, have led to the accumulation and diffusion of much valuable information on this and kindred subjects. In England, the researches of Miss Eleanor A. Ormerod are recognised as of great value in enabling the farmer and gardener to detect the various insect pests which take tithe of his crops, and in teaching him how best to apply suitable remedies for their prevention or extirpation.

Mr. John Watson has brought together a series of useful papers and notes by various naturalists, whose names are a sufficient guarantee of the high practical value of the opinions expressed, in connection with ornithology in its bearings on agriculture and horticulture. The book is divided into twelve chapters, under the various headings of Hawks and Falcons, Owls, Wood Pigeon, Rook, Starling, Miscellaneous Small Birds, Game Birds, and an appendix, with notes and additions. No less than five chapters are devoted to the sparrow, those "rats of the air," "ruffians in feathers," whose mischievous and destructive character are recognised and acknowledged by farmers and gardeners over half the world.

The larger birds of prey, buzzards, kites, goshawks, harriers, and the noble peregrine are now virtually extirpated in England, and the smaller hawks and falcons, and also owls, are far less numerous than formerly. There are at present large districts in England where you may wander all day without seeing a single bird of prey. This has been brought about by the excessive rage for game-preserving. As a class, game-keepers, considering the great opportunities at their disposal, are proverbially ignorant of natural history, and seem quite incapable or unwilling to discriminate, even from their own narrow standpoint, between the good and the bad. The natural result, therefore, of so much misplaced zeal has been an enormous increase in wood pigeons, sparrows, rats, and mice, which, now that their natural enemies, the birds of prey and weasels, have been destroyed, flourish and multiply unchecked, and yearly destroy great quantities of valuable cereals and other farm and garden produce.

In the five chapters relating to the sparrow, the evidence for the prosecution greatly outweighs that for the defence. It is clearly shown that the depredations of this pest on fruit tree buds, to fruit farmers, florists, young crops of vegetables, and more especially to corn in autumn, is enormous, and far in excess of any benefits conferred by the consumption of injurious seeds and noxious insects. They entail also direct harmful consequences by their pugnacious and self-assertive nature in driving off useful insectivorous birds from the neighbourhood of their haunts. Yet it is by no means clearly proved that an utter and complete extermination of the sparrow nuisance would be a benefit, for when man upsets the balance of nature, he very often has to pay for it in some form or other.

The sparrow certainly requires no Act of Parliament to protect him, and the plea of sentimentalists and humanitarians that he should be allowed to increase and multiply unchecked, will certainly never be listened to by those country folk who are best able to form a judgment in the matter.

There can be no doubt that, during the last half century, the wood-pigeon or ringdove (*Columba palumbus*) has increased to an enormous extent. The causes of this increase are, doubtless, the killing off of the falcons and hawks, which are the natural enemies of the race, the increase of woods and plantations, especially those of Fir, and the abundance of winter food in Turnips and other green crops. It is quite certain, too, that in the autumn the ranks of our local birds are greatly increased by immigrants from the Continent. In the autumn wood pigeons congregate and attack the ripening corn, particularly in those spots where it is storm-laid, devouring great quantities, and crushing and trampling the heads to near the ground, so that in a wet season much becomes hopelessly sprouted. In winter they commit serious ravages in the Turnip crops by eating the leaves, thus exposing the bulb to frost. They are also very partial to the young Clover plant. The

\* Ornithology in Relation to Agriculture and Horticulture. By various writers. Edited by John Watson, F.L.S., &c. London: W. H. Allen & Co., 1893.

ringdove, however, has redeeming points, its plaintive coo, roo, coo, coo, is a pleasant sound at early morning in spring woodlands, and in the winter it is a real sporting bird, and excellent eating.

The injury done by rooks has often been much exaggerated by farmers and others. If we put aside those periods of the year when it levies contributions on the newly sown corn, especially when badly covered, the time when the corn is ripening, injury done to stacks and Swede Turnips in severe weather—we have pretty well enumerated all the charges brought against him. All the rest of the year he is ridding the pastures of injurious grubs, such as the larvæ of the cockchafer (*Melolontha*), and of the crane-fly (*Tipula*). In recent years rooks, in those districts where they are too many, or short of food in a drought, have been accused of developing egg-stealing propensities, and harrying the nests of game birds and wild fowl, and killing the young, and we are afraid he is not altogether guiltless in this respect.

The starling, considered from an agricultural point, is the greatest possible friend both of farmer and gardener, its food during the whole of the year consisting of grubs, small molluscs, worms, and insects, and only very occasionally fruit and berries. In the autumn immense flights of migrating starlings come to us from the Continent; these are an Eastern race, distinct from our common bird, and have purple heads and green ear coverts, and they leave the country in the spring.

In conclusion, to sum up the evidence both for and against, as placed before us by the able ornithologists in Mr. Watson's book, it is abundantly apparent that the case for the prosecution falls very far short of the defence, and that the verdict must be an acquittal for the birds, both as regarding individual species and in the aggregate, with an admission that the benefit they confer upon man is far in excess of the injury. There is one exception to this, and that is the ubiquitous and all-devouring sparrow.

"O wretched set of sparrows, one and all."

Perhaps no greater mischief is done than by that large class of sentimental writers who are ever ready to exaggerate the good qualities of their feathered favourites and to minimise the evil. It must, however, be apparent to the dullest intellect that no wild bird is able to draw a line between the natural production of the soil and those seeds and fruit which are the results of man's industry.—JOHN CORDEAUX (in *Natural Science*).

#### PANSY SHOW AT THE MOSELEY BOTANICAL GARDENS, BIRMINGHAM.—JUNE 6TH AND 7TH.

THE Exhibition of these flowers on the above date, although not a large one, brought out a number of very fine new varieties, and these were well arranged in the handsome library of the College. For forty-eight blooms, open to all, Messrs. Pope & Sons, Kings Norton Nurseries, Birmingham, was first with a stand of good flowers, Tom Travis, Henry Eckford, Mrs. Mark, Miss Hudson, James Campbell, George Anderson, and Kate McArthur especially good blooms. There was no other competitor in this class.

In the class for twenty-four blooms of Fancy Pansies, open, Mr. Irvine, florist, Tighnabruach, N.B., was first with grand blooms of Arthur Eaton, Mrs. M. Cuthbertson, Mrs. James Brown, Tom Travis, John Knox, Miss Cullens, Mrs. T. Ritchie, Dr. Bostock, and others. Messrs. Pope & Sons, King's Norton Nurseries, were second, and in this stand were excellent blooms of John Morris, a rich coloured bright seedling of great merit; David Rennie, Henry Eckford, Tom Travis, and Mrs. Hugh Weir. Messrs. Kimberley & Son, Stoke Nursery, Coventry, were third; and Mr. T. M. Eglington, Birchfields, Birmingham, fourth. For eighteen blooms, open, Mr. Irvine was first; Mr. A. C. Christie, Shifnal, second; Messrs. Pope & Sons, third; and Mr. Wm. Fletcher, Shifnal, fourth. In the open class for twelve seedling Pansies Mr. Irvine was first, and some of them were very fine. Messrs. Pope & Sons second, and their seedling John Morris was good in this stand. Mr. A. C. Christie was third. In the classes respectively for eighteen and twelve bunches of Violas Mr. W. H. Gabb, Small Heath, was first, amongst his varieties being Annie King, Lady Amory, Bridesmaid, Master of Arts, very fine; Spotted Gem, William Neil, Gipsy Queen, Mrs. Charles Turner, Sir Joseph Terry, Duchess of Albany, Dorothy Tennant, Dean's Golden Gem, Mrs. Wm. Frater, Dean's May Queen, and Duchess of Fife.

Mr. J. Egginton, Wolverhampton, sent (not for competition) a fine display, including a superb bloom of James Swan, and fine blooms of George Henderson, J. D. Irvine, Lord Hamilton, and Mr. T. Crosby. Mr. Wm. Sydenham, Tamworth, also contributed a very fine display of Fancy Pansies, for which a first-class certificate was awarded. Amongst these Arthur Eaton, Tamworth Curate, John Lamont, Tamworth Yellow, Rev. C. Gressly, Mrs. C. L. Carnegie, Mrs. J. D. Crookstone, John Allen, Mrs. W. Frater, Emmie Stuart, James Campbell, Victory, and Dr. Harrison were very fine.

Mr. Andrew Irvine, Florist, Tighnabruach, N.B., contributed some very grand seedling Fancies for exhibition, but as there were not the required three blooms of each only three first-class certificates were awarded to his new varieties—viz., Mrs. Spence, a grand white self with superb blotch, an extra fine flower; to English Yellow, a medium sized, very refined flower of exquisite quality, golden yellow with perfect blotch; and to John Black, a grand bronzy crimson self of large size and the finest quality. First-class certificates were also awarded to Mr. T. D. Stuart, Malone, Belfast, for Emmie Stuart, a grand rosy pink-tinted flower, distinct and of the finest quality; and to H. W. Clark, rich golden yellow with superb blotch and dark top petals and very fine. A

first-class certificate was also awarded to Mr. J. Smellie, Florist, Busby, Glasgow, for Mrs. Wm. Watson, an improved Mrs. John Downie.

Mr. Irvine had some more splendid seedlings, amongst them Dora Dean (Stuart), a flower of the finest quality; Nellie Gabb, a beautiful yellow with clean blotch, which is continued in the upper petals; Mrs. Sherrard, carmine tinted flower; Maggie Lockhead, light flower with large blotch; Mr. R. Stark, very bright; Mrs. T. Morton, fine; William Hill, a grand rich flower of great substance, and extra fine; Mrs. Herbert, of Archie Buchanan style, but finer, with shoulders high and close; Annie Hill, a rich flower with superb blotch, and of the finest form; and C. H. Herbert, a very distinct rich coloured flower and extra fine; Mr. E. D. Martin, white tinted with lilac and large blotch.

Mr. I. D. Stuart, Belfast, sent several blooms each of some beautiful seedling Violas, many of them being so distinct and of such fine quality that first-class certificates were awarded to Carissima, veined rosy lilac and white; Erin, a very fine rich violet, striped and clouded flower; Diva, snow white, and entirely rayless, small flowers; Hibernia, rich purple striped, distinct and fine form; Commodore, pale blue lavender, a most pleasing shade of colour, and an acquisition; Mary Stuart, white of fine form, and entirely rayless; Mrs. Joseph Chamberlain, suffused rose and lilac; Con. O'Neil, white striped with rich violet purple, very bright; Lady Dufferin, white, clouded and striped with lilac; Lovelight, white, with a Picotee edging of lavender. Mr. Stuart has evidently a fine strain of seedling Violas, and he is equally fortunate in seedling Fancy Pansies, being the raiser of some of the fine seedlings shown by Mr. Irvine, and such flowers as Mrs. T. D. Stuart, Emmeline, and many others.

A tray of very fine Mushrooms grown under the arches on which the college is built was shown by Mr. Ross.

#### EARL'S COURT ROSE SHOW.

JUNE 14TH AND 15TH.

A SUPPLEMENTARY Show of Roses was held at the Gardening and Forestry Exhibition, Earl's Court, on the above dates. This was practically the first Rose Show of the season, and notwithstanding the prolonged drought the blooms staged were of first-rate quality. Both the open and amateurs' classes were well filled, and in some instances the competition was very keen.

In the class for thirty-six Roses, distinct, single trusses, Mr. B. R. Cant, Colchester, secured the leading prize. The blooms were very fine and freshly coloured. The best of the varieties shown included Gustave Piganeau, A. K. Williams, La Havre, Madame Gabriel Luizet, Prince of Wales, Horace Vernet, and Sultan of Zanzibar. Mr. Frank Cant, Colchester, was a close second, the blooms in this stand being perhaps a little smaller, but of excellent form. Grace Darling, J. D. Pawle, Prince Arthur, A. K. Williams, and Etienne Levet were very good in this contribution. Messrs. G. Paul & Son, Old Nurseries, Cheshunt, were third with flowers that would in some instances have taken a premier position.

For twenty-four, distinct, single trusses, Messrs. D. Prior & Son, Myland Nurseries, Colchester, were awarded the first prize. The flowers were fresh and well coloured, especially Victor Hugo, Gustave Piganeau, Annie Wood, and Abel Carrière. Mr. G. Mount, The Nurseries, Canterbury, was second with excellent flowers; the third prize going to Messrs. G. Cooling & Sons, Bath, for a stand of fresh blooms. The competition in this class was very close, there being no less than eight exhibitors.

In the class for twenty-four Roses, distinct, three trusses of each, there were six competitors, including some of the leading growers in the country. Mr. B. R. Cant, however, proved the winner after a keen contest, staging flowers of medium size, but remarkable for their colour. Mr. F. Cant was a close second. The third prize went to Messrs. D. Prior and Son, Bath.

The Tea and Noisette Roses were very fine. In the class for eighteen varieties, three trusses of each, Messrs. D. Prior & Sons, Colchester, were awarded the first prize. The best blooms in this stand were Catherine Mermet, Marie Van Houtte, Madame Lambard, Jean Ducher, Innocente Pirola, and Ernest Metz. Mr. Frank Cant was second with a stand of neat blooms, the third prize going to Mr. George Prince, Oxford. The latter's stand included some grand blooms of Princess of Wales. Mr. B. R. Cant was awarded an extra prize in this class. Messrs. D. Prior and Sons were also first with eighteen Teas and Noisettes, distinct, single trusses. The flowers were excellent, the best being Catherine Mermet, Adam, Rubens, Marie Van Houtte, and Jean Ducher. Mr. G. Prince was a good second, the third prize going to Mr. J. Bradbury, gardener to S. P. Budd, Esq., 8, Gray Street, Bath.

In the amateurs' class for twelve trusses of any Teas or Noisettes C. J. Grahame, Esq., Coombe Road, Croydon, was awarded first prize, showing neat blooms of Hon. Edith Gifford. A. H. Gray, Esq., Beaulieu, Newbridge, Bath, was second with well coloured Maréchal Niel, Mr. J. Bradbury being third. R. L. Knight, Esq., Bobbing, Sittingbourne, was awarded first prize for twelve Teas or Noisettes. This stand comprised Souvenir d'Elise Vardon, Ernest Metz, Maréchal Niel, Comtesse de Nadaillac, Catherine Mermet, Scipion Cochet, Madame Cusin, Hon. Edith Gifford, The Bride, Jules Finger, Anna Ollivier, and Souvenir de Paul Neyron. Mr. J. Bradbury was second; and Mr. Mease, gardener to A. Tate, Esq., Downside, Leatherhead, third. For twelve trusses of any Tea or Noisette (open) Messrs. D. Prior & Sons were first with fine blooms of Marie Van Houtte; Mr. Frank Cant was second with a box of Hon. Edith Gifford; and A. H. Gray, Esq., being third with Maréchal Niel.

Mr. B. R. Cant was awarded the premier prize for twelve blooms of any light Hybrid Perpetual, showing a splendid stand of Madame Gabriel Luizet. Messrs. D. Prior & Sons were second with La France, and Mr. C. Turner, Royal Nurseries, Slough, third, with Madame Gabriel Luizet. Mr. Frank Cant secured the leading position for twelve dark Hybrid Perpetuals, showing splendidly coloured Horace Vernet. Mr. C. Turner was second with Marie Baumann, and Mr. B. R. Cant third with A. K. Williams. Mr. W. Mease was first for twelve bunches of garden Roses, the Rev. J. H. Pemberton, Havering-atte-Bower, Essex, being second.

In the amateurs' class for twelve Roses in distinct varieties, three trusses of each, Mr. J. Bradbury, gardener to S. P. Budd, Esq., Gay Street, Bath, was awarded the first prize. The varieties staged were Gabriel Luizet, Madame Cusin, Princess of Wales (good), A. K. Williams, Caroline Kuster, Prince Arthur, Edith Gifford, Comtesse de Nadaillac, The Bride, Mons. Noman, Innocente Pirola (good), and Alfred Colomb. J. Gurney Fowler, Esq., Woodford, Essex, was second with a creditable exhibit; and Mr. Mease, gardener to A. Tate, Esq., Downside, Leatherhead, third.

For twelve Roses in distinct varieties, one bloom of each, C. J. Grahame, Esq., Coombe Road, Croydon, was first, staging fine examples of La France, Victor Hugo, Madame Gabriel Luizet, Dupuy Jamain, Innocente Pirola, Gustave Piganeau, Viscountess Folkestone, Xavier Olibo, Edith Gifford, Souvenir de S. A. Prince, and Mrs. John Laing. J. Gurney Fowler, Esq., was second; and Mr. J. Bateman, Rosevale, Archway Road, Highgate, third.

For twenty-four blooms in distinct varieties, the Rev. J. H. Pemberton, Havering-atte-Bower, Essex, was awarded the first prize for an excellent exhibit. His stand comprised La France, Duchess of Bedford, Maid of the Mist, A. K. Williams, Caroline Destout, Gustave Piganeau, Marchioness of Dufferin, Victor Hugo, Etoile de Lyon, Etienne Levet, The Bride, Marie Baumann, Duchess of Albany, Horace Vernet, Jeannie Dickson, Comte Raimbaud, Mons. E. Y. Teas, Comtesse de Nadaillac, Lady Mary Fitzwilliam, Lady Helen Stewart, Jean Ducher, Charles Darwin, Mrs. James Wilson, and Exposition de Brie. Mr. Bradbury was awarded the second, and R. L. Knight, Esq., Bobbing, Sittingbourne, third. There were six competitors in this class. In the class for twelve blooms of any Hybrid Perpetual, J. Gurney Fowler, Esq., was first with Mrs. John Laing; A. H. Gray Esq., Beaulieu, Newbridge, Bath, second with Madame Gabriel Luizet; and Mr. J. Bradbury third with the same variety.

Mr. Chas. Turner, Royal Nurseries, Slough, was awarded first prize in the class for twelve bunches of garden Roses, including, amongst others, Turner's Crimson Rambler, Boule de Neige, Lamarque, and W. A. Richardson. Messrs. G. Paul & Son, Old Nurseries, Cheshunt, were awarded the second prize, and Messrs. G. Cooling & Son, nurserymen, Bath, the third.

Miscellaneous exhibits were numerous and of a varied character. Messrs. Wm. Paul & Son, Waltham Cross, arranged a charming group of cut and pot Roses, prominent amongst which were Corinna, Duke of York, Marie Van Houtte, Antoine Ducher, Blanche Moreau (Moss), Hon. Edith Gifford, L'Ideale, and Madame P. Perny. An extra prize was awarded for this grand contribution, which was one of the finest collections of cut Roses we have seen. Messrs. D. Prior and Son staged a beautiful stand of Rose Wm. Allen Richardson "not for competition," and Messrs. G. Cooling & Son two boxes of old-fashioned garden Roses.

Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, staged some grand hardy flowers, including Gaillardias, Poppies, Spiræas, Ixias, Delphiniums, and Lilium Poulentia (certificate). Messrs. P. Barr & Son, King Street, Covent Garden, staged two fine groups of hardy flowers. Prominent amongst others in these exhibits were Delphiniums, Gladioli, Irises, Liliums, Iceland Poppies, Ixias, and Centaureas. Mr. H. B. May, Dyson's Lane Nurseries, Upper Edmonton, arranged a very fine group of plants, including Palms, Clematises, Spiræas, Hydrangeas, Begonias, Aspidistras, and Irises. Mr. H. J. Jones, Ryecroft Nursery, Lewisham, S.E., exhibited a collection of Fancy and Show Pelargoniums. This was a very fine exhibit, the group including, amongst others, Jules Ferry, Eclipse, Sir Trevor Lawrence, President Harrison, Rose Queen, Countess, Princess May, Tommy Dodd, and Decorator. The same exhibitor also staged a basket of his fine Ivy-leaf Pelargonium Ryecroft Surprise, for which a certificate was adjudged.

Mr. W. Rumsey, Joyning's Nursery, Waltham Cross, sent six boxes of cut Roses not for competition, including Tea and other varieties. Messrs. H. Cannell & Son, Swanley, sent a fine collection of cut Begonias, and the blooms being staged in bunches attracted some attention. Messrs. J. Cheal & Sons, Crawley, had hardy flowers, Roses, and Violas in variety, as also did Mr. E. F. Such, Maidenhead. Mrs. M. Hodgkins, Didsbury, arranged a table of skeletonised leaves of flowers. Extra prizes were awarded to the foregoing, also to Miss M. Walton for table decorations.

Mr. S. Mortimer, Rowledge, Farnham, staged a large collection of Tomatoes, Cucumbers, and Melons. Some of the latter were of splendid flavour, the best being Duke of York, green fleshed, rich and juicy; Miss Etell, green flesh, fine flavour, and Isinglass, a grand scarlet fleshed variety of first-rate quality. There are new seedling varieties and will doubtless be heard of in the future. A silver-gilt medal was awarded for Mr. Mortimer's contribution. Mr. T. Hardy, Ash House, Parson's Green, S.W., staged some very fine Mushrooms, which had been grown outdoors on the ridge system. A silver medal was awarded for this exhibit.

#### HARDY FRUIT GARDEN.

**Summer Pruning Young Fruit Trees.**—Whatever the age of fruit trees there is generally some necessity during the growing season to curb excessive growth in order to equalise the vigour and prevent its accumulation in a few specially favoured parts. It is also essential that superfluous shoots should be early dispensed with, that they may not become robbers of sap to an undue extent. The judicious suppression of weak, crowded, misplaced and gross wood will render the training of trees in the desired forms much easier of accomplishment, as well as concentrate the vigour in the special parts needing it, with a view to a proper balance of growth and productiveness in the future.

**Maiden Trees.**—Laterals sometimes form in the axils of the principal leaves and extend. When such appear they should be cut back to one leaf, further extension subsequently also being restricted to one leaf. The stock on which the leading growth was worked ought especially to be kept clear of superfluous growths. Latent buds may push growth sometimes during the season. Remove them promptly. No shortening of the stem or leader should be done during the summer.

**Pyramids.**—Stop the side shoots on the main branches to four leaves, and subsequent growths from them to one leaf. The upright leader and the extremities of the chief branches may be topped when a foot or more long. The branches must be sufficiently far apart to permit the sun's rays to reach the leaves. Overcrowding of the growths in summer is inimical to productiveness.

**Bush Trees.**—The main object with these is to keep the growths thin. Summer prune as above advised, but do not cut back short-jointed shoots that may be developing a fruiting bud at the point. Open bush trees are generally allowed more freedom. Thin crowded shoots; any crossing or interfering with adjoining growths are better cut out entirely. Their removal will improve the shape of the trees, and the admission of sun and air to the centres of the bushes will be better effected to the permanent advantage of foliage, wood, and fruit.

**Horizontally-trained Trees.**—Two-year-old trees producing side shoots on the main stems may have these shortened back to four leaves when the latter have attained full size. Sub-laterals forming afterwards pinch to one leaf. Shoots originating from latent buds on the upright central stem may, if well placed, also be pinched and closely shortened in autumn for forming spurs. Avoid retaining too many. The extension of the leaders will be accelerated by pinching the side shoots, sometimes causing the leader of the central stem to grow rapidly. The opportunity may then be embraced of pinching it at a point where a fresh pair of side stems are to be originated. Two pairs are thus easily secured in one season.

**Cordon Trees.**—The side growths originating on the lower parts of young trees, trained either upright, horizontally, or obliquely, must be shortened to the fourth good leaf. The leading growths seldom need shortening, but the exceptionally vigorous may have their points pinched when the growths exceed 15 inches, or they may be depressed. This arrests vigorous growth, and concentrates the sap in the lower buds. It also assists the development of side growths, which having produced six good leaves are pinched to four for the production of fruiting spurs.

**Standard Trees.**—This form of tree in the course of formation requires a certain amount of summer pruning. When the stem has to be formed from a maiden tree side shoots are allowed to form on the single upright shoot as it extends. Their presence adds materially to the thickening of the stem if they are summer pruned similar to other growths. In winter they are cut clean away. After the required height of the future stem has been reached the growth above that point must be allowed to develop half a dozen full sized leaves, and then be suppressed by pinching above that number. Lateral shoots will certainly push, to be cut back in winter for the formation of main branches the following year.

**Propagating Strawberries for Forcing.**—Strawberries for pot culture and forcing purposes require to be propagated early, the present month being the best time. Select runners from strong plants which have during the season given indications that they are not barren. As the plantlets become large enough peg the first and strongest produced on the surface of good loamy soil, firmly compressed in 3-inch pots placed in convenient positions. Afford water to maintain the soil moist and to encourage rooting. When this is well accomplished detach the runners from the parent plants, and set the pots on a moist base of coal ashes in a sunny position, where they will soon fill the pots with roots ready for transference to 5 and 6-inch pots for fruiting.

**General Work.**—Continue to thin fruit where the crops are heavy. Make constant warfare with insects. Assist old-established or feeble trees with liquid manure. The roots will appropriate a considerable quantity if the soil be moist with positive benefit. Wall trees frequently suffer from lack of moisture in the soil. Dry seasons cause excessive evaporation from the foliage, which then makes extra demands upon the roots, the latter upon the food stores in the soil. Any deficiency is then felt throughout the tree's system, and pests of various

kinds take the earliest opportunity of establishing themselves. If more attention were given to the roots of trees there would be better crops, cleaner growths, and a comparative immunity from diseases.

### FRUIT FORCING.

**Peaches and Nectarines.**—*Earliest Houses.*—When the fruit is gathered admit all the air possible day and night unless the weather be exceptionally cold, when modify the ventilation. If the roof lights are moveable take them off about a month after the trees have been cleared of fruit and had full ventilation for at least a fortnight. Where red spider or brown scale has obtained a footing eradicate the pests promptly, red spider, by syringing with a solution of softsoap 2 ozs. to a gallon of water, applying it forcibly so as to destroy their webs. For the scale dissolve half a pound of softsoap in a gallon of boiling water, adding half an ounce of washing soda and a wineglassful of petroleum, and either churn with a force pump or place in a 2-gallon stone bottle, cork, and agitate violently for five minutes, then add enough hot water to make 4 gallons, mixing thoroughly. When cooled to 90° to 100° apply with a fine-rose syringe, or an apparatus with a spraying nozzle, keeping the mixture well stirred while it is being applied. In each case repeat at intervals of a few days, washing with clean water at least once between the applications. Cut away the wood which has borne fruit to the shoot at the base intended to fruit next year unless the wood is required for extension. Remove all superfluous shoots, and keep laterals closely stopped. The borders should be well watered, affording liquid manure to weakly trees.

*Houses of Ripening Fruit.*—Cease syringing trees with the fruit ripening, but provide moisture by damping until the fruit is ripe; even when ripe an arid atmosphere must be avoided. Supply water at the roots liberally. Great care is necessary in gathering Peaches, as the least pressure makes a mark and spoils their appearance. A piece of wadding may be held in the hand, and the fruit removed with gentle pressure, but experts take the fruit in the ball of the hand and bring to the fingers to act evenly on the base, and so remove it gently. Peaches and Nectarines keep best in a sweet, cool, and airy fruit room after they are gathered.

*Trees Swelling their Crops.*—When the stoning has been completed the trees will bear strong heat without fear of the fruit falling. Trees carrying full crops should be supplied with nourishing food, either as top-dressings that act quickly, as dissolved bones and powdered saltpetre, say five parts superphosphate and three parts nitrate of potash, with one part sulphate of lime, mixed, using a quarter of a pound per square yard after the soil has been made moist, and after applying the manure wash it in moderately. House sewage is excellent if it is properly diluted, also stable and cow house drainings diluted with at least five parts of water. Red spider must be kept down by syringing twice a day in fine weather. Ventilate early, keep through the day at 70° to 75° artificially, and 80° to 85° with sun heat, and close sufficiently early to increase to 90°. This, with plenty of moisture in the house, will insure large fruit, and if ventilation be given before nightfall no disaster will arise, provided more air is admitted sufficiently early in the morning to allow the foliage and fruit to warm equally with the atmosphere. Keep the fruit with its apex to the light, laths across the trellis will admit of this being done perfectly.

When the fruit approaches ripening cease syringing, admit air freely, and maintain a night temperature of 60° to 65°, that being sufficient in the daytime when dull. If the sun be very powerful, a slight shade over the fruits commenced to ripen will prevent their being ripened too quickly at the apex, whilst the base remains quite hard. Paper shades over the individual fruits are best. If it is wished to accelerate the ripening the temperature should range 70° to 75° by day, and 10° rise from sun heat.

*Fruit Stoning.*—During this important stage it is necessary to avoid a close atmosphere, and to keep as uniform a condition of temperature and moisture as possible. Maintain a steady temperature of 60° to 65° at night and on cold dull days, 5° to 10° advance with a little sun, and the usual still further rise of 5° to 10° at closing time from sun heat. Avoid sudden fluctuations of temperature and cold draughts, and keep the soil in a duly moist but not saturated condition. Do not permit fruits to stone that must be removed afterwards, but reduce the number in good time. Pinch gross growths or remove them altogether, and aim at an equal distribution of growth and vigour throughout each individual tree.

*Succession and Late Houses.*—Thin the fruits to a few more than will be required for the crop, retaining the most perfect in shape, largest, and best placed, allowing about a fruit to each square foot of trellis covered by the trees. Train the wood thinly, reserving a shoot at the base of the current fruiting branch, stopping the growths on a level with or above the fruit at two or three leaves. Side growths on extensions not required for furnishing the trees may be stopped at two or three leaves to form spurs. These spurs usually set and swell fruit when the strong growths on young trees do not. Syringe twice a day in fine weather, but on dull days damping will be sufficient, with an occasional forcible syringing to keep down red spider. Inside borders will require water at weekly or fortnightly intervals, according to their proportions, supplying liquid manure to weakly trees. A light mulch of lumpy manure will keep the soil more uniformly moist, and encourage surface roots without excluding air.

**Melons.**—Every available house, pit, or frame will now be utilised, or they should be at once to afford a supply of fruit in late August or September. Plants that were raised some time ago should be placed out, and they will make growth rapidly and set their fruit with very

little trouble. Where there are no plants and frames are at liberty, a last sowing should be made for growing in manure-heated pits or frames. It is advisable to make the beds at once, or at the same time the seed is sown. Sow the seed in 4-inch pots half filled with soil, placing one or two seeds in each, with a pane of glass over the pot. Remove the glass when the plants appear, and place a little soil around the stems. When the bed is ready put one plant in the centre of each light, planting within half an inch of the seed leaves, with the soil inclining from the stem, firming the soil well, give a good watering, and shade from bright sun. Pinch out the point of the leader at the second rough leaf, which will induce side shoots; reduce these to four, take two to the front and two to the back of the frame, rubbing off all the laterals to within 4 or 6 inches of the stem all round, and every other lateral upon the primary shoots, stopping these about 9 inches from the sides of the frame.

**Cucumbers.**—When the night temperature can be kept from falling below 65° fire heat may be dispensed with, much being effected by husbanding the sun heat and closing early. Continue to look over the plants twice a week, well thinning the old growths, and train young in their place. Avoid overcrowding and overcropping, and remove the fruit when fit to cut. Supply liquid manure copiously twice a week, and surface dress with lumpy loam occasionally. Sprinkle the bed occasionally with horse droppings, but be careful not to overdo it, or the foliage will suffer irreparable injury. Syringe on clear days in the afternoon only, but keep a good moisture in the house all day long by damping surfaces as they become dry. Morning syringing is often the cause of much injury, and if practised at all it should be done early and lightly. Promptly shade on bright weather succeeding a dull period, but at other times only to prevent flagging. Ventilate early, but avoid draughts, and never admit air to lower the temperature. Keep through the day at 75° to 90° as the force of the solar heat dictates, but in bright weather between 80° and 90° should prevail in the house from 8 A.M. to 6 P.M. Close early so as to increase to 90°-100°, and admit a little air before nightfall as a safeguard against condensed moisture, and increase the ventilation from seven to eight o'clock on sunny mornings.

*Pits and Frames.*—Unless the weather prove cold night coverings will not be necessary; if put on it must not be until the sun is off the lights, and it should be withdrawn early in the morning. Commence ventilating at 75°, and increase with the sun's advance, keeping through the day 80° to 90°, closing at 3 to 4 P.M., then sprinkle the foliage, and after being closed for an hour or two admit a little air at the back of the lights to allow of any pent-up moisture escaping. Water will be required about twice a week, and weak tepid liquid manure may be given occasionally, keeping it from the foliage and fruit. Attend to the plants once a week, stopping the growths about one or two joints beyond the fruit, removing bad leaves and exhausted growths. If the plants show signs of exhaustion top-dress with lumpy loam, and layer some of the younger shoots at a joint from which roots will be freely emitted and strengthen the succeeding growths, so that the plants will continue to produce clean fruit for a long period.

### THE FLOWER GARDEN.

**Sub-tropical Plants.**—Most flower beds and borders will be filled ere this, but the efforts at beautifying a place ought not always to be confined to these details. Instead of keeping the houses crowded with plants which very few people care to see during the summer months, some of them should be transferred to sheltered nooks. Many an interesting corner might thus be rendered attractive. Strong plants of Musas, large specimens of Latanias, Chamerops, Scaforthias, and other comparatively hardy Palms, tall Cordylines or greenhouse Dracenas, Acacias, Cyperuses, Ficus elastica, Arundo donax, and the variegated form of Caladium esculentum, Yuccas, Aloes, and such like are all more less well adapted for this purpose. Shade is not indispensable, but many of the plants like a moderate amount of it, and these may thus be grouped where flowering plants would fail. Planting out is not recommended, the better plan being to plunge the pots to the rim. Extra good plants are most effective quite by themselves plunged in the turf in some sheltered nook, the others being very thinly grouped in somewhat similar positions. The tallest of the Cordylines and Musas would be best disposed in shrubberies where they could be seen with only the upper part of their stems exposed. Most of them, if kept properly supplied with water, could be returned to the houses in the autumn before severe frosts damage them, and would then be available for the next season.

**Greenhouse Flowering Plants.**—Some of these might also be utilised for the adornment of pleasure grounds. Fuchsias invariably thrive well in the open, oftentimes after they have refused to do so under glass. If it is desirable to save the plants for another year plunge the pots to the rims in the turf. Standards are very effective as "dot plants" in beds of Begonias, while these, pyramids and bushes, may also be placed in groups on the lawn by plunging the pots. If kept well supplied with water and liquid manure they will flower grandly till the autumn. Cannas are very effective in masses, and continue flowering throughout the summer. These may either be plunged or planted out. Erythrina crista galli attracts far more attention than it does under glass. A mass is very effective either planted out in a bed or plunged in the turf. Hedychium Gardnerianum again grows very sturdily, and flowers grandly in the open; and if plunged in pots can be moved when getting shabby, and some other plants take its place. Pyramids of Ivy-leaf Pelargoniums treated similarly to Fuchsias are very effective, and the same may be said of trained Pelargoniums generally, and also Heliotropes. Large Celosias or feathered Cockscombs

plunged in the turf in July are very showy, and even the ordinary Cockscombs, turned out after they are nearly or quite fully grown, last for a long time.

**Mulching Flower Beds.**—During hot and dry weather there is every inducement for the watering pot and hose to be freely used, and this not always to the advantage of the plants. Very often a light watering applied in the evening is all that is needed, the soil though dry on the surface being quite moist enough underneath. Constantly drenching the ground with cold water greatly impoverishes it, and many plants do not thrive well under such conditions. A light surfacing of common salt, stirred in with a small Dutch hoe or a pointed stick, would make many soils more retentive of moisture, also proving a good manure when washed down to the roots, and ought to be tried. In most cases a mulching of either old Mushroom bed refuse, leaf soil, well decayed tanner's bark, fine peat, cocoa-nut fibre refuse, or even fine dry soil would conserve the moisture in the beds and obviate the necessity for watering so frequently. Especially ought Tuberous Begonias, Verbenas, Fuchsias, Violas, and Calceolarias to receive this attention. First give the beds a good watering, unless fortunately a soaking rain falls opportunely, and the next morning lightly stir and level over the surface with a flat hoe, and then apply the mulch, the whole of the bed being covered with a moderate thickness of it. This mulching may not wholly do away with the necessity for watering, and should the weather continue dry and hot the soil ought to be probed occasionally, and water given when needed.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### THE WEATHER AND BEES.

THE weather continues warm and sunny, but there is a harshness in the atmosphere which tells alike against bees and plant growth, aggravated by the myriads of garden pests. We had a fine shower at the beginning of the week, but more rain is wanted. The bees are searching for honey, but owing to the drought and paucity of flowers are not gathering it in great quantity. In a few days the Clover will be ready; then, as the hives are in good condition, they will, if the weather is suitable, work effectively. We are not the most favourably situated for keeping bees, but are well stored with honey. A few miles further up the Clyde ordinary hives in April increased in weight 40 lbs. First swarms are getting strong, so are some of the early after swarms—a great advantage near the Clover season.

#### SUPERING.

This will be the order of the day to a greater degree than we are accustomed. It must be borne in mind that bees will not take to supers till the body of the hive is fully occupied with bees, brood and food. It is of no use putting on supers till then, and honey is plentiful. When that is the case do not delay a minute. One of our old and successful plans to induce bees to enter supers was to add a nadir for several days, then take it away, and at the same time put on the super or supers, for with strong hives we usually put on two and even three at a time; then after the bees had the supers well begun either a combed division was put under again or the one recently removed. In olden times when there was no foundation the white combs made in the nadir were employed as guides to supers, or if the temporary nadir was a super it took its right place. Admittance of course was given at the sides of the hive only, and it was a rare thing to see brood in supers.

#### THE CLOSE-FITTING DIVIDER.

My contrivance was used in large frame hives. After allowing the bees full scope to the dozen frames containing twelve superficial feet of double-sided combs, one or two frames were removed, supers put on crowding the bees into them. After they had well started them the frames recently taken away were added. This manipulation was one of the best to delay or prevent swarming, but let no reader of this *Journal* believe that swarming can be absolutely prevented, for it cannot. Bees swarm because it is natural for them to do so, while they make preparations about a week or more before it takes place.

#### RETURNING SWARMS.

Do not return swarms unless they be after swarms not wanted, for assuredly they will swarm again, but transfer the supers with bees and combs from the old stock to the swarm. An answer of mine to a query was contradicted in a contemporary. It was, that when the swarm took the place of the old stock the bees of the latter would not enter the hive of the former unless it was taken a long distance away or shut up inside. In this case there would

be no bees flying to go back, while the moment a swarmed stock hive is handled the bees seem to know it, and keep up a continuous humming and fanning to draw the attention of bewildered returning bees. They then immediately mark their new site, and return to it as unerringly as they did to the old one. Of course, a theorist who writes on bees and a practical bee-keeper are as distinct from each other as are the different journals.

#### DIFFERENT SHADES OF POLLEN.

The bees are busy gathering pollen from the *Thalictrums*. It is very interesting watching them on these plants, as it is easy to see the different hues upon their legs, varying from light brimstone to dark orange from the same plant, a change probably due to the saliva of the bees being more acid in some than others.—A LANARKSHIRE BEE-KEEPER.

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Campanulate Foxglove** (*J. H. W.*).—Yes, the "freak has come under our notice before." Allusion was made to an instance in last week's issue of the *Journal of Horticulture*, page 469, to which you may with advantage refer.

**The Home of the Tomato** (*Beulah Spa*).—It is a native of South America, probably Peru, but is found wild in Mexico, Brazil, and the Southern States, also in the East Indies, whence it was supposed to be taken by the Malays. It was introduced to this country in 1596.

**Insects on Plums** (*S. H. Stott*).—Aphides are increasing rapidly on fruit trees and bushes. It is important that timely measures be taken for their eradication. Those on the Plum leaves you send are dead with the exception of one or two newly hatched, these proving the necessity of at least two applications for clearing the trees.

**Diverse Methods** (*St. Julien*).—The same end may be obtained by different routes, and similar results by differing methods, if they are pursued intelligently. Contradictions are instructive, and it is common for an apprentice to learn (if he does not already know) more than his master. We are obliged by your letter, and agree with some portions of it.

**Culture of *Fadyenia prolifera*** (*W. T. B.*).—This curious little Fern requires the temperature of an ordinary exotic fernery, or the cool end of a moist stove. It succeeds in a compost of peat and sand, with abundant drainage, a wide shallow pan being best suited for it, as the long narrow fronds can then extend freely. When the young plants are produced at the point they will soon root in the soil, and may be either separated or allowed to remain, the latter being generally preferred, as they impart a peculiar appearance to the plant. It is usually found advisable to cover the plant with a bellglass to preserve an equable temperature and moisture about it.

**Rose Cuttings Failing** (*E. C.*).—The chief cause of failure may probably be traced to keeping the cuttings, and eventually young plants, too closely covered, thus making them tender and liable to destruction by the frost, to which they appear to have been victims. When Rose cuttings are inserted in summer it is desirable to keep them close, moist, and shaded for a time, but they should be gradually inured to sun and air and be fully exposed as soon as possible in the autumn. It may be necessary to protect them in winter if the frost is severe. Thousands of Briar cuttings, also numbers of Rose cuttings, are inserted in the open ground in October, and if the right kind of wood is chosen, and the cuttings made and inserted quickly and properly, the great majority root and pass the winter with soil drawn up the stems. In gardens where only a few dozens or hundreds are put in cocoa-nut fibre refuse may be employed for protecting them. When inserted in cold frames or covered with hand-glasses they are apt to fail through being "coddled," and they should be fully exposed except during very inclement weather during the autumn and winter. You have been too kind to your cuttings, and possibly they may have been too crowded under the bell-glasses. If we knew the size of these and the number of

THE Rose has this season come earlier than usual to delight us with its beauty and fragrance, and it may seem that writing in praise of its followers is rank disloyalty. I would, however, disavow all thought of treason to this "Queen of Flowers," but would leave other pens to speak of its beauty. The proverb *ne sutor ultra crepidam* is a true one, and the many able rosarians who write in the columns of the *Journal* are more qualified to descant upon the beauty of their favourite flower than he who pens these notes. We have to devote ourselves to the humbler plants, though some of us, perhaps, in our day dreams may picture a Rose garden filled with Roses of all kinds; the old fashioned ones that have made their mark on the pages of history and which are certain to be again sought after; those that have been the origin of some quaint and beautiful legends; the rare species for which we are indebted to the indefatigable search of explorers; or, last but not least, the productions of the florist that possess a beauty which seems too perfect for the vicissitudes of this rude climate of ours in ordinary years. If, however, this garden only exists for us in our day dreams, and we are not qualified to discuss the merits and demerits of the various forms in which the Rose displays its charms, we may at least offer our respectful and admiring obeisance.

Amid the profusion of beauty which this June has adorned the garden, it is a mark of the exceeding value of the estimation in which the Rose is held that no rival can in the public mind displace it, and the many forms of floral beauty of the month have only shown its pre-eminent value. The Lily, an ancient rival, has given us the noble *L. Szovitzianum*; the bright and showy *L. davuricum*; the neat and pretty dwarf *L. elegans*, varying much in height and in shade of colour; the old *L. Martagon*; and in some gardens the chastest of all—the Madonna Lily—has delighted the observer with flowers of highest purity. Vastly inferior, yet with some merit, is the small flowered *L. pyrenaicum*, whose flowers exhale so powerful a perfume. Then could aught exceed the elegance and beauty of the many Irises or "Rainbow Flowers" which have come to give pleasure to our hearts? Bearded and beardless Flag Irises, of tall or of dwarf habit, with massive and broad or grassy leaves; Spanish or English bulbous forms, with flowers of exquisite shape, and others of a similar habit of growth, such as *I. Boissieri*, have brightened the borders and lured us to stand awhile and study the wondrous colouring which, in shades of purple, blue, yellow, white, brown, and others too numerous to detail, defies description, and laughs to scorn the attempts of the artist to transfer it to his canvas or to paper, and, in greater degree, eludes the struggle to portray its tints with the pen. Alas! that one should up to the present have to admit defeat with the *Oncocyclus* section, and that we should anew have to attempt to solve their culture—a solution only to be found apparently by trial in each garden.

If the Rose has its delightful fragrance, so, too, has the Pink, which in various forms has been one of the flowers of June, and the season has suited it perfectly, leading one to think that a few more years like this would lead to the beauty of this flower being recognised anew. Very charming have been some of these mounds of foliage covered with massive flowers of exquisite perfume, such as Mrs. Sinkins, of which an old plant with some fifty fully open

flowers has been most delightful; or others with single flowers, such as "Maiden Pinks of odour faint," or some of the rarer alpine species which have formed such pretty objects on the rockeries. How dear these old Pinks have been in days gone by may be gathered from Spenser's reference in "Amoretti"—"Her lovely eyes like Pincks but newly spread."

The Tulip has long gone to rest, but the Poppy has fallen heir to at least its brilliancy, and in many kinds has endeavoured in some degree at least, to fill its place. It is curious to see in what little estimation the Poppy is held by many, and how little its aid is sought for garden purposes. In my garden it has become fairly naturalised, and Oriental Poppies, Shirley Poppies, Iceland Poppies, Alpine Poppies, and several others come up in superabundant plenty in unexpected places. May I commend to the notice of some a word or two from Ruskin? He says:—"We usually think of the Poppy as a coarse flower, but it is the most transparent and delicate of all the blossoms of the field." I know my taste in preferring single flowers among Poppies will not be universally approved, but I submit that the single, or even the semi-double flowers are immeasurably more graceful than are those of the double varieties.

If the procession of the flowers of June has had its monarch it has also had its guardsmen, and I fancy this honour will by universal acclamation be conceded to the stately Delphiniums, which have been fitly called "princes among summer flowers." Gallant and brave they seem with their noble spikes of deep blue, light blue, or purple of varied shades, some with "dove's neck" lustre and with much variety of central eye. It is true they lack fragrance, but we do not expect our warriors to be odorous of perfume, even when on grand parade. As it is these flowers brook no rivals in their own particular sphere, even the noblest of the Monkshoods showing its inferiority in the presence of these princely Larkspurs.

A commanding place in the garden of hardy flowers must always be taken by the Campanulas, which in many forms and shades ornament the borders or form on the rockeries masses of exquisite grace. Peach-leaved, Broad-leaved, and Nettle-leaved Bellflowers in various shapes and shades seek to vie with each other in representing worthily the claims of the taller forms. *C. glomerata* in purple and in white; *C. Van Houttei*, *C. punctata*, and several others exhibit the beauty of what may be called the intermediate forms; while on the rockery *C. Portenschlagiana*, *C. garganica*, *C. G. F. Wilson*, and others in shades of purple, blue, or white testify to the incontestable right of the Bellflower to a place in the garden.

The Mulleins have also been ready to display their grace (if I may be allowed to apply this word to the beauty of the *Verbascum*), and their handsome spikes of flowers have been much admired. In my garden *V. phoeniceum* is represented in various shades and colours, perhaps the prettiest being a white one; but pretty as is this I prefer the white variety of *V. nigrum*, which is extremely handsome with its long spikes of white flowers with purple centre. A strange contradiction this of terms—yet not uncommon in garden names—of "White Black Mullein," which must I suppose be the literal translation of *V. nigrum* var. *album*—the botanical term? The only popular name I know for this *Verbascum* is the "Dark Mullein," and the name "White Dark Mullein" is far from satisfactory. *V. Thapsus* might well spare one of its popular names to this species. Other fine *Verbascums* are worthy of note, but many other plants must have at least passing notice.

Great Sea-Thrifts have been crowded with heads of flower; Stonecrops, with thick and fleshy leaves, have covered themselves with yellow flowers of brilliant hue; the old Moly (*Allium*) has lit up a border with its golden blooms; the pretty pink *A. falcatum* has shown its pleasing flowers, which, alas! are of unpleasant odour; Sun Roses and Rock Roses have displayed their fleeting charms; tall and dwarf Linarias or Toad Flaxes have covered the

rockeries with dense carpets, pleasing tufts, or have uplifted their pretty spikes in the border; the white *Sidalcea candida* has been admired with its Mallow-like flowers in long erect branches; *Linum flavum* with shining yellow blossoms, and many other flowers have proclaimed with no uncertain sound how lavish flowers are in responding to the care of him who loves them truly, and finds delight of the sweetest kind in their company.

One could speak and write for long enough of the many more in flower, but I am aware that Rose shows and other claims will press sorely on the space of the Journal, and I have no desire to deprive rosarians of their due, but hope they have been and still are enjoying the fruits of their anxious care in reaping a rich harvest of beauty.—S. ARNOTT.

### THE WATER SUPPLY OF OUR GARDENS.

A PERIOD of prolonged drought like the present one brings to our minds with irresistible force the advantage, nay absolute necessity, of providing gardens of all descriptions with a plentiful supply of water. It seems to me that it is only at such exceptional times that we fully realise how much we are dependant upon water as a prime factor in the achievement of cultural success in any department of gardening. No matter how well all other details of culture are attended to, a scarcity or too stinted use of this indispensable element brings to the level of mediocrity the work of able cultivators, who with plenty of water at command, would be skilful gardeners. In many instances it is painful to see the looked-for reward of long hours of labour, snatched as it were from the grasp of the cultivator whenever a temporary absence of rain occurs at a period when various plants and crops have reached that critical stage of their growth at which copious supplies of water make all the difference between success or failure.

These thoughts and lessons have again been brought forcibly to my mind by visits to gardens of many descriptions, and by a quiet walk among allotments in various localities. The great contrasts presented in the appearance of these must leave upon the minds of many, beside myself, a vivid impression not soon to be forgotten. In some allotment gardens the sight was pitiful to behold, as no provision whatever had been made for a supply of water, and they were situated too far from the homes of the cultivators or other sources of supply to enable them to water even on a limited scale. The result was that hundreds of plants which had been set out after a few slight showers were either dead or dying, while other plots of ground which, during ordinary seasons would have been fully occupied, are yet practically barren wastes, the occupiers having recognised the uselessness of planting or sowing in soil almost as arid as the desert sands when no water is within reach. Among so much that was depressing one promising feature, however, stood out clear and bold, viz., the absence of weeds, and general tidiness which prevailed. Surely there never was such a splendid season for ridding our gardens of weeds, and it augurs well for the future to see cultivators on all sides taking advantage of it.

It was pleasant to turn from the parched and barren garden plots above referred to, to a group of others laid out within easy reach of the river Avon. Through being thus close to the water the soil was no doubt cool and moist in comparison to that in more elevated situations, but in addition to this advantage there were unmistakeable evidences that the river water had been freely used. Although no special provision had been made for conveying it to the crops, water carts, buckets, and cans were being pressed into service at the time of my visit, with an amount of energy not easy to excel. The work was without doubt very laborious, but the results achieved in keeping young crops advancing steadily, instead of gradually dwindling away or dying outright, seemed to give the owners ample satisfaction even now; but the advantage thus gained will be even more apparent later on when the crops which are receiving timely attention approach to an early maturity.

Numerous private gardens both large and small at the present time differ quite as much in appearance as those previously mentioned. Speaking broadly, this difference may be fully accounted for by the facilities which exist in each for the supply and distribution of water. The gardener who is well equipped in this respect has no dread of the approach of drought; on the contrary, he knows it to be a time when his productions show up with conspicuous advantage by the side of his less fortunate neighbours. How often have we wished in vain for a

spell of bright sunny weather, for the lack of which our English climate has been frequently abused. Now, however, that we are having sunshine enough to satisfy the most chilly person we find the water supply of our gardens has heretofore received too little attention, for it is an undoubted fact that were we to receive the amount of sunshine the majority of individuals crave for, our usual rainfall would be totally inadequate. It is also true that given a fertile soil and an unlimited supply of water, the county which receives that greatest amount of sunshine brings to maturity the heaviest crops. The rainfall of Britain would therefore require to be doubled in order to enable us to mature the fullest crops our soil and climate are capable of producing during seasons like the present one, lack of moisture being the one thing which now limits production. This view is fully supported by the experience and observation of the writer, and may be made equally apparent to anyone who will mark the distinction between plants and crops which are now receiving as much water as they require and those only receive comparatively a very limited amount, no matter whether we seek our illustration in the flower or kitchen garden, plant house or vinery. In every instance the season has been a grand one for the production of superior results where water has been copiously used, and I shall look forward to seeing both fruits and vegetables in high-class condition at many of the approaching shows.

One word about water in connection with the germination of seeds. On all sides I hear complaints about the patchiness of seed beds, and the disappointment resulting from the failure of seeds to germinate. I doubt not that many seedsmen will be inundated with complaints respecting the quality of the seeds supplied, but the real cause of failure must decidedly be attributed to the dryness of the soil in which the seeds were inserted. With us seeds of all descriptions have never come better, as we are happily situated in regard to a water supply, and were able to give every seed bed a thorough soaking with water just at the critical stage. Having at various times contended with the drawback of an insufficient supply, we are able to appreciate our present fortunate circumstances in this respect. I hope that the lessons taught by this sunny season may be the means of bringing about a vast improvement in the water supply of hundreds of British gardens, knowing well that the energy and skill of many gardeners are sadly hampered by having in use only primitive methods of distributing water, notwithstanding the fact that the hydraulic ram of present times is a powerful and economical invention for effectively performing that work.—H. D.

MAXILLARIA SANDERIANA VAR. XANTHOGLOSSA.

As will be seen by the illustration (fig. 89), this is a very fine variety of *Maxillaria Sanderiana*, and when exhibited by Messrs. F. Sander & Co., St. Albans, at the meeting of the Royal Horticultural Society on April 25th, an award of merit was adjudged for it. The flower is large and showy, the sepals and petals being white densely spotted with crimson, deepening to a dull reddish shade in the centre. The frontal portion of the lip is fimbriated, and a pale yellow shade. It may be interesting to remind readers that the type was first seen in flower at the Orchid Conference in 1885, and was then considered one of the most beautiful Orchids in cultivation. The variety depicted, however, is an improvement on the flowers of the species.

### TEMPERATURE FOR MILTONIA VEXILLARIA.

ALTHOUGH many growers succeed with this charming Orchid in the cool house there is no doubt that better results are frequently attained by giving it as high a temperature as most *Cattleyas* require; but perfect cleanliness and good drainage are essential. The first is secured by a constantly moist atmosphere, frequent examination for black thrips, and spongings if necessary; the second by filling at least two-thirds of the pot with crocks, and using only the very best peat, from which all the earthy particles have been shaken away, in the compost. This should consist of the above and live sphagnum moss, with a few nodules of charcoal added. The plants must be elevated  $1\frac{1}{2}$  inch above the pots, and careful watching is necessary in winter to prevent the decay of the base of the pseudo-bulbs from over-accumulation of moisture.

## VENTILATING ORCHIDS.

No doubt "J. E." (page 474) is right in supposing that the Orchid houses he refers to are insufficiently ventilated. The practice of leaving a house of Orchids of any kind closed until the temperature reaches a certain limit is decidedly wrong, especially at this season of the year, when a little air should always be admitted day and night.

With regard to the *Odontoglossum* house the day treatment is right, both as to shading and ventilating; for with the temperature outside at 80° or more it is little use having the ventilators wide open, as this only causes a dry atmosphere. Anyone experienced in the culture of cool Orchids has no need to look at the thermometer in summer. If the house feels pleasantly cool and moist on entering from the external air one need have no fear on that score. A good test, too, of *Odontoglossums* and kindred plants is to pass the hand lightly over the foliage. If this is firm, rustling to the touch and springs back readily to its place when the hand is removed, all is well; but if on the other hand it is soft and flabby, then the sooner the plants are given more air and less heat the better. At night abundance of air can be left on, unless the wind is very rough, for it is impossible to keep the plants too cool for the next two or three months. After the end of August the night air must be gradually reduced, but it will seldom be found necessary to quite close the bottom ventilators if these are either opposite to or just below the hot-water pipes.

The *Cattleyas* will not require so much air at night as the *Odontoglossums*. Where the lantern system of ventilation is in vogue and the air is admitted the whole length of the house, an inch on warm nights, and half an inch if there is much wind, will suffice. The grower must be guided by the weather by day as to giving air and shading. For *Cattleyas* the blinds should be kept up a little while after the air is increased in the morning, but not long enough for the leaves to get too hot. One day the sun may do no harm if allowed to shine on the leaves for a couple of hours, while another day half an hour's sun would scorch the leaves and disfigure the plants for years. This is especially the case after a few dull days, or after a thunderstorm, when the air is clear and the sun bright. Watch the plants when the leaves begin to feel warm to the touch, then lower the shading, but not before.

For a mixed house of Orchids it is difficult to give any definite instructions as to ventilating and shading, so much depends on the plants that are grown. For example, take two well known Orchids that are often seen growing in the same house—viz., *Dendrobium nobile* and *Cœlogyne cristata*. The former can hardly have too much sun if there is plenty of moisture in the atmosphere, while the latter cannot be better placed than in a shady corner.

It must be evident to "J. E." that no specified time can be given for airing or shading, but a well balanced atmosphere as to heat, air, and moisture should be always maintained. Then by arranging the plants in suitable positions according to the wants of the various species and the different stages of their growth many of the difficulties of a mixed house will be overcome.—H. RICHARDS.

## ORCHIDS AT SUNNINGDALE PARK.

For a collection which was formed only two years ago this is a very fine one. Many species and varieties are cultivated, and almost without exception the plants are in the best of health and vigour. A range of glass has been built expressly for Orchidaceous plants, and it is in a great measure due to Mr. Joicey, jun., who is a veritable enthusiast among Orchids, that such an excellent selection has been obtained in the limited time. During the time that this gentleman was travelling abroad he very kindly sent home upwards of a thousand plants of various kinds, many of which were at the time of my visit making such growth as an Orchid lover delights to see, the foliage being clean and substantial. One cannot be surprised at a gentleman taking an interest in them when he has such a hard-working and conscientious gardener to look after the plants as is found in Mr. Thorne.

Amongst the most noticeable in flower were *Oncidium Gardneri*, *Epidendrum radicans*, an exceptionally fine plant, *Oncidium pulvinatum*, which has a grand spike smothered with its starry yellow flowers. Some very beautiful varieties of *Cattleya Mossiae* were to be seen, and also some *Cypripediums*, amongst which a seedling of Mr. Thorne's own raising was decidedly pre-eminent. *Angulor Clowesi*

and *A. Ruckeri*, were very good, *Sobralia macrantha* in grand form, *Vanda Batemanni*, and a very dark form of *Cypripedium barbatum*. But the feature which reflects the greatest credit on the grower is a group of *Miltonia* (*Odontoglossum*) *vexillaria Cobbiana*. The plants in 4½ and 6-inch pots are arranged in a low lean-to house facing due east. Many of the plants have over forty blooms on them, and the colours range from an almost pure white to a rich deep rose. I measured a bloom on a plant in a 6-inch pot carrying eight spikes each with six flowers, and found it to be 5¼ inches in depth and 4¼ in width.

There were many other things at Sunningdale Park, to which I will refer in an early issue of the Journal.—W.

## THE ROCKERY IN MAY.

SURELY never have things been turned so topsy-turvy in the domain of horticulture as they have been this year, and in no part more so than in the herbaceous and alpine plants, which have

FIG. 89.—MAXILLARIA SANDERIANA VAR. XANTHOGLLOSSA.

been so largely grown of late years, a fact to which the Temple Show bore ample testimony. I do not think that the plants have as yet suffered much. It has, however, decoyed them in their time of blooming, and we are seeing things in flower now which we should look for in ordinary seasons a month hence, while those which we have looked for at this season are long since past. In looking over my small rockery during the latter days of May I found the following plants doing well, and as some of them are sometimes difficult to grow I may here state my method of treating them.

*Onosma tauricum*, I believe, is a difficult plant to flower in cold or damp situations; I know that in the climate of Cheshire it is almost impossible to keep it, much less to get it to bloom. I have placed it on an elevated position in the rockery and there it has stood unharmed during the severe winters we have had of late years. It is a very striking plant with its long pendant racemes of yellow blooms which are freely produced and last a long time in flower. I do not think that I have noticed in any descriptions of this plant the peculiarly strong almond perfume emitted by the blooms, and which my daughter brought to my notice. Inhabiting as it does the Caucasus, in high altitudes it is perfectly hardy, and I imagine like many plants of a similar character it suffers more from damp than cold, and perhaps from the varying character of our winters.

Nothing more surprises visitors who do happen now and then to visit my garden than to see *Gnaphalium leontopodium* flowering. They have been so accustomed when visiting Switzer-

land to have it associated with the inaccessible crags of Alpine ranges that they are quite surprised to see it flourishing. It is perhaps for these associations a somewhat overrated plant, though there is a great beauty about its soft flannelly foliage and flower stems. My clump is several years old, and the plants were raised from seed gathered here. There are many varieties of *Aubrietias*, the best of them being seedlings from *A. græca*. But none of them is comparable in beauty to *Aubrietia Leichtlini*, raised by the distinguished hybridist, Herr Max Leitchlin. It is quite as vigorous as the type, and is of a beautiful rosy pink colour, the buds as they open being nearly crimson.

*Gypsophila repens* is a pretty little white-flowered trailing plant, running freely over the rockery, and very useful for cutting for small vases. After many unsuccessful trials of *Campanula pulla*, which is in many places almost a weed, I have succeeded in establishing a good clump of it, which I obtained from my friend Mr. Carrington-Ley, on a piece of rockery facing east. Its deep purple flowers, borne on slender stems, make it a very pretty object in the lower part of the rockery; but care must be taken that larger plants do not interfere with it.

*Dianthus alpinus* is one of the most charming of alpine plants, with dwarf bright green foliage, which is, however, entirely covered when it is in flower, the flowers being of a bright rosy pink  $1\frac{1}{2}$  to 2 inches in diameter. *Dianthus neglectus* is a bright pink flower, produced on stems from 4 to 6 inches high; but some doubt appears to exist as to whether what is known as such in the trade is the real *neglectus*. *Dianthus deltoides* is one of those rock plants which the grower will have to watch very closely, not because it is delicate, but for the very opposite reason. It is so robust, and so increases by underground growth that it is apt to spring up in all places and smother other plants. *Dianthus cæsius* is the well-known Cheddar Pink; a native plant, very fragrant, and easily grown. *Dianthus fragrans* may be called a dwarf single form of the common white garden Pink—like it, the petals are deeply serrated, and the flower is very fragrant.

*Cypripedium spectabile* being in flower at the end of May is a remarkable proof of the earliness of the season, for I have seldom had it blooming before the end of June. I had also feared the drought would have considerably injured its vitality as it is essentially a moisture-loving plant, but I am glad to find that this is not the case, and that my clump, which I have had now for ten or twelve years, has flowered well. Its white flowers with the rosy labellum make it a conspicuous object on the rockery, and always attract the attention of visitors.

*Campanula turbinata* is a well known dwarf free-flowering species, comprising many varieties very easy of culture, in fact quite taking care of itself. The flowers are sessile and large considering the dwarf character of the plant. Many of the *Saxifragas* are noticeable for the beauty of their foliage, others for their huge panicles of showy flowers, but I know of none of them which for the delicacy of its pencilling equals *Saxifraga MacNabiana*.

The long period of drought seems to have suited *Sempervivum arachnoideum* admirably, wet weather to a great extent destroying the beautiful webs which cover its surface; indeed, it does not seem to mind how much it is baked. I recollect finding it in the clefts of some rocks on the Mauvais Pas near Chamounix, where it was fully exposed to the blaze of the sun, and did not seem to have a morsel of earth in which to root, so that this summer it has been quite at home.

*Omphalodes Luciliæ*, whose flowers are the most peculiar shade of blue, unlike that of any other plant I know, does not seem to be one very easy to manage—not that I lose it, but the plant does not seem to increase in size, and it is most difficult to propagate by division of the roots, at least I have found it so. I tried it once, and it was a most egregious failure. Another defect which I find in this beautiful flower is the smallness of the trusses, as I can never get more than three or four blooms out at the time.

*Heuchera sanguinea* has again flowered, but not at all in the way in which I am told by some of my brother gardeners it does with them. I was advised by somebody (I think it was Mr. Cocker of Aberdeen) at the Temple Show to break it up after it had flowered, and immediately replant the crowns. I was not to mind the flagging of the plant under the process, as it was its too great luxuriance under cultivation which prevented its flowering, as it does in the wild state. There may be something in the theory, and at any rate I mean to give it a trial.

Such is the record of my small rockery in the month of May of this year. Of course, it is not such an one as I should have in ordinary seasons, for many things have prematurely passed out of bloom; but it will be seen that even in this exceptional season there are some things to interest and please.—D., Deal.

#### ROSE SHOW FIXTURES IN 1893.

- June 24th (Saturday).—Reigate.
- „ 26th (Monday).—Canterbury and Hitchin.
- „ 27th (Tuesday).—Maidstone and Sutton.
- „ 28th (Wednesday).—Clifton,\* Earl's Court, King's Lynn, and Richmond (Surrey).
- „ 29th (Thursday).—Eltham and Windsor.
- July 1st (Saturday).—Crystal Palace (N.R.S.).
- „ 4th (Tuesday).—Bagshot, Diss, and Gloucester.
- „ 5th (Wednesday).—Croydon, Ealing, Farnham, Hereford, and Lee.\*
- „ 6th (Thursday).—Bath, Farningham, Manchester, and Norwich.
- „ 7th (Friday).—Ulverston.
- „ 11th (Tuesday).—Harleston and Wolverhampton.†
- „ 12th (Wednesday).—Earl's Court and Tunbridge Wells.
- „ 13th (Thursday).—Worksop (N.R.S.), and Woodbridge.
- „ 14th (Friday).—Helensburgh.
- „ 15th (Saturday).—New Brighton.
- „ 20th (Thursday).—Bedford and Trentham.
- „ 25th (Tuesday).—Tibshelf.
- „ 27th (Thursday).—Halifax and Southwell.
- „ 29th (Saturday).—Bedale.

\* Shows lasting two days.

† Show lasting three days.

During the present month a list of Rose Show fixtures will be issued each week, so that I shall be glad to have early notice of the dates of any shows not mentioned above, and also of any change of dates.—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts.*

#### TRAIN ARRANGEMENTS FOR THE NATIONAL ROSE SOCIETY'S PROVINCIAL SHOW AT WORKSOP, JULY 13th.

THE 10.40 P.M., out of King's Cross, Great Northern Railway, on July 12th, is to have a special van for Rose boxes, and will stop at Hitchin. The 5.15 A.M. will take up at Retford, and have a van from there for convenience of those coming from the North. This will enable exhibitors to get to Worksop at 8.31. The 7.15 A.M. is to have a special van.—J. MALLENDER.

#### THE OLDEST ROSE TREE.

IT interested me to see in last week's *Journal of Horticulture* (page 420) a note about the old Rose tree at Hildesheim, and I thought it might interest you to see the accompanying photograph, which I brought from Hildesheim in remembrance of my visit (in 1882) to the Cathedral there, and to the "oldest Rose tree" in the world. Unfortunately I did not see the tree in bloom, as it was too late in the year, but we were told it had been a perfect picture that year, so covered was it with blossoms.

The tradition, as I was told it in Hildesheim, was that the King while hunting in the forest, lost a precious relic, and vowed if he found it he would build a church on the spot. It was found caught by the chain on a Rose bush, and he built a chapel there, so that the Rose tree grew against the wall. The chapel being added later on, became the cathedral, and certainly is of much older date than the rest of the building. I think the King who founded it was not Charlemagne, but his son Louis the Holy, as he was called.

The stem of the Rose is of great size, and has had to be fenced in with a high iron railing to preserve it and the tree from the depredations of tourists. This is nothing in the way of information, but I thought it might interest you to see the photograph.—MABEL MAJOR, *Cromwell House, Croydon.*

[We are obliged by the photograph, which is, however, not suitable for reproduction, and for Miss Major's interesting communication.]

#### THE PRAIRIE ROSE.

RECENTLY garden literature has much to say of the beauty of the wild single form of this American Rose. It has been long cultivated in the nurseries of the conductors of "Meehan's Monthly," and they can bear testimony to the special beauty of this species. It comes into flower just as the ordinary garden Roses are going out, and before the autumn Roses appear, and the flowers, though each comparatively small, are borne in such immense clusters that the effect from the beauty standpoint is very grateful.

One singular point about the Rose is that when found growing wild north of the Potomac, as it often is—indeed, the specimens under cultivation as before cited are from Pennsylvania plants—they seem to be perfectly sterile, never attempting to make any seed, and for this reason no opportunity has been afforded to endeavour to improve the race by seed; but it must produce seed further south, as the Baltimore Belle and Prairie Queen were raised in Baltimore from these wild plants by the late Mr. Samuel Feast. In native localities further south it seems to produce seed freely; at least, the writer of this noticed it producing seed abundantly in the cave regions of Kentucky and round the Kahokia mounds in Illinois, near St. Louis.

## ROSE, DUCHESS OF BEDFORD.

I HAVE to express my obligations to Mr. Harcourt P. Landon for the information he gives me on page 480 of your issue of last week. I find that regarding the origin of Rose Duchess of Bedford there is a very considerable and conflicting difference of opinion existing between the great British rosarians. In his list of 2000 distinct varieties, Mr. Cranston of Hereford attributes the origination of this, one of the most beautiful and brilliant Roses in cultivation, to the Waltham rosarian. It is on the other hand assigned to Mr. R. B. Postans by Mr. Cant of Colchester, who being an intimate personal friend of Mr. Paul is not likely to deprive that venerable Rose cultivator of any honour that especially belongs to him. That Mr. Paul was at least the first introducer and extensive cultivator of the Duchess of Bedford I cannot doubt. This continental fame does not, most fortunately, rest upon the Duchess, or even upon the more celebrated Duke of Edinburgh, the latter of which was unquestionably raised by him in 1868.

Next to Mr. Paul among British raisers I would place without hesitation the late Mr. Bennett, to whom we are indebted for Her Majesty, Mrs. John Laing, and Lady Mary Fitzwilliam. The last mentioned Rose, however, is entirely eclipsed, whether as regards form, substance, exquisite colour, or superb fragrance, by her more highly endowed daughter "White Lady," a Waltham production. Like Mr. Turner's Polyantha Rose, whose success at Paris is extremely gratifying, it is a production of inestimable importance.—DAVID R. WILLIAMSON.

P.S.—Since writing the above note on the Duchess of Bedford I have received a letter from Mr. Paul, in which he says that the Rose in question was raised by Mr. Postans, but popularised by him. I am glad to have such an authoritative decision upon this subject. Mr. Paul, as I have indicated, does not require the Duchess to add to his reputation.—D. R. W.

## STRAY NOTES.

"My attention has been called" to a statement in London, and even in Dublin, evening papers to the effect that "the well-known grower of Roses in Suffolk, Mr. ——— (Christian and surname given in full) was deceased." As a matter of fact, the person in question, who has thus had a very rare opportunity of tasting posthumous fame, is alive and—well! would be "kicking" if due reason and a fit and proper object for that exercise could be shown him.

The drought increases in intensity. We are now contemplating hanging Professor Falb for an opposite reason, for he said we should have rain in June. The heat and the glare, and the "sharp dry," as it is locally called, of the east wind are trying for Hybrid Perpetuals and even for some of the Teas; and Rose showing must be a most vexatious and trying business in such weather. I am very pleased to see that Mrs. Paul (Bourbon) stands it well. My blooms are as firm and lasting as they were last year. Of its companion gold medal Rose, Salamander, the same cannot be said, I fear, in spite of its name. There is ample excuse for a Rose of that class appearing flabby in such a season; but it appears to me to be also a weak grower, and it is certainly strange that I have not seen any account of its having been exhibited, even by the raiser.

They are to be congratulated who have not been driven by the past cold and wet seasons to discard slow-opening and "hot season" varieties. It ought to be a good year for Marie Rady, Reynolds Hole, and Star of Waltham among Hybrid Perpetuals; and as for Teas, with Boule d'Or, Madame Margottin, and Madame Willermoz throwing themselves open as freely as Anna Ollivier, where, oh! Page Roberts, are those Marie Guillots which were our envy and despair in days that are past?

Violet Bouyer, as usual, won the race among Hybrid Perpetuals as being the first out; a dead heat for second place between Monsieur Noman and Captain Christy (the former rejoicing in the weather and coming very good, but, alas! too early), with Mrs. Baker in close attendance as third, and the others not far behind. Margaret Dickson at present shows no signs of giving any compensation for the disappointment of last year; but the two Irish Marchionesses, who are not lacking in embonpoint, should have a good time. The Marchioness of Dufferin has come quite good with me, and probably likes this sort of weather.

I am obliged to Mr. Mawley for his ample corroboration of my anticipation that the earlier grubs and caterpillars were to a great extent destroyed by pruning. Later pests which would not be thus affected are as numerous as ever. Aphides are more in evidence than usual, the little caterpillar which disdains leaves and appears first on the well developed bud only, is the cause of some quite private remarks, and that Beast (capital B) in the shape of a white maggot, which bores its way downwards from the top through the centre of the longest and strongest shoots which have not yet shown the bud, is really enough to make one tear one's hair, for there is no discerning the mischief till it is done, and are not these shoots our only hopes for the later local shows?

Of other pests mildew is unusually early, and bids fair to do a good deal of harm. As for orange fungus, of which Mr. Abbey discourses so fully (page 481), and which formed the subject of a symposium in the "Rosarians' Year Book" for 1887 (Mr. Worthington Smith's contribution being very clear and well illustrated), I have found it

practically unworthy of notice. Full of apprehension I most carefully carried away and burnt every sign of it in 1888; but finding no benefit in the autumn, and realising the next year that it really did me no practical harm, I have since left it alone, and do not find it increase.

It does, in the secondary stage, cause a great falling of the lower leaves in autumn, the Victor Verdier race being particularly susceptible. But though this is unsightly it does not seem to me that the vigour of the plants, or their capabilities for producing first-class blooms in the season, are thereby diminished.—W. R. RAILLEM.

## CANKER IN FRUIT TREES.

FOR more than one reason it was thought desirable to defer the publication of the following communications, mainly, though not wholly, commenting on Mr. Abbey's comprehensive articles which appeared on pages 47, 68, and 98 in January and February of the present year.

I READ Mr. Abbey's remarks on the various Apple growing soils of the country, and also his comparison of the Leeds soil with the Sittingbourne soil. I think in the main his deductions are correct, and that ammonia is needed to render the iron available for plant food, which was one of the things I suggested in my first letter on this subject. One error Mr. Abbey appears to have fallen into for want of more information as to subsoil, which I would have given had I anticipated his article, for he supposes our soil is different from the Kentish rag, which grows what he calls "the large bright matchless Kent Apples," whereas it is identical, for the parish of Leeds is situated on the ragstone formation, the technical geological name of which is the Hythe beds of the lower greensand.

The ragstone range of hills, which is about three or four miles wide, runs parallel with, and situated about a mile from, the North Downs, the soil in the valley between being composed of gault and some soft sandstone. On the southern side the Weald clay comes right up to the ragstone, consequently we are able to grow such Apples as your correspondent describes and other fruits remarkably well. Hops also do well. Before coming here I spent a considerable time examining the various soils in the county and looking to see which suited fruit best, and came to the conclusion that on the whole this soil was to be preferred, although most fruits do well on the brick earth near Sittingbourne, Strawberries near Swanley, and Apples in the Weald. The sandy soil about Swanley is of course not nearly so rich as ours, but if it is regarded merely as a substance to hold the tree up, and plentiful applications of manure are given, fruit will do tolerably well, for there does not appear to be anything injurious in it. I had to wait a couple of years before I could obtain ground, but latterly, since prices have been lower than what they were, it is much more easy to obtain ground.

A stranger not knowing anything of the whereabouts of the ragstone range would be able to trace where it began and left off simply by reason of the fact that fruit plantations and Hop gardens, which are such a remarkable feature of it, cease almost entirely directly one leaves it. Notwithstanding the high quality of the Apples grown on this range, the trees canker, though how far they do so varies considerably. On the lower slopes of the range the rock is nearer the surface, and the ground is richer, and is lighter in colour, evidently from containing more lime. As the ground rises the soil is redder, apparently from lime being less abundant, and iron more so, until at the top the subsoil is a red clay, locally known as "red pin," thickly interspersed with ragstone *débris*, the stones of a darker colour than the rock lower down, and where they are embedded in the red clay are also of a red colour. The upper soil is much darker than on the lower slopes. The presence of such a number of stones causes very good drainage, so that even when there has been much wet, after a day has elapsed the ground usually "plumps up," as it is termed locally. No doubt the stones also prevent such a hard pan forming as described by Mr. Abbey. The present variations in the ground have perhaps been partly caused by the action of rain washing fine particles of the soil lower down, so that the lower ground is richer, as is always the case, and this has also been aided by the different crops cultivated.

The higher the ground the more the Apple trees canker. I would ask those who contend that canker is not a question of soil how they account for this fact? On the higher ground hardly any Pears will do well, the fruit of most varieties cracking so much as to be worthless, and the trees are unhealthy. Cherries do well almost everywhere, but on the higher ground are more liable to gum. The soil of which the analysis was given, and that of my own ground, is situated midway between the top and the bottom of the slope. It might be supposed from the fact of Apple trees cankering it was a poor soil; but it is not so. It is a rich brown loam in a very good condition; owing to the abundance of ragstone *débris*, is neither too heavy nor too light, and is well supplied with the principal elements of plant food. Experience shows that these are in a sufficiently available form, for all kinds of vegetables can be grown of splendid condition and quality, and, as I said before, fruits of high quality are cultivated. When the ground was last sold it made £100 to £150 per acre, hardly any being then planted with fruit. But although Apples of first-rate quality are grown, yet some of the trees of almost every variety canker. With some varieties there is only a tree here and there, and other sorts canker so much that it is impossible to grow them except for a few years. The soil which was analysed by Dr. Voelcker had not then had much manure for some time. Mr. Abbey and others of your readers who are interested will now more fully understand the nature of our soil. I have gone into the matter fully in hope of throwing

more light on this vexed subject, though I do not think much practical information will be gained without experiments in the way of plant food on the lines previously suggested by Mr. Tonks.

There is one point, however, which might be of practical importance. Mr. Abbey has given the analysis of a soil near Sittingbourne. What is now wanted is the analysis of a good Apple soil in the Weald of Kent. We can grow Black Currants and most fruits better than they can be grown there, but they beat us for Apples as far as clearness of fruit and healthiness of trees. As the soil there is heavy no doubt it contains a great deal of potash, which probably has something to do with it; but a comparison of the analysis of the two soils—as ours in the main is a good soil for fruit—would show in what the difference consists. I would undertake to get a sample of the soil for analysis, and would jointly bear the expense of analysis with others if it was considered worth while analysing it.—WALTER KRUSE.

WITH all respect to Mr. Abbey and other correspondents, I am strongly induced to believe that in determining a fungus to be the cause of canker in trees, they are putting the cart before the horse. My view is that of Mr. Tonks and other earnest inquirers—viz., that canker is a product of starvation in respect of the particular varieties affected, or in other words, it is a disease caused by the absence in the soil of the elements, which are essential to the healthy maturation of the wood. How is it that of two varieties of Apples or of Pears (and these two fruits suffer more from canker than any other) growing close together, under absolutely the same conditions, yet one is healthy beyond all question; the other cankers badly, and hardly ever ripens annual growths? The reason is obvious. One sort finds all that it needs in the soil, the other does not. Were the canker disease an epidemic that was contagious why should not all trees suffer alike?

I am not referring to young trees but to old ones, trees growing together, side by side, for forty years. Ribston Pippin, Alfriston, Wellington, cankering badly; Waltham Abbey Seedling, Cockle's Pippin, and Beauty of Hants doing splendidly. I mention these few sorts only. All on Crab stock; soil a deep, and not very sweet clay. Again, of Pears Alexandre Lambré, Thompson's, Nouveau Poiteau, and Williams' Bon Chrétien do wonderfully well, planted twenty-two years on the Pear stock. Beurré Diel and Beurré d'Amanlis canker very badly, fruit split and spotted, comparatively worthless; others, fruit perfect, clean, and delicious. Why is the canker, if it be a contagious fungoid disease, restricted to the latter varieties, and the former are perfectly healthy? We want something more than ideas to clear up matters of this kind. Why do contagious diseases attack some people and leave others alone? Because of predisposing causes. So it is the case with trees. The predisposing causes to canker are deficiency of tree food, the lack of essentials to health; in other words, of the formation of perfectly sound ripened wood. There is hardly any worse form of canker than is seen in the annual dying off of the young growths due to imperfect maturation. No wonder that stem canker is also in evidence all over the tree. Supply the roots with the essential food requirements, and the wood will perfectly mature; then, too, the canker in the stems will disappear.

When trees are old and the roots have gone deep into the soil, feeding them seems to be out of the question. Only the severe root-pruning and the renovation of the surface soil by removing the old and replacing it with new, also adding suitable manures, can furnish a remedy, except where it is determined to take the head of the tree clean off and replace it by grafting with scions from a variety that thrives well on the soil. Here we see the very same soil, roots, and stem that before could furnish for the old head only disease, now producing a perfectly healthy and productive head. What in such case becomes of the contagious theory? If anything could tend to court disease it certainly would be in the doing of all I have indicated. What we want to know in relation to this matter, and to enable us to discuss it intelligibly, is what are the physical needs or constituents of any variety of fruit that cankers badly, as compared with similar needs of sorts that on the same soil are healthy. That seems to be the only way to get at this canker trouble satisfactorily. In how many cases has it happened that younger trees showing signs of canker have been lifted, replanted in same place, and yet have been healthy afterwards for years? Simply because the roots were previously in soil that was devoid of wood and fruit constituents, and the lifting and replanting, so that the roots were in surface and fertile soil, furnished the needful constituents, and the tree was satisfied. Later, when the roots were again down in barren soil, the canker reappeared.

In the stiff clay of West Middlesex for many years certain Apples did splendidly, carrying healthy heads and fine crops. Then came a very cold wet summer, when the sap was crude and the wood unripe. A very hard winter followed, and during a period of intense hoar frost, wood of King of the Pippins, Lord Suffield, Wellington, and several other varieties was cracked or contracted by the frost in all directions, even branches so large as a man's arm being terribly injured. The trees have never recovered from that blow, and apparently never will. Still there were many sorts, Cox's Orange Pippin, Mank's Codlin, Blenheim Pippin, Yellow Ingestrie, and others that suffered nothing. The fact showed that some sorts had found even in a wet summer and on cold clay all their needs, whilst others had found them deficient. Wellington Apple has never been worth its salt in the district since; and in myriads of cases heads have been taken off and other good varieties put on, especially Warner's King, which seem to have been quite uninjured.

Mr. Abbey has treated readers of the *Journal of Horticulture* to a

scientific essay, but it will all the same satisfy very few. I prefer to follow Mr. Tonks to Mr. Abbey. When it is asked, Why does the nurseryman keep his trees free from canker? the reply obviously is, Because he always has young trees, which have had no opportunity to send their roots deep into unfertile soil. As to destroying the fungus by external applications, does anyone else suppose that in such way canker will be eliminated? Very few indeed. The fungus is but an ordinary parasite that fastens upon tree crowns and decayed wood or bark. We must find means to prevent canker, and then we shall see nothing of that parasitical ogre the fungus.—A. D.

I HAVE read with much interest the articles which have from time to time appeared in the *Journal of Horticulture* on the subject of canker in fruit trees. I am only an amateur without scientific knowledge, but having had experience of canker in about 100 Apple and Pear trees planted by myself about fifteen years ago, I gave the subject some consideration to try and ascertain the cause and provide a remedy. At first I thought it was caused by an insect, and then by fungus, but I came to the conclusion that the insects and fungus were due to the disease, and not the disease to them.

Canker may differ on various soils and in different localities. I am only speaking of it as it appeared among my own trees. I find it usually begins at the base of a twig or on some part where the bark has been bruised; that it begins in a very small way at first, and the sore or canker keeps getting larger until the bough is half eaten through and the twig wholly or partially dies. Seasons make a difference, a moist spring and early summer inducing a rather vigorous growth, succeeded by a dry time appears to encourage canker.

After trying several experiments, such as insecticides and cleansing the wound, I came to the conclusion, rightly or wrongly, that it arose from an imperfect flow of sap, the obstacle arising from a new twig or a bruise; also that my soil contains some ingredient which leaves at the obstacle in its upward or downward flow a minute sediment, getting larger during the summer and deviating by degrees the course of the sap until the sore or canker is formed.

As a remedy I cut off all the worst cankered branches, cleaned the remainder, pared off the top soil round the stems of the trees to about as far as I thought the roots would reach to the depth of nearly a foot, and put some strong decayed farmyard manure on the top of the roots, covering it with the top soil to induce the trees to find their sustenance near the surface instead of striking downwards to the poverty stricken and cankerous under-soil. The result was a complete success, and for several years canker almost disappeared from my Apple and Pear trees. It comes again after a time, but if I cannot quite cure it as the trees get older I can at least check it, and with older trees I accompany the operations with judicious root-pruning.

I get canker in Gooseberry and Currant bushes and Laurels (Caucasian), but these I leave to their fate, as it is easier and cheaper to replace them than try to cure them. I am of opinion that canker arises from the soil, and the only way to cure canker is to "cure" the soil, and that it is not dependent on outside influences.—THOMAS PENDERED.

#### NIGHT-BLOOMING CEREUS.

My plant of *C. Macdonaldiae* on the 17th inst. opened its seventy-second and last bloom. There had been many others which never developed. It commenced to flower on May 9th with five blooms, on the 12th it had eight, on June 3rd six, and on the 4th five flowers, and there were few nights without two or three. I have measured an individual bloom 16 inches across.—EDMUND TONKS.

HAVING noticed the remarks regarding the Night-blooming Cereus in the *Journal* (page 478), I enclose a photograph, which was taken by the magnesium light between 9 and 10 P.M. Your correspondent asks if it is unusual to have so many flowers open at one time. It may be so, for one does not often meet with it in private gardens; but my employer told me that where he brought our plant from he saw thirty-three flowers open at one time, that being at Ryde.

I have had my plant about six years, and it flowered last year for the first time. This season we had two blooms, and as a novelty the gardens were open for anyone who liked to come and see them. The flowers did not both open on same night. I think it a pity this plant is not more grown; it requires but little room, and I am sure the flower well repays for the fragrance and its size. I tried to get a cross, but was not successful, but shall try again another season should it flower.—J. GILBERT, *Rectory, Merrow, Guildford*.

[We are obliged by the small photograph, which illustrates one blossom fully expanded.]

THE under-mentioned particulars may be helpful in convincing Mr. R. Hilton, Faversham (page 478), that nine open blooms on a plant at one time are not in any way "unprecedented," as he has been informed. To him, no doubt, the sight may be unusual, but to us around this locality such an event passes by almost unnoticed, for in the garden of J. Duncan, Esq., Fernlea, Woolton, a fine specimen of this remarkable plant is to be seen. Mr. Griffiths, the gardener, has kindly placed at my disposal his diary, from which I have made the following extracts, omitting dates where the number of open flowers for one evening do not exceed six in number. For June, 1888: 23rd

and 24th, thirteen flowers; or a total of thirty-nine for the season. June, 1889: 18th, seven; 19th, seventeen; 26th, ten; July 13th, thirteen; total, fifty-eight flowers. July 7th, 1890, twenty blooms and a total of sixty-four; July 6th, 1891, six flowers; 8th, thirty-eight; total, 74 flowers. June 25th, 1892, eight; total, 22 flowers. June 7th, 1893, eleven, leaving twenty-four buds to open. During the autumn of 1891 a large shoot was accidentally broken off, thus accounting for the difference between the seasons 1891-92. We have been successful in keeping the flowers in perfect condition over a week.—HARRY CORLETT, *Woolton*.

**EVENTS OF THE WEEK.**—Horticultural events of special interest are not particularly numerous during the ensuing week. To-day (Thursday) the annual dinner of the Gardeners' Royal Benevolent Institution will take place at the Hôtel Métropole, as announced in our last issue. A Show of Roses and fruit will be held at the Gardening and Forestry Exhibition, Earl's Court, on Wednesday, 28th inst.; and on the same day the annual display of the Richmond Horticultural Society will be held in the Old Deer Park, Richmond. The first annual Show of the Sittingbourne and District Rose Society will be held in the Town Hall, Sittingbourne, on June 29th.

— **THE WEATHER IN LONDON.**—The heat in the metropolis during the past week has been oppressive, and with the exception of a very slight local thunder shower no rain has fallen. Tuesday proved dull, and not quite so warm, as likewise did Wednesday morning, and at the time of going to press it is cloudy. Rain is much needed in the south.

— **THE WEATHER IN STIRLINGSHIRE.**—The highest shade temperature last week was 79°, the lowest 71°, with an average for the week of 77°. On Sunday at 7 A.M. it was 75°, and gradually rose until about 1 P.M., when it reached 90·5°, and at seven o'clock, evening, it recorded 74°. On Monday last the maximum was 83°.—G. MCDUGALL, *Ravenna Cottage, Stirling*.

— **THE PHILADELPHIA HORTICULTURAL HALL.**—The hall of the Pennsylvania Horticultural Society at Philadelphia was destroyed by fire a short time since. Fortunately, however, the most valuable portion of the Society's library was not damaged either by fire or water, and the valuable oil paintings of the founders of the Society were saved. The Directors have decided to erect a more spacious edifice on the old site.

— **FOREIGN POTATOES.**—Immense quantities of Potatoes were, according to the Board of Trade returns, imported into this country during May, the aggregate being 479,902 cwt. From the Channel Islands we received 228,788 cwt., as compared with 14,780 cwt. in the same period of last year. France sent 45,394 cwt., and Germany 106 cwt. only, against 846 cwt. in the corresponding month of 1892, and of 45,978 cwt. in May, 1891. From this it will be seen that there is a decided decline in the importations of Potatoes from Germany.

— **GARDENING AND FORESTRY EXHIBITION.**—The forestry section of the Exhibition is now fairly complete, and nearly all the exhibits promised by official bodies and private individuals are now *en évidence*. Among them will be found a most interesting consignment from Balmoral, lent by the Queen, as well as a vast number of examples of what may be termed the curiosities of forestry, illustrating abnormal growths and eccentricities of tree life. Other exhibits set forth the varying effects of salt and fresh water on timber, and ravages of insects.

— **SPRING SOWN CABBAGES.**—There can be no doubt as to the advisability of raising a few Cabbages in spring to follow those from seed sown in the autumn, as these latter are rarely good in quality after this date. We are now, June 15th, cutting useful heads of Sutton's Earliest from seeds sown in February, this allowing the autumn planted beds to be cleared and the ground cropped with ridge Cucumbers, Spinach, and other things. This variety is exceptionally quick in turning in, and when cooked is very tender and good in quality.—H. RICHARDS, *Rock Court, Salisbury*.

— **IMPORTATION OF APPLES.**—According to the Board of Trade returns for May the importation of Apples during that month amounted to 98,442 bushels, as compared with 91,608 bushels in May, 1892.

— **MR. D. MORRIS.**—We are pleased to see that Mr. Daniel Morris, the assistant-director of the Royal Gardens, Kew, has received the honour of appointment as Companion of the most distinguished Order of St. Michael and St. George.

— **OXFORD CARNATION AND PICOTEE UNION.**—We are informed that the annual Exhibition of this organisation will be held in Mr. Dodwell's garden on Tuesday, July 18th, the season necessitating holding the Show earlier than was originally intended.

— **BRITISH BUTTERFLIES.**—In the "Entomologists' Monthly Magazine" Mr. R. McLachlan, F.R.S., in an article on the extinction of several species of British butterflies within recent years and the apparent decadence of others, suggests the enforcement of a close time to last continuously during the whole of a series of five or ten years.

— **HORTICULTURISTS' CRICKET MATCH.**—Mr. R. Dean, Ealing, the Hon. Secretary, desires us to announce that on the occasion of the annual outing of the members of the National Chrysanthemum Society at Wycombe Abbey, on Monday July 17th, a match of cricket will be played with the members of the Aylesbury Horticultural Society, and he will be pleased to receive as soon as possible the names of members of the N.C.S. who are willing to play.

— **THE FERTILISERS AND FEEDING STUFFS BILL.**—In this Bill introduced by Mr. Herbert Gardner, it is proposed that every person who sells for use as a fertiliser of the soil any article manufactured in the United Kingdom, or manufactured abroad, shall give to the purchaser a warranty stating the ingredients used, and that where food for cattle is sold under a name or description implying that it is composed of any particular substance or substances, there shall be implied a warranty by the seller that it is composed of the substance or substances stated. The penalty for breach of the provisions of the Act is a fine not exceeding £20 for a first offence, and not exceeding £50 for a subsequent offence.

— **FORCING VEGETABLES.**—At the June meeting of the Dundee Horticultural Association Mr. M. Temple delivered an excellent lecture on "Forcing Vegetables." Mr. Temple referred to the means for cultivating forced vegetables, and remarked that early forcing in Scotland, so far as fruits and vegetables were concerned, was merely nominal compared with the practice in England in the majority of well appointed places. To successfully force Asparagus, strong, well ripened, and healthy roots and crowns were essential, each plant grown separately and freely exposed to the sun and air, so that the crown might be thoroughly matured. All kinds of vegetables suitable for forcing were dealt with, and a vote of thanks was accorded Mr. Temple.

— **SEAWEED AS MANURE.**—In an American contemporary it is stated that when this is used as a manure nothing is gained by allowing it to ferment. The best practice is to use it in its fresh state, either for ploughing in or for top-dressing grass lands, but as it contains 70 to 80 per cent. of water it will not pay to cart it a long way from the shore. Since it contains a comparatively large percentage of nitrogen and potash, it is not a well-balanced fertiliser, and needs to be supplemented by some material rich in phosphoric acid. It is preferred to stable manure for growing Potatoes, since they are less liable to the disease known as the scab than those grown on farmyard manure. Sea-wrack shares with commercial fertilisers the conspicuous advantage of being free from seeds and weeds, spores of fungi and eggs of insects.

— **MARGARET CARNATIONS.**—A number of these most useful Carnations are just opening hundreds of buds in the garden. If proof were needed to add to their popularity, I might mention that dozens of good named varieties growing in the same border have succumbed during the past winter, whilst the Margaret Carnations have stood untouched. Another proof was the experience of a neighbour of mine—Mr. T. Eaton, gardener to John Parrington, Esq., Roby Mount. In the autumn he found hundreds of buds on his plants outside, which seemed firm and likely to open. The plants were carefully lifted, put in 6-inch pots, and placed in the Peach house. Here they were flowered continuously throughout the winter and spring, and looked quite healthy. The value of plenty of Carnations with their sweet-scented flowers throughout the dull months may be readily imagined. The plants which are now coming into bloom are from seed sown in February, 1892, and they flowered all last summer.—R. P. R.

— THE ROYAL GARDENERS' ORPHAN FUND. — The Committee of this Fund held a meeting recently, when the Hon. Secretary announced the following special receipts:—From Mr. F. M. Mould, Birmingham, life subscription of 5 guineas, in place of an annual subscription; Mr. John Wills, Onslow Crescent, annual birthday gift, £10 10s.; Messrs. W. Thomson & Sons, Clovenfords, Galashiels, donation, £1 10s.; Mr. H. J. Jones, Ryecroft Nursery, Lewisham, donation, £1; young men at the Gardens, Ruxley Lodge, Surrey, per Mr. J. Miller, 10s.; and Mr. J. Perry, Crystal Palace Park, donation, £1.

— EXHIBITING RASPBERRIES.—A point which has often struck me when visiting exhibitions is the manner in which Raspberries are staged. Some are found with the stalks adhering to the fruit, others pulled out. I cannot help thinking that the former is much the best way to exhibit them. It is very seldom that we see a dish of Strawberries shown without the stalks, nor would they look so well, and why should the case be altered with regard to Raspberries? It is just to raise a little discussion that I have penned these few lines, and I am certain there will be many more besides myself who will be glad to hear the opinion of some of your readers on this subject.—R. P. R.

— WAKEFIELD PAXTON SOCIETY.—There was a large gathering of the members of this Society at the usual meeting last week. Mr. J. W. Macpherson, B.A., of Wakefield Grammar School, delivered a most interesting and instructive discourse on "Plant Adaptation for Fertilisation," illustrated with many fine lantern views, shown by Mr. Gregory. It is evident that Mr. Macpherson is an able and ardent botanist. In a chatty and humorous style he clearly explained how the seed vessels of various flowers are fertilised through the agency of insects in search of food, or by the wind, or currents of water in the case of aquatic plants. The mysteries of cross-fertilisation and self-fertilisation and the principles of development and degradation of various organs were lucidly set forth.

— CAN PLANTS SEE?—I do not suppose that "Scepticus," in inditing the note on page 478 recording what doubtless seemed to him to be a curious natural phenomenon, really imagines that plants are endowed with sight. What very probably happened in the case of this one particular Bean plant was that in staking the row it was irritated or its nerves influenced by a specially close contact with the stake, and that such irritation caused the points of the plant to circle round in search of the object which thus produced the irritation. It would be just as reasonable to assume that root spongioles in their search in the soil after food were capable of seeing as that the points of climbing plants should be so endowed. Nature has in each case provided facilities for searching but not for seeing. That is, at least, my theory.—A. D.

— THE ONION MAGGOT.—Looking over some 20 acres of admirably kept and cropped allotments (their first year as such) the other day, I could but remark upon the ravages created by the Onion maggot in every direction. There were considerably over 100 heads of Onions in diverse plots, and not one but was more or less affected. The best plot I saw was one sown thickly, and when I remonstrated with the grower for such apparent neglect in thinning, he said that he meant to let the plants stand just as they were, and if the bulbs were no larger than pickling onions he would be better off than most of his neighbours. The land had previously been under market cultivation, especially with Lettuces and similar crops, also heavily manured, and the allotment holders attribute this outbreak of the maggot largely to that. Of course such estimate is purely problematical. When asked for a remedy I had to admit that, so far as spring-sown Onions were concerned, it was difficult to specify one. When the best private gardeners were practically helpless in face of the maggot, what remedy could be recommended? It is obvious that once the fly has deposited its eggs, there is little chance of killing the pest. The best course seems to be to fork over the top few inches of the soil, on which Onions have been grown, several times during the winter, so as to expose the fly chrysalids to the birds; to top-dress early in February, not only old Onion beds but soil to be sown that year, with a dressing of gas lime, allowing it to lie six weeks, then forking it in; also not to sow more seed until from the middle to the end of April, so that when growth follows it may be quick; to frequently sprinkle the young plants with a solution of quassia chips and softsoap, and then dust with soot to render them obnoxious to the fly; and to have the soil as firm as possible. Probably one of the best remedies may be found in sowing Onion seed in the autumn, and then dibbling out plants into fresh soil at the end of March.—A. D.

— MESSRS. J. CHEAL & SONS' EMPLOYÉS.—The annual outing of the employés of the firm of Messrs. J. Cheal & Sons took place on Monday, the 19th inst.; Portsmouth and the Isle of Wight being visited. The Dockyard being first inspected, the company, numbering ninety-six, then adjourned to the Speedwell Hotel for luncheon, after which the party visited Osborne, Ryde, Sea View, and other places, returning to Crawley by the last train, all having spent a most enjoyable day.

— FLORAL FETE AT REGENT'S PARK.—A Floral Fête for children was held in the Royal Botanic Society's Gardens, Regent's Park, yesterday (Wednesday) afternoon. The idea of these fêtes, which are now held annually at the Gardens, is to encourage the use of floral decoration, such as may sometimes be seen at public ceremonies on the Continent. Awards were given for children's flower-dressed mail carts, sedan chairs, and ponies. A few special prizes were also offered for groups of plants, cut flowers, window boxes, and miscellaneous exhibits, to which a further reference will be made in our next issue.

— A RECORD FOR EARLY PEACHES.—We commenced gathering ripe Peaches in the open on June 18th, or fully a month earlier than last year, and I am disposed to believe this is the earliest date yet recorded. The variety is the Early Alexander, the trees being trained against a wall with a south-east aspect. At times this wall has been so hot soon after mid-day as to be almost capable of roasting the fruit, a south-east being the hottest of all aspects. The tree, when in flower, and for a few weeks after, was protected with doubled fish netting, and is carrying a full crop of fairly large, well-coloured fruit, those gathered being of better flavour than anticipated.—W. IGGULDEN, *Somerset*.

— SHEFFIELD CHRYSANTHEMUM SOCIETY.—The usual monthly meeting was held at Webster's Museum, Orchard Street, on June 14th, when some very fine British and Exotic Ferns were exhibited in competition by amateurs, and Pelargoniums by professionals. A very distinct and select collection of Gloxinia blooms, including some good spotted varieties, were staged by an amateur who was awarded a special prize. Mr. John Haigh presided over the meeting, and introduced Mr. Thos. Gartery of Rotherham, who gave an excellent practical essay on "Growing Roses in Pots." He dealt with his subject from almost every point of view. For pot culture he preferred Roses on their own roots. The advantages of growing Roses in pots were demonstrated, after which the chief points in culture were touched upon, including choice of varieties, habit of growth, contrast of colour, blooming qualities, form and outline of flowers, their keeping qualities and sweetness. He then gave a select list of Hybrid Perpetual, Tea, and Noisette varieties. Methods of propagation were clearly detailed, and the best compost for Roses given, followed by interesting remarks on potting, pruning, and training, and the prevention and destruction of insects and mildew.

— TRANSPIRATION OF TROPICAL PLANTS.—During a recent stay at Buitenzorg, in Java, Herr Haberlandt made some experiments in the Botanical Gardens on the transpiration of tropical plants. In general this was found considerably less than that of plants in Central Europe. Thus of seventeen tropical species, some with coarse, leather-like, others with tender leaves, nine species transpired per day and per square decimeter surface less than 1 gramme; in six the amount was between 1 and 2 gr.; and in two only it reached 2.6 and 3.25 gr. Now, with European vegetables and woody plants it varies commonly between 2 and 5 gr., and sometimes reaches 6 or 7 gr. or more. According to *Nature* this result the author considers a strong argument against the view that the transpiration current is of first importance in nutrition of land plants. These tropical plants, with their small transpiration, show extremely luxuriant vegetation, and are able through osmotic forces, doubtless, to convey nutritive salts to their highest parts. It is curious that, despite the great humidity of the air and the large amount of water in the ground, these plants often possess guards against too great transpiration, such as thick, cuticularised epidermis, deeply sunk stomata, and especially tissues adapted for storage of water. And the reason cannot lie, as sometimes at the coast, in the presence of salt in the ground. Herr Haberlandt finds an explanation in the fact that while the total transpiration is comparatively small, the hot sunny forenoons may occasion large evaporation. The transpiration in a forenoon hour was, in general, four to twelve times that in an afternoon hour; sometimes as much as twenty or thirty times. The forenoon hours are by far the most favourable to assimilation, and it is most important to the plant that its turgescence be not then too much depressed, an end accomplished through those water reservoirs.

— **WEATHER AT SWANMORE.**—With the exception of 0.02 inch of rain that fell on the 15th we have had thirty rainless days. The last previous rainfall was 0.15 May 20th. The total rainfall for the year up to date is now 6.87. Many shrubs that have been established for ten years are exhibiting a serious appearance for want of moisture. The heat during the last six days has been intense. A thermometer hanging on a north wall directly in a draught registered on the 19th 88°. Another with a northern aspect and hanging in the shade in the kitchen garden, reached 95°.—E. MOLYNEUX.

— **DOUBLE FLOWERS.**—A correspondent inquires how double flowers are produced. Many double flowers of gardens were first found wild. The florist, however, can produce double flowers. He watches this tendency in nature. If a flower usually has five petals, and he discovers that some of the stamens have somewhat of a petal-like character, the pollen is taken from these flowers and others in a normal condition fertilised with this pollen. This tendency once started is then given to the progeny. Almost any species of plant will, says *Meehans' Monthly*, in this way be capable of producing double flowers. It is surprising that with this knowledge, more attempts at this line of improvement in ordinary garden flowers are not made.

— **A NEW LUNG FOR LONDON.**—The Metropolitan Public Gardens Association added another open space to Hackney in the north-east of London on Thursday last. This new lung is situated in St. Thomas's Square, Mare Street, the site being given by the Governors of St. Thomas's Hospital. It has been tastefully laid out by the Association, while its future maintenance will be looked after by the Hackney Boards of Works. It was opened by Countess Brownlow, who on arriving was presented with a bouquet by Miss Holmes, the daughter of the Association's Secretary. The Earl of Meath presided over the gathering, and said that during the last ten years the Association had been enabled to throw open to the public no fewer than seventy-two grounds at an expenditure of something like £30,000. In addition to that they had prevailed upon the London School Board to open 178 of their playgrounds on Saturdays—practically the only day in the week which the children had to themselves. In the streets the Association had planted 2240 trees.

— **HORTICULTURE IN RUSSIAN SCHOOLS.**—There is now a general tendency in Russia to introduce some teaching in agriculture and horticulture into the primary schools. Both private persons and the provincial authorities freely give grants of land to the schools and to the teachers' seminaries for their fields and orchards, and in many schools the plots of arable land and gardens attended to by the pupils become small centres of agricultural and horticultural education. In *Caucasia*, says *Nature*, the same tendency is even more pronounced, and no better idea can be given of the extent of this new movement than by giving the following facts relative to the primary schools of Kuban, a province of Northern *Caucasia*. This year ten schoolmasters have been invited to attend the lectures upon sericulture and bee-keeping at the schools of the Cossack villages, Armavir and Labinskaya. The inspector of the schools has acquired, with the modest grant of £35, thirty appliances for raising silkworms, and five arrangements for each school for pumping out honey from the bee hives, and preparing the artificial wax honeycombs, in addition to which ten schools have been supplied with apparatus for silkworm culture, while others have been supplied with seeds of plants of special use to bees. All schools which have gardens of silkworm trees have been supplied with seeds of the tree, and 20,000 young trees have been distributed among them. Fourteen schools are expected this year to carry on the silkworm culture, and ten other schools are already carrying on experiments relative to the same.

## ABOUT HULL.—II.

### HESSEWOOD.

HESSEWOOD is so near the pleasant village of Hessle on the Humber side that ten minutes fair walking would probably suffice to take anyone to it from the station, unless, indeed, his powers as a pedestrian were extremely limited. The entrance lodge stands at the junction of four roads, one finger post pointing to Hessle, a second to Cave, a third to Swanland, and a fourth to a place of which the name was nearly obliterated, but apparently the river. I declined an unnecessary inquiry, and entered the gates of Hessewood. The estate is in the occupation of F. R. Pease, Esq., and the gardens are in charge of an old acquaintance, Mr. George Picker, formerly gardener to Mr. C. E. Shea at Foots Cray. He is a cultivator of much intelligence, and is doing good work in his new sphere.

The grounds have considerable attractions, and exhibit their fullest beauty in the ample leafage of summer. They are well furnished

with noble timber, amongst which some fine Evergreen Oaks are very conspicuous. Vistas of the river have been opened here and there amongst them, and the Humber at Hessle is not a mere line for the eye like the Thames at Twickenham, which is a streak of light so to say, with no pretence of filling the vision. The northern river must be nearly three miles across here, although its mouth is twenty-five miles away, and from angles which carry the eye up the stream towards its junction with the Ouse quite a broad sweep of water is viewed. This is a great advantage to the place, and the effect is not much less where the line of vision extends directly across the river to the swelling wolds of Lincolnshire beyond, for the shadows and glows upon them give pleasing effects. In the midst of vernal beauty it is an evil impulse which calls up thoughts of autumn, and conjures up ghostly visions of troops of fog fiends creeping up the valley, but they tell me that the terror of the Thames side has not serious dimensions in the East Riding. Happy Hessle!

What Mr. Picker does in the flower gardening way must be left to some future historian to say, for his plants were still under cover at the time of my call, and his plans locked within his breast. He has established a somewhat extensive rockery, and is adding other features of interest. The evidence of eyes and ears would suggest the reflection that Hessewood as it is to be will be a polished and improved edition of Hessewood as it is. In a hundred ways, little and big, the present chief is endeavouring to improve his charge and do credit to himself. His ideas are good, his taste evidently sound, his execution workmanlike. It is pleasant to see how, among the many bright and beautiful plants in the garden, Roses flourish as though thoroughly at home. Their growth is stout, vigorous and healthy. The more modest Pansies and Violas are also a sight to see. It is a glad recognition that heat and drought cannot quench their instincts for lavish blossoming, though like all things sentient, they would doubtless be grateful for genial showers. In its rich abundance of these delightful flowers, and in ample masses of autumn-sown annuals, what is known as Mrs. Pease's garden is a charming picture, bright, fragrant and informal.

From among a series of more than usually disjointed notes, some of which will have to go by the board, I will mention some very fine specimens of the old golden *Gymnogramma*. They are of considerable dimensions and in good health. There is also a grand plant of *Davallia Mooreana*. Hessewood does not indulge itself in giants in a general way, but these Ferns are beyond the average size. There are some fine specimens, too, in the way of *Hydrangeas*, huge plants in No. 1 pots, and 4 to 5 feet through, which are likely enough to find their way into the flower garden ere long. Another plant worth mentioning from its unusual dimensions is *Lapageria alba*, which is in admirable condition. A feature of the house containing the broad-backed *Gymnogrammas* referred to are some splendid baskets of *Adiantum cuneatum*. If not the most beautiful of basket Ferns the old Maidenhair is well worthy of being grown for the purpose. The Hessewood plants are of large size, well furnished, and in perfect health. Dwarf *Cannas* have nothing to boast of on the score of size, but they have in other respects. There are some seedlings 15 to 18 inches high that are now blooming well, and proving very valuable. The seed was sown in September last. Amongst several attractive varieties was a fine scarlet. It is worth while reflecting how useful these plants are for flowering under glass, and how readily they may be raised. *Carex marginata grandis* is held in high esteem, and the stock of it is large. The greenhouse, gay with Zonal Pelargoniums, Heliotrope, Musk, Chorozeas, Petunias, various Grasses, *Saxifraga pyramidalis*, Lilliums, Fuchsias, *Gladiolus The Bride*, Begonias, *Nicotiana affinis*, *Streptocarpus*, and a fine variety of Mignonette called Sutton's Giant, hardly, perhaps, calls for any special comment, save to observe that it is full of healthy and profusely flowered plants admirably disposed.

Circumspection is required in writing about one important item in the fruit department—the Vines. A doubt may be frankly expressed whether they would satisfy many critics. Assuredly they do not satisfy Mr. Picker himself, and it is safe to say that if he had had the training of them they would not display their present appearance. In addition to remedying the effects of what may be mildly described as a certain eccentricity in the matter of training, he is waging a determined battle with that sad pest mealy bug. He is such a determined man, and so deeply interested in his work, that he will eventually succeed in both. He has done a great deal in eleven months, and ere another year has passed he will have done much more. The bush fruit out of doors is being skilfully managed. Time is found to top and thin Currants and to insure finer fruit by dressings of potash and bone manure. Currants are also extensively grown on walls. Mr. Picker is evidently devoting great care to the whole of the fruit, and in due course the collection will be one to be proud of, as indeed will be the whole of the beautiful place under his care.

### SWANLAND MANOR.

"Swanland Manor, a mile and a half from Ferriby Station, about two miles from Tranby Croft," was my instruction in this connection. I disdained the station, and went, as I had come from Hull, by road. It is a delightful walk from Hessewood, leaving Tranby Croft on the right, and he would be as difficult to please as Mark Tapley himself who did not enjoy the route, even though conscious of missing the beautiful avenue at Ferriby House (Mr. John Ostler's), which could have been seen from the road in walking up from the station. As we cannot get through the world without sacrifices this had to be borne philosophically. The proprietor of Swanland Manor is James Reckitt, Esq., one of Hull's prominent men, a supporter of what superior persons call cheap culture for the

people, and, if report speaks truly, one who knows both a good book and a good picture. Such a man can hardly fail to be capable of appreciating a good garden too, for the one is quite as much a work of art as the other, and consequently appeals to the same instincts. A little more "cheap culture" of the garden kind would do good to many, including the critics. Mr. and Mrs. Reckitt take great interest in their estate, and have reason to be proud of it. Although denied the picturesque effects of a mere undulating country the ground has been so well laid out that the general effect is excellent; moreover, the timber is good, and that is a great deal in itself. The place is particularly rich in Thorns and Beeches, and on the tennis ground is a grand specimen of *Cratægus oxyacantha*, 30 feet high and about the same through. It is a really noble tree, probably one of the best of its kind in the country.

Mr. George Wilson, who has charge of the Swanland Gardens, has made a reputation as an all-round cultivator, and particularly as an exhibitor of *Chrysanthemum* groups. Victories at Hull have followed each other with a regularity which must have become very tedious to the other competitors, and a ubiquitous judge has pronounced Mr. Wilson's groups to be amongst the best, if not quite the best, he had seen. This being the case, it seemed appropriate enough that the head gardener should be found in his shed hard at work, in shirt sleeves and apron, potting *Chrysanthemums*. I fancied I detected a gleam in his eye that displayed enthusiasm or first prize next autumn; but this may have been fancy, decidedly there is no imagination about the plants. About 400 are grown, and they are making splendid progress. But plenty of other things are well managed; particularly should *Crotons* be mentioned. Table decoration is a considerable part of the gardener's work at Swanland, and these plants are therefore in great request. The collection is a large and very varied one, comprising *Weismanni*, *Queen Victoria*, *Warreni*, *Mrs. Dorman*, *variegatus*, *Johannis*, *Emperor Alexander III.*, *Princess of Wales*, *undulatus*, *Morti*, *nobilis*, and others. Where all are so clean, healthy, and richly marked it is difficult to make special mention; but *Queen Victoria*, *Mrs. Dorman*, and *variegatus* are magnificently coloured. *Caladiums*, *Dracænas*, and *Dieffenbachias*, all largely used for house work, are also extensively cultivated; indeed, it may be said that foliage plants are a special feature of the houses at Swanland. Mr. Wilson is an adept in their management—that can be seen at a glance, and they do him very great credit.

Palms are, as would be expected, in considerable request, and *Kentia Belmoreana*, *Phoenix tenuis*, and *Areca lutescens* are prominent amongst them. A less familiar plant, but one of great beauty as grown at Swanland, is the old *Amaranthus tricolor*. The beautiful rosy red colouring, broken with yellow and green, produces a distinct and glowing effect. *Eulalia japonica variegata* is not met with in every garden, and in few so good as under Mr. Wilson's care. Later in the season the plumes rise to a height of 5 feet, and play a by no means unimportant part in the prize groups. *Cyperus distans*, with its long slender green leafage, is in good force, and so are the two handsome "foliage" *Abutilons*, *teselatum variegatum* and *marmoratum*. To say that these are grown is to say that they are grown well. Somewhat of an oddity, but a very brilliant one, is a huge plant of *Cereus Jenkinsoni*. By oddity, I mean something out of the usual run of greenhouse plants. It has had 200 of its glowing blooms open at once, and those who are familiar with its colour can give themselves an idea of the effect it produces. The hue, or rather hues—for there seem to be all manner of strange shades and glows about the flower—are indescribable. The plant is in a 10-inch pot, and has not been repotted for many years. Of *Richardias* there are some stalwart specimens, capable of yielding abundance of spathes, which are greatly in request. Ivy-leaved *Pelargoniums* and *Gladiolus The Bride* are two other "leading lines," to quote the language of the commercial. Large numbers of *Gloxinias* are grown, and presumably these beautiful plants are special favourites. There is a splendid batch of Sutton's strain now in bloom, and 150 more coming in to succeed them. *Eucharises* are another prominent feature. Roses and Ferns naturally have particular attention, and the collection of Orchids is growing. Of the latter a fine piece of *Dendrobium suavisimum* full of bloom, and a grand plant of *D. nobile*, which had 700 flowers on it last year, are worth mentioning.

But little reference can be made to the fruit. Let it suffice to say that the Vines, rejuvenated by Mr. Wilson, are bearing excellent crops, and that the Peaches and Nectarines are equally good. Alexander, which at Hesselwood, two or three miles away, gives great trouble through refusing to stone, is in every way satisfactory at Swanland, and greatly valued; so is that grand late Peach, Gladstone. More might very well be said about these if thoughts of space did not prevail; but they form no exception to the general rule of excellence.—W. P. W.

#### IN MEMORIAM: SAMUEL BARLOW.

It is truly a very marked sorrow in my life to write this brief memorial of a dear old friend. I can only say what many others would, as I lay it for "a spray of Lavender" in the pages of the old *Journal*, or as a white wreath of loving words, to the memory of one whom all who knew him so well will never forget.

By no men was dear SAMUEL BARLOW more beloved than by his fellow florists. Just as flowers were the earliest choice of his childhood, and floriculture the favourite recreation in his busy after life, so the friends who gathered round him in share or sympathy in this were among his dearest, and seemed to see him in the very sunshine of his life. There is an attachment in this relationship through flowers for which there probably can be no quite kindred tie in the

cares, competitions, and responsibilities of business life. Still, however, in those there are very many who deeply grieve at the loss of one so true and just in all his dealings, and who gave so freely of his time and thought, not to his own interests and leisure, but to the public good. I know there were circles of other specialist friends around him, in the world of Science and Art; and not seldom have segments, so to say, of these circles met at Stakehill—the artist and the florist, for example—each to see types and triumphs in his own pursuit, each wondering at what was plain and well known to the other, each receiving some expansion of knowledge, and perhaps wishing there could be some transfusion of powers.

To those of us who as middle-aged or older men have known Stakehill, with an intimacy like my own of five-and-twenty years, it is not probable that we shall ever know the like again. There is not the lifetime left for it! The Primroses of life's spring, and the Buttercups of its June, cannot bloom in its mellow August and chill October. It is thirty-five years since I first met Samuel Barlow, and it was over a mutual grief in Tulips that acquaintance ripened till we were as brothers born. He had grown for twelve years the only constant feathered Kate Connor (Rose) there ever was, and for another ten years it was under my care. Then, in a travelling accident, and along with many other of my Tulips, "Kate" was killed. Thinking Mr. Barlow would have more of her I wrote, and found that neither he nor I had ever had an offset from this supreme feathered strain of Kate.

Just before the Stakehill firm became "S. Barlow & Co." it had been an anxious question with Mr. Barlow whether or no he should start business in America. But in all the anxious thoughts he had remembered his Tulips, and provided for their welfare under the care of his brother-in-law, Mr. Wm. Bentley, then of Royton, until he had a good home for them across the Atlantic. Most happily in every respect, however, he resolved to stay at the old English home, otherwise how many of us would have lost the many happy years of fellowship we have enjoyed with him! and the help of his love, enthusiasm, impulse, tact and discernment that he gave to the culture and improvement of the old florist flowers.

It is only fair to say, as quite independent of all regard for him as a loved friend, that we have no one who can fill his place. There may be specialists in one or another of the old florists' flowers (sacred to me by the memories of a lifetime), but we have no one able to create, foster, and maintain the interest all round as he did. He was the best field officer we had. His aid in counsel and organisation was always sought and always trusted; it was never refused, and never failed. His sanguine hope and cheery spirit, his clear business capacity and foresight, his power of inspiring confidence, and courage in facing difficulties, were all qualities for which we esteemed and loved him in this one cause alone, to say nothing of what he was as a warm-hearted and faithful friend.

Mr. Barlow was familiar with all florists' flowers, both as to their properties and their culture, and if there was one more than another associated with him, it was the Tulip, which he grew for so many successive years at Stakehill—a collection so noted for its wealth of refinement, and into which he gathered the best new Tulips as they appeared among the raisers of the day. There is every hope that the Stakehill Tulips will be kept together, and that at Stakehill still.

As I stood on the summer morning of the closing scene there by the coffin, resting in the dear familiar old room at Stakehill, where with so many cheerful and now vanished faces I have spent numerous happy days and evenings, words rushed back to memory from Thackeray's ballad, "The Mahogany Tree," which we used to read and talk of together:—

\* \* \* \* \*

Life is but short;  
When we are gone  
Let them sing on  
Round the old tree.  
  
Evenings we knew,  
Happy as this,  
Faces we miss  
Pleasant to see,  
Kind hearts and true,  
Gentle and just,  
Peace to your dust!  
We sing round the tree.

Although in health my dear friend had been failing for some time, he fought on, perhaps all too bravely, against the tide and tale of years, and was still so engaged in the activities of a very busy and public life, that the end, coming after all from the effects of an accident, seems to have been sudden and untimely.

So, in a favourite picture in that same room—"The Angel of Death," by G. F. Watts—I could not but see a fresh sad emphasis now. It is full of restful light, and calm, and beauty. But among all the figures grouped round the Solemn Presence, from the little child playing with the Angel's robe to the blind old toothless lion resting at its feet, I thought that one was most symbolic of our dear friend at rest, which shows a strong man in armour, with bowed head, standing before the Angel, and not in fear, but firm obedience, laying his sword upon the altar of the Accepting Angel.—F. D. HORNER.

#### EMBOTHRUM COCCINEUM.

ALTHOUGH introduced many years ago, this beautiful evergreen shrub is seldom seen in gardens, it being apparently not generally known. It may sometimes be met with in gardens in Devonshire, Cornwall, and other south-western counties, also in Ireland; and when

well grown it forms a really beautiful sight. By some persons it has been designated "The Fire Bush," which is expressive as regards the brilliancy of the flowers. These are bright scarlet, and are produced in large sprays, such as that shown in the illustration (fig. 90), which has

aspect, sheltered from north and north-west winds. It is 20 feet high and 30 feet through, and is one mass of fire in colour. We have several other trees ranging from 10 to 20 feet height in bloom. The culture is somewhat difficult. Propagation is effected by seed, cuttings, and layers;

FIG. 90.—EMBOTHRIUM COCCINEUM.

been prepared from a spray sent by Mr. G. Maddeon, gardener to T. B. Bolitho, Esq., M.P., Trewidden, Penzance.

Regarding the specimen from which the spray was cut Mr. Maddeon writes:—"The tree has been planted out twenty years in a south

we have succeeded with them all." From this it will be seen that *Embothrium coccineum* requires a warm sheltered position when planted outdoors, though there is no reason why it should not be grown in lofty conservatories.

## THE DAHLIA.

[A paper read before the members of the Sheffield Floral and Horticultural Society by Mr. M. H. WILLFORD.]

(Concluded from page 485.)

As a support place a strong stake, say 5 feet 6 inches long by 1½ inch square in each hole before planting, so that the roots do not get damaged in driving the stake into the ground, as is very often the case. Some advise watering well at the time of planting; I think this a mistake, for when the soil is in a sodden state the roots do not take to it as quickly as they will to a warm and dryish soil. If the plants droop at all they should be shaded from bright sunshine and the foliage watered with a fine rose. When the plants are established I mulch them with about 3 inches of manure and level the surface, after this they require little else but copious supplies of water, and when water is given it must not be in dribbles, but when you think you have given sufficient just give it as much again, and you will soon see how it is appreciated. Some growers object to top-dressing in the form of a mulching of manure, contending that it causes the roots to come to the surface, so they feed the plants entirely with liquid and chemical manures.

Now comes the question, How much growth is it necessary to let the plant carry? Some advise taking off all the side growths but about three or four, then rubbing off the laterals as they come. I think the results are equally as good by letting the plant make a fair sized bush, taking care that there is no lack of air and light; then, when the plant has made its breaks from the main stem, take off all the laterals that come on the side shoots and you will have plenty of buds to select from, so that if some are deformed or not good enough you have others that are, and when it is decided which to keep you can disbud, and let those selected have the full benefit of the food stored up in the plant.

In growing blooms for exhibition purposes some protection is absolutely necessary. Almost every grower has a way of his own for doing this. Some grow them on boards covered with a flower pot with the bottom knocked out and a piece of glass laid on the top, or a similar contrivance, right from the bud to the mature bloom; others merely shade or shelter them from the sun and rain; others bag them and shade until a few days before they are wanted, then if they are not quite up in the centre they will board them and cover with a pot or bell-glass. A friend of mine uses a contrivance made of four pieces of board with a glass top in two pieces, forming a small span-roofed cover. He finds this to distribute the rays of the sun better than a flat piece of glass, bringing up the centre and keeping the bloom in better shape.

Insect pests should be our next consideration, as the Dahlia is much troubled with these. Snails must be carefully looked for, or they would soon destroy young plants. The earwig or twinge is also very fond of the Dahlia. There are many methods tried to keep the plants clear of these nightly visitants, one of which will spoil in a few hours a flower that has been cared for and watched with interest for a week or more. A few of the methods used are placing hollow sticks, such as elder with the pith picked out, old bean stalks, or what are commonly known as "keeks," amongst the foliage to be used by the earwigs as hiding places. Some use pieces of paper rolled up loosely into a ball for the same purpose, but I think we cannot mend the old-fashioned way of placing a small pot with a little dry grass in it on the top of the stakes, because they are so easily examined. The next pests are the green and black fly. Some folk say if you keep the plants growing they will not be troubled with the fly, but I find if I do not keep watering the foliage and occasionally syringing with soft soap water they will appear, even if the plants are growing freely.

Another insect plague is a kind of microbe which feeds on the young shoots and grows with the plant. There is only one way of getting rid of it that I know of, and that is to dig up the plants that are affected and burn them.

Now, having arrived at the flowering period, I think it will be advisable to look at the much-argued point of dressing the blooms. What constitutes dressing? Where does dressing end and "faking" begin? I think that to get good and perfect blooms, dressing, to a certain extent is necessary, but this can generally be done during the growth of the blooms; when it comes to taking out the centres, seed eyes, and green scale, and placing the petals, then I think it is not fair growing.

After the blooming period comes the question, What are we to do with the tubers? When the first frost has touched the foliage, cut the plants down to 6 inches from the ground, take up the tubers, and lay them upside down under a frame light until they are ripened,

then store them away in a damp and frost-proof place until it is time to start them again. Some growers store their tubers in sawdust, dry sand, and I have heard of them being stored in bran, but it does not matter much how they are stored, so long as they are kept from shrivelling on the one hand and decaying on the other; they will in most cases start into growth when the time comes.

A few of the best varieties are the following (taken from "E. M.'s" analysis of the National Dahlia Society's Shows, published in the *Journal of Horticulture* of March 30th this year), and which may well be repeated for the guidance of purchasers of plants.

*Pompons*.—E. F. Junker, Darkness, White Aster, Favourite, Grace, Isabel, Lady Blanche, Phoebe, Whisper, Gem, Admiration, and Red Indian.

*Cactus*.—Duke of Clarence, Juarezi, Robert Mayher, Marchioness of Bute, Panthea, St. Catherine, Delicata, and Kynarith. The three last named were only sent out in 1892. Of the still newer varieties Countess of Radnor and Bertha Mawley are of sterling merit.

*Decorative Varieties*.—Mrs. Hawkins, Amphion, Empress of India, Honoria, Mrs. Douglas, Black Prince, Charming Bride, and William Darvil. In addition to these you will find that Beauty of Brentwood, Henry Patrick, Asia, Miss Jeykel, Lady Kerrison, and W. T. Aberly are also very good.

*Singles*.—Amos Perry, Miss Henshaw, Victoria, W. C. Harvey, Chilwell Beauty, Duchess of Fife, Florence Fisher, Marion Hood, Miss Roberts, Northern Star, and White Queen.

*Show Dahlias*.—Mrs. Gladstone, William Rawlings, R. T. Rawlings, Harry Keith, Colonist, Mrs. Langtry, William Garrett, James Cocker, Henry Walton, Maud Fellowes, Ethel Britton, and J. T. West.

*Fancy Dahlias*.—Mrs. Saunders, Rev. J. B. M. Camm, Duchess of Albany, Mrs. J. Downie, Frank Pearce, Matthew Campbell, Henry Eckford, Gaiety, Peacock, T. W. Girdlestone, Chorister, and Mrs. N. Halls.

## NOTES ON STRAWBERRIES.

## STRAWBERRY NOBLE.

THIS Strawberry has done uncommonly well with me this year. The blossoms are very susceptible of frost, even before they have opened, but we had no such hindrances this season, and the great piles of enormous fruit, not one large one only, but several to each truss, have been quite a sight to see. They have been a great delight to the poor and sick, who have, with much welcome, shared our abundance. I expect this variety will have a boom this year for market and family use; and, considering its earliness, great size, and huge crop, I think it is, in a favourable season, the finest Strawberry yet raised for—giving away!

For personal use we have contented ourselves with the considerably smaller (but much better flavoured) Vicomtesse Hericart de Thury; that is, as soon as it came in, which was not for quite a week after Noble.—W. R. RAILLEM.

I COMMENCED to gather Strawberries on June 12th (Garibaldi and John Ruskin); the usual time for these varieties to ripen here is the beginning of July. President was gathered five days later. The season will be short, the crop scant, and the fruit small. Our heavy land has stood the drought well, but every day is telling more and more upon it, and unless rain will shortly come all crops will be small in sample and short in bulk.

John Ruskin is not equal to Garibaldi in flavour or texture of flesh. It greatly lacks the melting character of the latter Strawberry. However, it is quite distinct from any variety I have seen, therefore an agreeable change; it is also more uniform in shape than most sorts. I am testing a seedling of my own raising which greatly resembles John Ruskin in berry, but of superior flavour. The fruit is a shade smaller.—G. MCDUGALL, *Ravenna Cottage, Stirling*.

READERS of the *Journal of Horticulture* must have been pleased with the interesting note on Strawberries on page 476. The selection of varieties which Mr. Edward Luckhurst gives is an excellent one throughout, and as he invites criticism and any addition to his list I offer a few notes as to the behaviour of one or two varieties mentioned.

Amongst the earlier kinds Keens' Seedling on our heavy clayey land, however well worked, gives us only a poor return to such varieties as Noble, Sir Joseph Paxton, and Vicomtesse Hericart de Thury. In the case of Noble many will argue that Keens' Seedling is infinitely superior to that as regards flavour. This I admit, but where sugar and cream are used in conjunction with the fruit Noble is one which cannot well be done without, hence I have discarded Keens' Seedling. Another variety which I do not see mentioned amongst the early kinds is Pauline. This with us is a most remarkable cropper, more especially if grown annually, as the plants by some cause soon run out if left more than two years. It is not one of the prettiest fruits, either as regards shape or colour; the hard fluffy lump so often found in the inside of the fruit is a drawback. Dryness at the root often causes this, but if the plants are raised annually, well mulched and supplied with water, a decided

improvement is apparent in the flavour. For those possessing a market garden near a town, where the demand for Strawberries is great, this is a variety worthy to be in any collection. Its great cropping qualities, large size, and firm condition of the fruit are points which cannot be altogether overlooked, more especially if the fruit is to be sent into manufacturing centres.

Amongst the midseason varieties may I add the variety John Powell, which on our land has done wonderfully well for the past three seasons? John Powell is described as "a strong grower and an enormous successional bearer; fruit uneven, but of fine sugary pine flavour, and valuable as succeeding where Queens fail. As grown at Maidstone it is far better than President." This is, to my mind, an excellent description, but with us it is certainly not better than President as regards cropping. However, the growth is very similar to it, the fruit firmer, and one of the highest flavoured I have ever tasted. It is well worth a trial.

Two other varieties which behave with us much the same as Keens' Seedling are British Queen and Dr. Hogg. If your readers, who are successful in cultivating these three varieties, could kindly offer any suggestions as to ground it would be worth while our giving them another trial, for they are certainly the best flavoured of our Strawberries.—R. P. R.

### PECULIARITIES OF APHIS LIFE.

PROBABLY the fact pointed out by Mr. Hiam, page 479, that the Plum aphid (*A. Pruni*, I presume to be his species) will live and propagate itself during an ordinary winter, has been hitherto overlooked both by gardeners and entomologists. It has, however, for some time been known that the older observers were mistaken in supposing that the winter was a period of entire quiescence with the aphid race. Certainly in the great majority of species congress between the sexes occurs in autumn, and batches of eggs are deposited then, the only season when they are produced, these, as a rule, remaining unhatched till spring. Gardeners are familiar with the fact that in houses aphides may be found breeding during the winter months, and at the same season colonies of them are to be detected at the roots of fruit trees and herbaceous garden plants, having descended from the leaves in the autumn to feed where they can be sheltered. Aphides may also be seen upon some evergreens, and on a variety of low plants, such as grasses, in mild winters, but it still remains true that they are chiefly propagated by eggs from one year to the next. It is, I might note, one of the curious circumstances in ant history that these busy workers store up in their hills sometimes the eggs of various species of aphides, as Mr. Buckton and others state, bringing these forth at the spring season and placing them where the young progeny can obtain suitable food.

Mr. Hiam thinks that people generally attach too much importance to the aphid migrations and the influence of "east winds." I presume he does not question that such migrations occur, more particularly in spring and autumn—i.e., about May and September. As the late Mr. Walker pointed out, these migrations are brought on by a change in the atmosphere, a stillness or heaviness in the air occasionally happening when the wind is east, but not always. When such a "blight" occurs the flow of sap in vegetation is checked, aphid food runs short, and the insects appear winged, and travel to another locality. If these journeys are not always long ones they are in some instances. I have had ocular proofs of swarms of aphides travelling from Essex, crossing the Thames where it is nearly a mile wide, to settle on Kentish Hop grounds. Another interesting fact is that aphides not only migrate from place to place, but change their species of plant or tree. That abundant enemy of the Hop, *Aphis Mahaleb*, is known to feed upon Cherry and Plum in the spring. Again, the "dolphin," *A. Fabæ*, and other species, infesting culinary vegetables during summer, migrate from these to species of *Rumex*, Thistles, and other wild plants in the autumn.—ENTOMOLOGIST.

### BEGONIAS AT FOREST HILL.

THE extraordinary improvement that has been made of late years amongst Tuberous Begonias has brought them into the front rank of the florists' flowers. Either for bedding purposes or for growing in pots in greenhouses they are now considered indispensable. To the well known firm of Messrs. J. Laing & Son great credit is due for these developments. They have laboured incessantly with Begonias for several years, and their efforts have been crowned by unqualified success. A visit to their nurseries during the next few weeks will confirm this statement. The houses are literally ablaze with brilliant colours. Everyone should go; those who are interested to become more so, and those who are at present uninterested to be converted, as they must be when they see the magnificent plants carrying their admirably coloured symmetrical blooms.

The plants unquestionably form a spectacle well worth seeing. The single and double flowered varieties are arranged in separate structures, and a short selection from those in bloom on the occasion of my visit will doubtless prove of interest to those unfortunate readers of the *Journal* who are not in a position to go and judge of their beauty for themselves. The impression on entering the house devoted to the single varieties can be but one of intense admiration. The plants are of various sizes, but all bear the unmistakable sign of health in the grand foliage and the fine bold flowers. Duchess of Westminster is one of the most striking varieties in the collection, its crimson blooms having

a clearly defined white centre, are of good form, stand out erectly from the foliage. One cannot help seeing it, and to do so is to admire. One of the most floriferous is Lady Roberts, a pure white with large and substantial flowers. Amongst the dark crimsons, and they are numerous, it would be difficult to find one which has more good points than Mr. William Miller. The blooms are of a medium size, rich in colour, of matchless form, and the habit of the plant cannot be termed anything but perfect. Fringed White denotes a new departure amongst tuberous Begonias. The flowers are pure white and shapely, the petals being fringed at the edges. It is a very beautiful variety. An appropriately named variety is Guardsman, which is clear vermilion-scarlet in colour, the flowers standing boldly erect above the sturdy growths. Lady Mary Lloyd is a very charming salmon coloured variety. Sir J. Blundell Maple is a magnificent scarlet worthy of a place in choice collections.

It is in the double flowered section, however, that one finds the softest and most pleasing tints. The shapely contour of the flowers, more perfect than even the Rose, lacking only the perfume to render them fit and formidable rivals to the queen of flowers. What could one wish to see more beautiful than a plant of Glory of Stanstead? The flowers, which are borne with great freedom, are of a soft pleasing rose tint, slightly paler at the centre. They are of good size, and despite their great weight show very prominently on the plants. It is a variety for which one might confidently predict a great future. Lottie Collins is one of the most distinct in the whole of the collection. The colour is a pure salmon pink, the lower part of the petals which are charmingly fringed taking a slightly lighter shade. It is very floriferous, and the habit of the plant is excellent. Lady Theodore Guest is another very distinct and pleasing form. The colour is difficult to describe in a manner which will convey the best idea of its beauty; pale apricot, slightly flushed and suffused rosy crimson, faintly edged with carmine, is the only description I can give of it. The flowers are large, the petals broad and of very great substance, and the growth of the plant is very fine. Countess of Craven comes as an acquisition, as well as an addition to the pure white varieties. The erect, perfectly double flowers are of great size, and stand out from the leafage in a most striking manner. Earl of Craven is a taking colour, being a rich crimson, the blooms fine, and the variety is very free flowering. Mrs. G. Higgins is a beautiful variety, the colour of which is a soft pleasing yellow. The flowers are of good size, well formed, and the plant of fine habit.

At the time of my visit the beds in the nursery were being filled with tuberous Begonias, and despite the scorching weather they presented a robust and healthy appearance. It is computed that over 300,000 plants will be required to fill these beds, and when they are in flower in August they must present a sight which once seen can never be forgotten.—NOMAD.

### NOTES ON TOMATOES.

IT is natural that disease will at times attack all crops, and this season we, no doubt, may expect to hear of the harmful garden insects being nearly everywhere. In the instance given by your correspondent in the *Journal of Horticulture* of last week, page 471, it would assist him greatly if he fully looked back over his treatment of his Tomatoes from the purchase of the seed, and if in future he follows these rules for growing Tomatoes in pots, I anticipate that next season he will write to you more cheerfully. Young plants should be placed into 3 and 5 or 6-inch pots as soon as necessary, using rather poor soil at this stage of growth. In the final stage clear soot water now and then is invaluable to maintain healthy life in the plants.

The seed should be purchased from one of the best houses in the trade. Sow it very thinly in pans, previously scoured with lime and soft water. Use compost of a good proportion of leaf mould and silver sand, and plenty of drainage. Give only clear rain water. Put into pots in which they are to fruit just before coming into bloom. The pots should be thoroughly scoured with lime before using, and employ clean crocks for drainage. Only half fill the pots at first, reserving the space for an occasional top-dressing.

The soil in the first instance must not contain much manure. If procurable a large portion should be of good sweet old pasture loam with a small amount of leaf mould with a liberal amount of silver sand and charcoal; and add a little thoroughly well decayed stable manure. Turn this all over with a hand fork before using. When top-dressing, and the roots will indicate when this is required, use each time an increased amount of stable manure with the soil. Grow the plants on the single-stem system. Water freely, and give all the ventilation possible during the day without lowering the temperature too much. During such a summer as we are now having a little night ventilation is beneficial, but in ordinary weather I do not give any ventilation to Tomatoes at night. The ventilators are, however, opened very early in the morning.

I have grown Tomatoes in this manner for ten or more seasons, and as yet I have never had a diseased plant or fruit. I grow chiefly the Old Red. This season with other sorts I am giving a trial to Challenger, which is a variety spoken very highly of by the market gardeners round Evesham, and they generally find out the best of everything to grow.

I prefer old cases to pots for Tomato growing, but the drainage must be even more carefully attended to with plants growing in wood. Ten and 11-inch pots are large enough for growing for home consumption.

Twelve-inch pots would be a better size; this must depend upon the size of the house, and the number of plants required.—J. F. D.

My object in writing is to call attention to Mr. Coster's mode of growing Tomatoes at Froyle Park, Alton. He has an exceedingly heavy crop; all the blooms seem to be setting well; the bunches are large, and the fruit very fine in shape and size. I was so struck with the splendid appearance of the crop that I asked for a little information respecting Tomato culture, which should be instructive to growers. I noticed three varieties under cultivation—viz., Earliest of All, Reading Perfection, and Al, but all looked equally well.

The plants are grown in frames, and are tied to bean sticks, which are lodged upon forked sticks, about 6 inches from the glass. An interesting experiment is being tried on the best mode of placing the plants, the results of which, later on, I hope to be able to report. All the plants at the back of the frames are in 48-sized pots, these being sunk in about 6 inches of rich soil. The roots therefore grow over the tops of the pots into the surrounding soil, and ramify accordingly. Mr. Coster says this method prevents excessive growth and favours early fruiting, two of the most essential points for success in Tomato growing. I should certainly say that he is correct in his opinion, although the haulm was very strong and healthy, in some cases as thick as a man's thumb. An equal number of plants at the front of the frames are taken out of the pots and planted in the 6 inches of rich soil, and trained up the stick, so that we have two plants on each stick, one up and the other down, meeting in or about the centre of the frame.

It was really difficult at the present stage to form an opinion as to the relative value of the methods of planting, but the haulm in the latter case seemed much riper, and the lower leaves were very spotty, as if they had completed their work. If we can obtain an account of the weight of fruit in each case we shall have gained some useful information.

Mr. Coster believes in plenty of air and very little moisture among the leaves. The lights are open for the greater portion of the day, which keeps the haulm clear of insects. No water is allowed to touch the foliage, and very little has as yet been given to the plants. The syringe for Tomato growing is, he says, quite out of the question. Altogether this mode of cultivation has much to recommend it, for the shoots are readily tied, the fruit is well supported, it ripens well, and is easily gathered. The frames in this case had been used for early Strawberries, and this is the first trial of Tomatoes in them.

One remark may prove interesting about the setting of the blooms. Every day Mr. Coster (generally about midday) shakes each stick lightly, and he finds this is almost a certain mode of shedding the pollen and securing complete fertilisation. There is at present no sign of fungoid disease upon the plants.—EDWARD H. SMITH, *Warminster*.

## ROYAL HORTICULTURAL SOCIETY.

JUNE 20TH.

THE Drill Hall was well filled on this occasion, and there was a good attendance. Orchids were not so extensively shown as is sometimes the case, but hardy flowers were well represented. Roses formed the principal feature, this being the National Rose Society's first exhibition of the year, a report of which appears elsewhere in this issue. Some fruit was shown, as will be seen by the remarks below.

**FRUIT COMMITTEE.**—Present: Philip Crowley, Esq. (in the chair), Dr. Hogg, Messrs. T. F. Rivers, G. W. Cummins, G. Taber, A. Dean, G. H. Sage, G. Wythes, J. Hudson, and H. Balderson.

Messrs. J. Veitch & Sons sent twelve varieties of Cherries gathered from pyramid trees in the open air. The fruit was well ripened, and amongst other varieties shown were Royal Duke, Knight's Black Early, Mammoth, May Duke, Black Hawk, Governor Wood, Nouvelle Royale (cultural commendation). Mr. W. Allen, Gunton Park Gardens, sent fruits of Lord Suffield, Gunton Park, and Empress of India Strawberries. They were all good flavoured (vote of thanks). Mr. Richard Parker, Impney Gardens, Droitwich, sent six Queen Pines, well grown fruits (silver Banksian medal). Mr. E. Beckett, Aldenham House Gardens, Elstree, also sent six grand Queen Pines, and a silver Banksian medal was recommended. Messrs. T. Rivers & Son, Sawbridge-worth, had well coloured fruits of Alexander, Waterloo, and Amsden June Peaches, all ripened in a cold orchard house (vote of thanks).

Several seedling Melons were shown, these coming principally from Mr. H. J. Easty, The Prospect, Sudbury; Mr. C. Brooke, The Gardens, Red Rice, Andover; Mr. A. Bishop, Westley Hall Gardens, Bury St. Edmunds; Mr. B. Ashton, Glossop Hall Gardens; but no awards were made, the fruit in some instances being of rather poor flavour. Mr. J. Douglas, Great Gearies, sent a seedling white Grape, the result of a cross between Black Hamburg and White Muscadine. The berries are medium size, and have a sweet Hamburg flavour. Messrs. H. Cannell & Sons, Swanley, sent a basket of George Rundle Strawberry, a brisk flavoured variety, but no award was made. Robert Mackellar, Esq., Abney Hall, Cheadle, sent a basket of fine President Strawberries, also a bunch of Oranges (vote of thanks). J. Watson, Esq., Berwick House, Shrewsbury, had fruits of Musa Cavendishi (cultural commendation).

Mr. Owen Thomas, The Royal Gardens, Frogmore, sent twelve punnets of Strawberries and the same number of Cherries, for which a silver Banksian medal was recommended. The Strawberries were very fine, especially Noble, James Veitch, Sir Joseph Paxton, The Countess,

Waterloo, and Aromatic. Dr. Kirby, Kelsey Park, Beckenham (gardener, Mr. Mark Webster), sent clusters of Sutton's Al Tomato; and P. Crowley, Esq., had specimens of dried Asparagus, also some in a cooked condition, showing that this vegetable can be preserved in this manner for future use.

**FLORAL COMMITTEE.**—Present: W. Marshall, Esq. (in the chair), Rev. H. H. D'Ombraim, Messrs. J. Fraser, W. H. Williams, H. Herbst, H. Bevan, G. Stevens, T. Godfrey, C. T. Bause, F. Ross, C. J. Salter, J. D. Pawle, P. Barr, W. Furze, W. Bennet-Poë, J. Walker, C. E. Shea, T. Baines, G. Gordon, G. Paul, T. W. Girdlestone, R. Owen, and J. Jennings.

Messrs. P. Barr & Son, King Street, Covent Garden, arranged an excellent collection of hardy flowers, prominent amongst which were Delphiniums in variety, Eryngium giganteum, Irises, Alströmerias, Lilliums, and Hemerocallis (silver Flora medal). Messrs. E. D. Shuttleworth, Peckham Rye, S.E., staged a collection of hardy flowers, amongst which some fine Delphiniums were very noticeable. The exhibit also included Pinks, Lilliums, Gladioli, Gaillardias, and some charming Roses (silver Flora medal). The same firm also staged a magnificent group of flowering and foliage plants, including Caladiums, Lilliums, Hydrangeas, Ferns, Palms, and Orchids (silver Flora medal). Messrs. J. Laing & Son, Forest Hill, staged a group of ornamental foliaged Tuberous Begonias, and a few double varieties. The former produced an excellent effect, rivalling the well-known Rex varieties in beauty of their leafage. The best of the double Begonias in this stand were Farini, Countess of Craven, and John Fraser. Awards of merit were adjudged for the two last-named, which are described elsewhere. Mr. J. Perry, gardener to J. C. Tasker, Esq., Middleton Hall, Brentwood, again showed a bright collection of Cannas and cut Roses. Messrs. F. Sander & Co., St. Albans, staged a fine plant of Aristolochia gigas var. Sturtevantii in flower, and also a plant of Maranta Leonia. Messrs. J. Veitch & Sons, Royal Exotic Nursery, Chelsea, had some fine baskets of hardy shrubs, notably Notospartium Carmichaeliae, Escallonia Philippii, and Andromeda speciosa cussinefolia.

Mr. Chas. Turner, Royal Nurseries, Slough, staged a grand group of Carnations, including Souvenir de la Malmaison in excellent form, and the fine Germania and Crimson Rambler Rose (silver Banksian medal). E. Herbert Fison, Esq., Stoke House, Ipswich, had a collection of flowering plants and Ferns which had been sent from New Zealand frozen in ice. The collection included Sprekelia formosissima, Asplenium lucidum, A. falcatum, Lomaria filiformis, Callistemon, Leptospermum scoparium, L. ericoides, Carpodetus serratum, Hedycarya dentata, Statice, and Clematis. Mr. E. C. Goble, Ryde, showed some Carnation blooms which had been cut from plants growing in the open border. Messrs. G. Paul & Son, The Old Nurseries, Cheshunt, sent two boxes of Her Majesty Rose in excellent condition, and also blooms of Paul's Early Blush and Charles Gater (silver Banksian medal). C. J. Grahame, Esq., Croydon, sent two boxes of Roses, fresh and beautiful, and for which a bronze medal was recommended. A. H. Gray, Esq., Newbridge, Bath, sent sprays of a seedling Climbing Rose named Allister Stella Gray. An award of merit was adjudged for this variety. Messrs. W. Paul & Son, Waltham Cross, sent a box of Roses Spenser and Clío, for which a silver medal was recommended.

Mr. Moore, Botanic Gardens, Glasnevin, sent flowers of Crinum Powelli alba, for which a first-class certificate was awarded. Other flowers also came from the same source, but no further awards were made. R. Smith, Esq., Hayes Common, Beckenham (gardener, Mr. C. Blick), secured awards of merit for Carnations Hayes' Scarlet and King Arthur. These are described elsewhere. G. F. Wilson, Esq., Weybridge, sent some charming forms of Calochorti, and two of these were deemed worthy of awards of merit. They are described below. Mr. C. G. Van Tubergen also sent some Calochorti, and awards of merit were adjudged for C. venustus oculatus, C. v. roseus, and C. v. Vesta which are described elsewhere. J. Brutton, Esq., Yeovil (gardener, Mr. A. Crossman), secured the first prize for twelve Delphinium spikes.

**ORCHID COMMITTEE.**—Present: H. J. Veitch, Esq. (in the chair), Dr. Masters, Messrs. J. O'Brien, W. H. White, J. Douglas, T. Statter, R. Brooman-White, C. J. Lucas, H. M. Pollett, De B. Crawshay, A. H. Smee, H. Williams, T. B. Haywood, and E. Handley.

Messrs. B. S. Williams & Son, Upper Holloway, N., sent a grand group of Orchids tastefully arranged, and for which a silver Flora medal was recommended. Conspicuous amongst others in this contribution were some fine plants of Epidendrum vitellinum majus, which made a fine display amongst the Cattleyas, Oncidiums, and Odontoglossums. The beautiful Dendrobium Deari, Cypripedium grande, and Cattleya Wagneri were also noticeable in this group. Sir Trevor Lawrence, Bart., Burford Lodge, Dorking (grower, Mr. W. H. White), sent Coelogyne sulphurea, a small flowered species; Lælia crispilabia variety, an exceedingly pretty little flower; Lousica vulcris and L. Amesiana (botanical certificates); and Phaius Humbloti, a charming species with spikes of pale pink flowers. T. Statter, Esq., Stand Hall, Manchester, exhibited a spike of Cypripedium Aylingi bearing two flowers. A statement shown with the blooms was to the effect that "the first flower on this spike was exhibited at the recent Manchester Orchid Show, and was awarded the Veitch Memorial medal and a prize for the best hybrid in commerce." It is a pretty flower, the lip being ivory white, the dorsal sepal and petals veined and spotted purplish crimson. Messrs. Charlesworth, Shuttleworth, & Co., Heaton, Bradford, sent a plant of Odontoglossum peruvienne (botanical certificate). Norman C. Cookson, Esq., Oakwood, Wylam-on-Tyne, sent a spike of Selenipedium caudatum Wallisi, and Cypripedium hybridum, a pretty hybrid. Messrs.

James Backhouse & Sons, The Nurseries, York, sent a pan of seedling Disa, the result of a cross between *D. racemosa* and *D. grandiflora*. A spike of *Aërides virens* came from the Royal Botanic Gardens, Dublin, and *Cypripedium Psyche* from Mr. Charles Winn, Birmingham.

Messrs. Hugh Low & Co., Upper Clapton, sent a small group of *Cattleyas* and other Orchids, for which a silver Banksian medal was recommended. *Cattleya gigas Sanderiana* and some good forms of *C. Mossiae* were noticeable in this group, as also was the pretty *C. Harrisoniae*. Messrs. W. L. Lewis & Co., Southgate, N., had a group of *Cattleyas*, *Oncidiums*, *Cypripediums*, and *Odontoglossums* arranged with Ferns and other foliaged plants (bronze medal). Messrs. F. Sander and Co., St. Albans, sent a group of choice species and varieties. The best of these included *Odontoglossum vexillarium* var. *superbum*, *O. Uro-Skinneri*, the beautiful *Cattleya granulosa*, *Sobralia xantholeuca*, *Pescatorea Klabochorum*, the magnificent *Cattleya Warscewiczii* var. *Sanderæ* (award of merit) *Dendrochilum filiforme*, and *Epidendrum Fortgetianum*, for which botanical certificates were awarded. M. Wells, Esq., Broomfield, Sale (gardener, Mr. R. Hinds), sent a number of cut Orchid blooms, including the charming *Cattleya Mendeli delicata*.

#### CERTIFICATES AND AWARDS OF MERIT.

*Begonia Countess of Craven* (J. Laing & Sons).—A white double variety with a faint tinge of green in the centre of the flower (award of merit).

*Begonia John Fraser* (J. Laing & Sons).—A fine double variety with rich crimson scarlet flowers (award of merit).

*Calochortus venustus oculus* (G. F. Wilson and C. G. Van Tubergen, jun.).—The flowers of this variety are large creamy white, each petal being evenly marked with yellow and brown at the base (award of merit).

*Calochortus venustus roseus* (G. F. Wilson and C. G. Van Tubergen, jun.).—This is a splendid variety with large flowers. The petals are rose tinted, have a reddish blotch in the centre, and are very prettily marked at the base (award of merit).

*Calochortus venustus Vesta* (C. G. Van Tubergen, jun.).—A pretty variety with creamy white petals, pale yellow at the base, and blotched dark brown (award of merit).

*Carnation Hayes' Scarlet* (R. Smith).—A splendid border variety. The flowers are large and of great substance (award of merit).

*Carnation King Arthur* (R. Smith).—This is a useful border variety with large dark red flowers (award of merit).

*Cattleya Warscewiczii* var. *Sanderæ* (F. Sander & Co.).—This is a magnificent form. The sepals and petals are bright rosy mauve, the latter being broad with fimbriated edges. The lip also is large, bright purplish crimson, and lighter edge, with orange yellow spots in the throat (award of merit).

*Crinum Powellii alba* (F. Moore, Botanic Gardens, Glasnevin).—A splendid form with large pure white flowers, strongly scented (first-class certificate).

*Gloxinia Princess May* (J. Laing & Sons).—A grand variety with pure white erect flowers of great substance (award of merit).

*Rose Allister Stella Gray* (A. H. Gray).—This is a climbing Rose. The flowers are rather small, buff coloured, and borne in clusters (award of merit).

*Rose Mrs. Harkness* (Harkness & Son).—This is a Hybrid Perpetual of some promise. The flowers are medium sized, good form, and resembling Her Majesty in colour, but rather lighter (award of merit).

*Rose Merrie England* (Harkness & Son).—A striped Rose of good shape, the flowers having a full centre (award of merit).

#### A VISIT TO TRENTHAM.

IN accordance with a kind invitation from the Duchess of Sutherland I recently paid a visit to Trentham, on my way home from London. In front of the house, which is quite palatial in aspect, are magnificent statues and fountains, rising from a perfect paradise of gardens, everywhere glowing with Azaleas and Rhododendrons and beautiful flowering trees, all of which at the period of my visit were in perfect bloom. An exquisite lake, in the centre of which is a wooded island, terminates the prospect from the window of the conservatory, which could not easily be surpassed. The nearest approximation to Trentham in Scotland, so far as my experience is concerned, is Floors Castle, near Kelso.

It has already been mentioned in the *Journal* that the Duchess of Sutherland is an assiduous cultivator of Eastern Lilies; I was not, therefore, surprised to find Mr. Blair, the head gardener, has of late devoted great attention, with most gratifying results, to the cultivation of these. There are such splendid varieties as *Lilium giganteum cordifolium*, *longiflorum Harrisii*, *speciosum*, *rubrum*, *album*, *roseum*, and *Krætzerei*, *umbellatum* and *Krameri*, *Wallacei* and *Martagon*. To me they were most interesting, for last October I had the pleasure of recommending those varieties.

But Orchids form the prevailing attraction at Trentham, where in houses specially adapted to these superb plants, they grow and bloom magnificently. I found the *Cattleyas*, *Lælias*, and *Dendrobiums* especially attractive. I was also much charmed with the Trentham Carnations, of which the finest were *Souvenir de la Malmaison* and *Mrs. Muir*, the latter a pure white variety of perfect form and matchless fragrance.

Roses do not grow well in Staffordshire, for which reason they are chiefly cultivated by the Duchess at her Lilieshall residence near

Newport in Shropshire, where a Rose garden has been recently established. There they have probably a purer atmosphere and a more congenial soil.—DAVID R. WILLIAMSON.

#### HABERLEA RHODOPENSIS.

ALTHOUGH by no means a new plant, having been introduced in 1880, *Haberlea rhodopensis* is seldom seen in gardens. It is dwarf, resembling a *Ramondia* in habit, but with somewhat funnel-shaped flowers, 1 inch long, like a small *Streptocarpus*, the tube purple, and five white lobes. They are borne in trusses of three or four flowers each, arising from amongst the foliage. *Haberlea rhodopensis* is a native of Macedonia, and is closely related to the two genera mentioned above. In Decandolle's "Prodromus" it is placed in the

FIG. 91.—HABERLEA RHODOPENSIS.

family Cyrtandraceæ, between *Ramondia* and *Conandron*, both monotypic genera, *R. pyrenaica* and *C. ramondiioides* being well-known garden plants.

#### THE GREAT YORK GALA.

JUNE 14TH, 15TH, AND 16TH.

ONE of the disadvantages of a first visit to a show of old standing, writes our special correspondent at York, is the impossibility of replying to the question which everybody asks, and that is, how the Exhibition compares with its predecessors. If you frankly confess you do not know, because you have never been before, you receive a stare that is one of incredulity if not of pity, and of pity if not of incredulity. In the minds of York people and those living in other parts of the county all that is highest and best in the way of floral displays is that which has been held for thirty-five years in the old Cathedral city, and not to see it as it comes round season after season is to miss the great event of the year. It is not a function of the ordinary kind. There is not a committee of gardeners to get together in solemn conclave and make the essence of their deliberations the decision of some such knotty point as whether there should be two classes for Coleuses, or whether there should be one only, or whether there should be none at all. But a body of business

men, including many leading lights of the City Corporation, bring their energies to bear. They put matters on a broad and popular basis, and ally with the Exhibition a long and varied course of entertainments. They have had their reward. At Gala time quiet York hardly knows itself. Visitors pour in from far and near and crowd into the show grounds in thousands. No matter whether it is the fruit or the fireworks, the bouquets or the balloon, the Irises or the feats of strength which attract them, they come, and that is the main thing. There are plants and popularity, flowers and fun, and so the York Gala goes on its way prosperous and rejoicing.

A mistake that might be made in some cases would be to consider that the Show might be treated as a minor consideration, that anything in the way of horticultural products would suffice. It is not made at York. The Exhibition is the leading feature, and the other things are accessories. A most extensive schedule is compiled, and several hundred pounds given in prizes. One class for groups absorbs £58, and the first fruit class takes £25. This means prizes worth striving for by the leading cultivators, and consequently the exhibits are of the first quality. Common report and the testimony of experts characterised this year's Show as one of the best, if not the very best, yet held. Certainly there was much both to astonish and delight a new visitor. Take the case of the groups. They were totally distinct from the common order, more tasteful, more complete. That of Mr. McIntyre, which won the first prize of £20, was really a work of art, as carefully thought out, as boldly limned, and as exquisitely finished as a great painting. There is the soul of a true artist in the man, unknown to the present writer, who designed and executed this marvellous group, and as much respect ought to be felt for him as for a Tadema or a Millais. The specimen plants must be placed in a different sphere, for their chief qualification is bulk; nevertheless, as examples of culture they were remarkable. Mr. Cypher, Mr. Letts, Mr. Nicholas, Mr. Leadbetter, and others brought out some of the wonderful giants with which their names are associated, and very striking they were in their huge proportions and fine colours. The Pelargoniums, too, made a surprising display. They nearly filled one large tent, forming two immense banks ablaze with all the hues these robust plants possess. Very rarely are such examples met with as those which Mr. Vear, Mr. Eastwood, and Mr. McIntosh exhibited. The foliage and bloom were extremely fine, and they were allied to great size of plant and admirable training. It would be impossible to comment specially on all the things worth special mention, but it may be added that the cut flowers were a splendid feature, and that fruit was very finely shown, Mr. McIndoe's win in the leading class being gained by material of sterling quality.

It might be expected that the experience of thirty-five years would teach valuable lessons in the way of arrangement, and certainly there is little to take exception to. The disposal of the tents, the allotment of space for exhibits, the judging, and the countless details connected with such a gigantic undertaking were effected in a satisfactory manner. Alderman Sir Joseph Terry, Mr. Alderman Milward, and the Secretary, Mr. Simmons, worked with praiseworthy coolness, and so matters went smoothly on. They were all valuable helpers, and the Gala owes much to them. The Lord Mayor (Mr. Alderman Close), an amateur gardener of great earnestness, also takes a deep interest in the undertaking, and actively supports it. Judging by his speech at the luncheon age has neither quenched his love for gardening nor dimmed his wit. It was claimed for him that he might fairly be termed an ancient York florist, for he had cultivated Dahlias sixty years ago. The collation brought together a most pleasant gathering of northern horticulturists. Glorious weather favoured the Gala throughout, and all went merrily as a marriage bell. The total number of visitors last week were 52,915, an increase of 12,400 over that of last year, and 3169 more than in 1890, the highest number on record until this year.

#### GROUPS.

The groups were to consist of "miscellaneous plants arranged and banked for effect, and occupying a space not exceeding 300 square feet." This afforded good scope, and as prizes of £20, £15, £10, £8, and £5 were offered it was not surprising that one of the six large tents was fully occupied. It is difficult to imagine that the art of grouping has been carried to higher excellence than at York. Two of the arrangements can only be justly characterised as magnificent, while a third, though less original, was very beautiful. The valuable first prize went to a superb group arranged by Mr. McIntyre, gardener to Mrs. Pease, which was beautifully designed and admirably worked out. So complete and elaborate was it that a description cannot do it justice. The centre was occupied by a large mound of stones covered at the base with Ferns, Cattleyas, and other flowers pushing through. Above was a bright, but not heavy mixture of Crotons, together with various Orchids and other flowers, a graceful Palm surmounting the whole. In a line with this at each end was another smaller mound somewhat similarly planted. In front of these three mounds were two lower ones arranged so as to form with the larger a pair of triangles; a line of Ferns, Palms, Caladiums, and other plants formed a beautiful background, and in front was a broad border or low bank of Ferns, Caladiums, Crotons, Dracenas, Orchids, and other foliage and flowering plants. There was no crowding, each mound had a broad base or groundwork, and the plants were disposed with faultless taste. Clearly Mr. McIntyre is a master in plant arrangement. If there was an academy of garden artists he would soon be admitted.

Another very beautiful group was put together by Mr. Edmonds, gardener to the Duke of St. Albans. Broadly speaking, it consisted of a series of mounds and recesses, the arrangement being graceful, free,

informal, and extremely beautiful. It was full of bright flowers and cool foliage. In the ordinary course of events such a group would have scored an easy victory; but though defeated Mr. Edmonds secured a handsome prize as a reward for the care and taste which he had displayed. The third prize went to Mr. W. H. Simpson, whose group was full of good material tastefully arranged, but displaying less originality of design than the others, and if anything a little heavy. Mr. Semley was fourth, and Mr. Stephenson fifth. Mr. Letts, gardener to the Earl of Zetland, Aske Hall, secured the first prize of £20 for a group of ten stove and greenhouse plants in bloom (Orchids excluded), and six ornamental foliaged plants, with some magnificent specimens. Croton angustifolius was a noble plant 6 feet high and through; Azaleas Cedonulli and Criterion were splendidly flowered plants about 6 feet by 6. Erica depressa was about 7 feet across and full of bloom; and there was a fine plant of Anthurium Schertzerianum, together with a superb Kentia Forsteriana about 12 feet high. Mr. J. Cypher was a good second with some excellent specimens, such as Pimelea diosmæfolia 6 feet across, Erica ventricosa hirsuta alba of equal dimensions, Latania borbonica 20 feet high, and a grand Bougainvillea glabra. Mr. J. F. Mould was third.

#### SPECIMEN PLANTS.

Mr. Cypher was first with six stove and greenhouse plants in bloom, Orchids excluded, exhibiting a most powerful contingent. He had Phœnocomma prolifera Barnesi, 5 to 6 feet across and full of bloom; Erica Cavendishiana, 7 to 8 feet; E. ferruginea major, Hedaroma tulipifera, 6 to 7 feet; Ixora Williamsi, and a good Dracophyllum gracile. Mr. Mould was second with a grand Phœnocomma, larger than Mr. Cypher's, but hardly so full of bloom perhaps; Erica tricolor Wilsoni, 7 feet through; a fine Statice profusa, and other good plants. Mr. Nicholas, gardener to the Earl of Zetland, Upleatham, was third with Erica Cavendishiana and Dracophyllum gracile in excellent condition. Mr. Nicholas was first with three plants, these including a splendid Ixora Pilgrimi. Mr. Haw, gardener to Mrs. Lloyd, second with a fine Bougainvillea amongst his trio; and Mr. J. P. Leadbetter, gardener to A. Wilson, Esq., third. Mr. Slater, gardener to the Lord Mayor of York, was first with one plant, a very healthy and well flowered Stephanotis floribunda on a balloon shaped trellis representing him. Mr. Letts was second, and Mr. McIntyre third. In the corresponding class for a greenhouse plant Mr. Letts was successful with Apelexis macrantha rosea beautifully bloomed. Mr. Atkinson, gardener to F. Schröder, Esq., second; and Mr. Rollinson, gardener to W. Bateman, Esq., third.

For six ornamental foliage plants Mr. Letts was first, his contribution including a magnificent Croton montefontainensis, 7 to 8 feet through, and splendidly coloured; a fine Cycas revoluta, and Kentia Forsteriana and australis of considerable dimensions. Mr. McIntyre was second, Cycas revoluta, Crotons angustifolius and Queen Victoria 7 to 8 feet across being his best plants. Mr. Sunley and Mr. Simpson secured the remaining awards. Mr. Leadbetter won with three plants, Messrs. Nicholas and McIntyre following; and in the class for two plants (amateurs) the awards went to Messrs. Rollinson, Leadbetter, and Letts, in the order of their names. Mr. Letts was the only exhibitor of three greenhouse Azaleas, and was placed first for huge, informal plants well flowered. Mr. Cypher was successful with one plant. Mr. Letts was to the front with four Crotons. He had a magnificently coloured Queen Victoria about 7 feet through, and a very fine Chelsoni. Mr. McIntyre was second. The latter was victorious with four Dracenas, showing large and well coloured plants. Mr. Leadbetter was second, and Mr. Smallwood, gardener to H. Leatham, Esq., third. The best three Cape Heaths came from Mr. Cypher, Jubata rubra, Kingstoniensis, and Massoni major representing him. Mr. Mould was second. Messrs. Atkinson; F. Young, gardener to T. F. Wood, Esq.; and W. Dodds, gardener to the Hon. C. Lambton, took the prizes for Coleuses. Messrs. E. D. Shuttleworth & Co.'s prizes for Palms and fine-foliaged plants were won by Mr. Sunley and Mr. Simpson.

#### FERNS.

Ferns are admirably grown in the north, and many fine plants were exhibited. Mr. Nicholas was first with six exotics, having Davallia fijiensis plumosa 7 to 8 feet across, D. tenuifolia Veitchi of nearly equal dimensions, Leucostegia immersa about 6 feet, Lomaria zamiaefolia, Sadleria cyatheoides, and Gleichenia Mendeli, 6 feet through. Mr. McIntyre was second with Dicksonia antarctica, Davallia fijiensis plumosa, and Gleichenia Mendeli of fine proportions and health; and Mr. Snowden, gardener to the Rev. G. Yeates, third. Mr. Leadbetter won with three, having splendid plants of Leucostegia immersa, Microlepia hirta cristata, and Gleichenia dicarpa. Messrs. McIntyre and Lazenby, gardener to H. Bushell, Esq., were second and third. The best single specimen came from Mr. Rollinson, who had a splendid Gleichenia rupestris glaucescens 6 feet across, Messrs. Smallwood and Leadbetter following. Mr. Nicholas had the finest Tree Fern, a very fine Dicksonia antarctica; and the next best plants came from Messrs. Simpson and Eastwood. Hardy Ferns were also well shown, and the collections were of great interest to lovers of this class. Mr. J. Nicholson won with ten plants, one of them being an Athyrium filix-fœmina Howardianum, 6 feet across; Messrs. J. Jackson and Simpson following. With six, Mr. Jackson won from Messrs. Nicholson and Snowden. The best single specimen came from Mr. Nicholas, this being a Trichomanes radicans, nearly filling a 4 feet case. Mr. W. Heppell was second, and Mr. Lazenby third.

#### ORCHIDS AND OTHER FLOWERING PLANTS.

For ten Orchids £22 was offered in four prizes. The premier award went to Mr. Cypher for even healthy and well flowered pieces of Lælia

purpurata, Cattleya Mossiae, C. Mendeli, Dendrobium suavisimum, Anguloa Ruckeri, Thunia Marshalli, Oncidium macranthum, and three others. Mr. W. Holmes, gardener to W. Hardy, Esq., was a close second with some excellent plants, a large Cymbidium Lowianum, a good Dendrobium Dearei, and Cattleya Warneri in fine condition, being amongst them. Mr. Rollinson was third, and Mr. Sunley fourth. Mr. Holmes won with six, even healthy plants full of bloom representing him. Messrs. Cypher and Sunley followed. Messrs. Holmes and Slater were first and second with four plants, and Messrs. Cypher and Holmes second and third with three. Mr. W. Church, gardener to P. Thelluson, Esq., was first for one plant, exhibiting a beautiful Cattleya gigas with fourteen grand flowers in perfect condition. Messrs. Nicholas and Eastwood were second and third. Gloxinias were a splendid display, the principal exhibitors being Messrs. Guest (gardener to C. B. Lamb, Esq.), R. Pearson (gardener to J. Bellerby, Esq.), Dawe (gardener to Dr. Pierce), and Atkinson. Alpine and herbaceous plants were very beautiful; twenty plants were asked for, and Mr. J. A. Rodwell was first with a grand collection. He had a pan of the pretty rosy lavender Dianthus fimbriatus nearly 2 feet across, Silene saxatile, Artemisia vulgaris variegata, and other good plants. Mr. S. Hardcastle was second, and Mr. G. Hudson third, both exhibiting Mrs. Sinkins Pink. Pelargoniums were superb. Messrs. Eastwood and McIntosh have generally had hard struggles for first place, but on this occasion they were both beaten in this class for twelve Shows by Mr. J. Vear, gardener to Miss Steward. He had splendid, healthy, well trained plants full of flower. Mrs. Morrison, Duchess of Teck, and Rose Celestial were about 4 feet across, and others 3 to 4 feet. Mr. Eastwood was second with Madame Thibaut and Madame Hilaire, 3 to 4 feet across, and Kingston Beauty, 4 feet, the others being smaller. Mr. R. McIntosh, gardener to J. T. Kingston, Esq., was third. Mr. Vear won again with six, the plants being smaller than the others but in perfect condition, and the second and third prizes were again won by Messrs. Eastwood and McIntosh. The order was exactly reversed in the class for three. Mr. H. Pybus has some splendid Zonals and Nougays, winning easily in the leading class. He had Sir H. Stanborough and Mrs. Kelley upwards of 5 feet across, with Mrs. Turner and Mulberry closely approaching them, all full of bloom. Messrs. Eastwood and Vear secured the remaining awards. Mr. Eastwood was first for six, the second and third prizes being withheld. Mrs. Tetley's skilful gardener also won with three, Mr. Vear being his most dangerous opponent, and again with eight doubles, these being grand plants. Messrs. Cottam, jun., and Simpson were second and third. With four plants the struggle for premier honours once more lay between Messrs. Eastwood and Vear, the former winning. Ivy-leaved were splendidly shown by Mr. Pybus, who had large pyramidal plants with ample foliage and abundance of bloom. La Florifere was a grand plant. Messrs. Cottam, Eastwood and McIntosh accounted for the remaining prizes, while in the class for three Messrs. Leadbetter and McIntosh were second and third. The best Tuberous Begonias came from Messrs. Bailey and Co., the best Calceolarias from Mr. Guest, the best Fuchsias from Messrs. Simpson and Clarke, and the best Lilliums from Mr. Eastwood. Mr. McIndoe won with table plants, Messrs. Rollinson, McIndoe and Snowden following.

#### ROSES AND OTHER CUT FLOWERS.

This is an early season, but June 14th was somewhat too early to look for a high class display of Roses. Surprising to relate, three exhibitors had managed to get stands of seventy-two together, but naturally they were only of moderate quality. Mr. May of Bedale was first, Messrs. Harkness & Son of the same place second, and Mr. G. Mount of Canterbury third. The first named had Marie Baumann, Mrs. J. Laing, Comtesse de Ludre, and Queen of Queens in good condition. Mr. Mount won with forty-eight, Ulrich Brunner, Souvenir d'Elise, Madame G. Luizet, and Mrs. J. Laing being his best flowers. Mr. May was second. With thirty-six Messrs. Mount and Jackson & Co. were first and second, while with twenty-four Mr. E. B. Lindell was victorious, he having Lady Mary Fitzwilliam, Madame G. Luizet, Souvenir d'Elise, and Viscountess Folkestone in excellent trim. He won again with eighteen, and with another eighteen in the amateurs' class, having good flowers in both. The Rev. F. R. Burnside was first with twelve white and yellow blooms, the Hon. Edith Gifford and Marie Van Houtte being very good indeed. Mr. Mount was second, and Mr. May third. Mr. Burnside also won with twelve Teas of one variety, having an admirable stand of Innocente Pirola, the other prizes going to Messrs. Mount and May. A third victory fell to the famous grower of Teas in the class for twelve blooms, this being one of the best stands in the Show, and a fourth in that for six. Plants in pots were best shown by Messrs. Pybus, W. Jackson & Co., Eastwood, Church, Vear, and J. Hume.

Cut flowers generally were extensively shown, but space cannot be found for details of the awards. Pyrethrums as exhibited by the leading prizewinners, Messrs. Hutchinson and Harkness, were very fine. Messrs. Ware's prizes for herbaceous flowers were won by Messrs. Harkness, Hutchinson, and Riddell; those of the Committee by Messrs. Harkness, McIndoe, Riddell, and Hutchinson. Show Pelargoniums from Mr. Holmes were good, Carnations and Picotees from Messrs. M. Campbell, H. Clark & Son, Fletcher and Archer, fair. The Lord Mayor gave the prizes for the latter, and does well to encourage the culture of such beautiful flowers, but it was too early for them. Mr. Letts was first with twelve stove and greenhouse flowers, Mr. McIndoe second, and Mr. Cottam third, while in another class from which Orchids were excluded the winners were Messrs. Nicholas, Cottam, and How. Mr. McIndoe won with six, and Mr. Colchester's prize for nine was secured

by Mr. Cottam. Mr. Cypher was first for a vase with a light and beautiful arrangement, Messrs. Lunt, Edmundson, and Webster following. The skill of Messrs. Perkins & Son was well shown in the bouquet classes, for they were first with bridal, ball, and hand bouquets, scoring another victory with a hand basket. Mr. Edmundson also showed very creditably. Pansies and Violas made a charming display. Mr. A. Bailey, jun., was first with forty-eight Fancy Pansies, and also with twenty-four, exhibiting large, substantial, and fresh flowers. The second and third prizes went to Messrs. J. Smellie, Paul & Co. (Bridge of Weir), and A. Lester. Mr. Smellie was first with twenty-four Shows, having a beautifully smooth and even stand; Mr. Lister was second. In the amateurs' class for twenty-four Fancies the prizes went to Messrs. Mann, Archer, and Mitchell in the order of their names; and in that for twelve, to Messrs. Thornton (who had grand flowers), Hall, and Illingworth. Mr. Thornton also won with twelve Shows; while in the special class for twenty-four Fancies Mr. Mann was victorious with a beautiful stand. There was one class for Violas, twenty-four sprays being asked for. Mr. John Smellie was first with a delightful stand, including the new seedling Mahogany, to which a certificate of merit was awarded. Messrs. Paul & Co. were second, and Mr. Hutchinson third.

#### FRUIT AND VEGETABLES.

There was an extensive and excellent display of fruit. The principal class was for ten distinct varieties, and Mr. J. McIndoe was successful with a splendid collection, containing Black Hamburg Grapes, good but not perfectly coloured; Musa Cavendishi, fair Foster's Seedling Grapes, good Early Transparent Gage Plums, fine Goshawk and Violette Hative Peaches, Stanwick Elruge Nectarines, Brown Turkey Figs, a fine Highcross Hybrid Melon, and a good Queen Pine. Mr. R. Parker, gardener to J. Corbett, Esq., was second with good Grapes and Figs and a splendid dish of Dr. Hogg Strawberries. Mr. Edmunds was third. Mr. Bannerman, gardener to Lord Bagot, came to the front with six varieties, having excellent Peaches (Royal George), good Nectarines (Lord Napier), and fair Grapes. Mr. McIndoe was a good second, and Mr. Tullet, gardener to Lord Barnard, third. Mr. Bannerman led again with four varieties, Pines excluded, his collection including a splendid dish of Royal George Peaches. Mr. Leadbetter was second, Mr. McIndoe third, and Mr. Crawford fourth. Mr. Parker was first with a Pine Apple; Mr. Woods, gardener to F. Foljambe, Esq., being second, and Mr. McIndoe third. Grapes were very good on the whole. Mr. J. Johnson won from eight opponents with Black Hamburg, his being as black as Sloes. Mr. McIndoe was second, larger in bunch but smaller in berry. Mr. Wallis, gardener to Sir H. Meysey Thompson, third, and Mr. Allsopp, gardener to Lord Hotham, fourth, Mr. Bannerman being commended. There were eight stands of Whites, Mr. Anderson winning easily with Buckland Sweetwater, splendidly coloured; Mr. G. Anderson, gardener to A. Milnthorpe, Esq., second; Mr. A. F. Pike third, and Mr. McIndoe fourth. Mr. Bannerman won easily with Peaches, having a splendid dish of Royal George. Mr. Divers, gardener to J. T. Hopwood, Esq., was second, Mr. Wallis third, and Mr. McLean fourth. The prizes for Nectarines went to Mr. Divers, Mr. Slade, Mr. Leadbetter and Mr. Parker. Melons were very good indeed. Mr. McIntyre was first with scarlet, green and also white fleshed, other prizes going to Messrs. Riddell, Wenman, Crawford, Le Pelley, Wallis, and Tullet. The best Figs came from Mr. Bannerman, and the best Cherries from Mr. Divers, who had a splendid dish of Monstruse de Mezel. Mr. R. Anderson was the leading exhibitor of Strawberries, Messrs. Wenman and Divers also having good fruit.

Excellent Tomatoes were exhibited by Messrs. Allsopp, McIntyre, Park, and Wenman, who took the prizes in the order of their names. Messrs. Sutton & Sons and Messrs. Webb & Sons offered special prizes for vegetables. In the class for the Reading prizes Mr. McIndoe was first, having excellent Suttons' First Crop Cauliflowers, Magnum Bonum Peas, Triumph Beans, Long Cream Marrow, Al Tomatoes, and Matchless Cucumber. Mr. Crawford was a good second, Mr. Knight third, and Mr. Smallwood fourth. Mr. Crawford secured the first of the Woodsley prizes with an excellent collection, comprising Walcheren Cauliflowers, Stratagem Peas, Sensation Tomatoes, Purple Argenteuil Asparagus, Market Favourite Carrots, and Snowdrop Potatoes. Mr. McIndoe was second. Mr. Laxton's prize for a dish of Gradus Pca was won by Mr. Smallwood.

#### MISCELLANEOUS.

There were numerous miscellaneous exhibits, and for several of the stands medals and certificates were awarded. Messrs. W. & J. Birkenhead had one of their characteristic displays of Ferns, comprising both popular and rare forms. Messrs. J. Backhouse & Co. arranged a miniature rock garden, backed by Conifers. It was tastefully put together, and much admired. They also had a stand of hardy flowers. Messrs. E. D. Shuttleworth contributed a most attractive stand of greenhouse and stove plants, Roses, and hardy cut flowers. Mr. Alex. Lister, Messrs. Paul & Co., Bridge of Weir, and Messrs. Cocker & Co. had beautiful stands of Pansies and Violas. Mr. J. Forbes also had a bright collection. Messrs. R. Smith & Co. contributed a beautiful group of Irises, Delphiniums, Spiraeas, and Clematises. Messrs. W. Cutbush & Son sent a collection of Malmaison Carnations and other plants, together with a brilliant display of hardy flowers. Mr. B. R. Davis was represented by stands of his well-known strain of Tuberous Begonias. Messrs. F. Sander & Co.'s resources were drawn upon for a charming assortment of Orchids and new and rare plants, amongst the latter being Alocasia Watsoniana, Strobilanthes Dyerianus, Dracaena Sanderiana. Messrs. Charlesworth, Shuttleworth, & Co. also had a

brilliant and tastefully arranged group of Orchids. Mr. Colchester had a stand of his Ichthem guano, and Messrs. Hood & Co. of bracket plaques for cut flowers.

### ISLE OF WIGHT ROSE SOCIETY'S SHOW.

JUNE 15TH.

ON Thursday, June 15th, at Newport, Isle of Wight, in the Vicarage grounds, lent by the Rev. Clement Smith, the first meeting of this Society was held, and it proved to be most successful both as regards the exhibits and the attendance. Her Majesty the Queen, who is the Patroness of the Society, has shown a very great and practical interest in the Society's welfare, and promised a gold medal each year for twenty-four distinct Roses grown in the island. The Show was opened with some ceremony by the Mayor of Newport and Sir Warrington Simeon, and a large number of the local gentry were present, the fine band of the 3rd Battalion King's Royal Rifles (late 60th Regiment) much adding to the pleasure of those present.

The exhibits were arranged in two *marquées*. In the All-England classes the principal exhibitors were Mr. Frank Cant of Colchester, Mr. Charles Grahame of Croydon, Mr. R. C. West of Reigate, Captain Ramsay of Fareham, Dr. Seaton of Hants, and Mr. C. S. Cuthell of Dorking, who may be said to have taken the principal prizes in the order named, Mr. Cant taking four firsts and a second, and Mr. Grahame one first and three seconds. Mr. Cant's exhibits were for twenty-four distinct:—Gustave Piganeau, Caroline Kuster, Maréchal Niel, Général Jacqueminot, Marie Baumann, Medea, Devonensis, Marie Van Houtte, Prince Arthur, Boieldieu, Madame de Watteville, Prince Camille de Rohan, Hon. E. Gifford, A. K. Williams, Ulrich Brunner, Niphetos, Dupuy Jamain, Souvenir de S. A. Prince, La France, Marchioness of Dufferin, Comte de Raimbaud, Horace Vernet, Lady M. Fitzwilliam, Madame Gabriel Luizet. Eight treble Teas:—Souvenir d'un Ami, Caroline Kuster, Souvenir de S. A. Prince, Cleopatra, Ernest Metz, Innocente Pirola, C. Mermet, Marie Van Houtte. Twelve Teas:—Cleopatra, Madame A. Etienne, Madame Cusin, Souvenir de Paul Neyron, Madame Bravy, Devonensis, Marie Van Houtte, Madame de Watteville, Etoile de Lyon, Comtesse de Nadaillac, Hon. E. Gifford, C. Mermet. Six Teas:—Hon. E. Gifford; (silver medal) best bloom, Madame G. Luizet.

In the classes only open to the island growers, the Queen's gold medal was taken by Mr. Brook of Ryde, and the silver challenge cup by the Rev. G. Jeans, the local Secretary of the N.R.S., who has had the brunt of the work in arranging this meeting, and whose energetic services were rewarded by the satisfaction expressed by the exhibitors. Any small drawbacks of a first Show will be rectified by greater experience in the future. We heartily congratulate the Committee on their first effort being so successful.

### NATIONAL ROSE SOCIETY.

EXHIBITION OF TEAS AND NOISETTES.—JUNE 20TH.

NOTWITHSTANDING the prolonged drought, there was a fair display of Tea and Noisette Roses at the above Exhibition, held at the Drill Hall, Westminster, although in some cases the blooms lacked stability and size. Still, taken as a whole, these were better than was generally anticipated, and the competition was fairly keen. Appended are the names of the prizewinners and the varieties they staged.

In the class for twenty-four single trusses, not less than twelve varieties or more than three trusses of any one variety, Mr. J. Bradbury, gardener to S. P. Budd, Esq., 8, Gay Street, Bath, was awarded the first prize for a really grand exhibit. The varieties staged were Comtesse de Nadaillac, Maréchal Niel, Souvenir d'Elise, Souvenir d'un Ami, La Boule d'Or, Jean Ducher, Princess of Wales, Etoile de Lyon, Souvenir de Thérèse Levet, Princess Vera, Catherine Mermet, Ethel Brownlow, Marie Van Houtte, Cleopatra, Madame Cusin, and Comtesse Panisse. R. L. Knight, Esq., Bobbing, Sittingbourne, was placed second with a very creditable exhibit; and H. V. Machin, Esq., Gateford Hill, Worksop, third. The competition in this class was keen, six growers competing. For twelve single trusses, not less than nine distinct varieties or more than two blooms of any one kind, the Rev. A. Foster Melliar, Sproughton Rectory, Ipswich, was first, staging Souvenir d'Elise Vardon, Comtesse Panisse, Ernest Metz, La Boule d'Or, Marie Van Houtte, Comtesse de Nadaillac, Souvenir d'un Ami, Madame Angele Jacquier, Souvenir de Thérèse Levet, Anna Ollivier, and Catherine Mermet. E. B. Lindsell, Esq., Bearton, Hitchin, was second, and O. G. Orpen, Esq., West Bergholt, Colchester, third.

C. J. Grahame, Esq., Coombe Road, Croydon, was first in the class for six single trusses, not less than four distinct varieties. This exhibit included Ethel Brownlow (excellent), Innocente Pirola, Comtesse de Nadaillac (good), Francisca Kruger (fine), and Hon. Edith Gifford. Rivers H. Langton, Esq., Raymead, Hendon, was second with a beautiful stand; and Mr. Croft, gardener to W. D. Freshfield, Esq., The Wilderness, Reigate, third. There were seven competitors in this class. The Rev. A. Foster Melliar was placed first in the class for six trusses of any one variety, showing Souvenir d'Elise Vardon in perfect form. Edward Mawley, Esq., Rosebank, Berkhamsted, was second with Innocente Pirola; and Dr. King, Gayton Rectory, Blisworth, third with Caroline Kuster. E. B. Lindsell, Esq., was first in the class for six distinct varieties, three trusses of each, staging Souvenir d'Elise,

Comtesse de Nadaillac, Caroline Kuster, Jean Ducher, Innocente Pirola, and Etoile de Lyon. The Rev. F. R. Burnside was second, and H. V. Machin, Esq., third. In the class for a decorative arrangement of Tea and Noisette Roses, Mrs. O. G. Orpen, West Bergholt, Colchester, was very deservedly awarded the first prize for an admirable arrangement. Miss Agnes A. Bloxam, Eltham Court, Eltham, was second, and Mrs. Edward Mawley, Rosebank, Berkhamsted, third.

Mr. Frank Cant, Colchester, was first in the open class for twenty-four distinct varieties, showing very fine blooms of Ernest Metz, Niphetos, Souvenir d'Elise Vardon, Innocente Pirola, Madame de Watteville, The Bride, Cleopatra, Anna Ollivier, Comtesse de Nadaillac, Madame Cusin, Catherine Mermet, Madame Bravy, Ethel Brownlow, Caroline Kuster, Souvenir d'un Ami, Madame Hoste, Madame A. Etienne, Princess of Wales, Rubens, Marie Van Houtte, Madame Hippolyte Jamain, L. B. Varonne, La Boule d'Or, and Souvenir de S. A. Prince. Mr. B. R. Cant was second, and Messrs. D. Prior & Son third. In the class for twelve distinct varieties, three trusses of each, Mr. Frank Cant was again first with Cleopatra, Madame Hoste, Marie Van Houtte, Comtesse de Nadaillac, Madame de Watteville, Ernest Metz, The Bride, Souvenir d'Elise Vardon, Innocente Pirola, Madame Cusin, Souvenir de S. A. Prince, and Catherine Mermet. Messrs. D. Prior and Son were second, and Mr. Geo. Mount third.

For eighteen bunches of Roses, distinct, three trusses in each bunch, Messrs. G. Paul & Son, Old Nurseries, Cheshunt, were first. This stand included L'Ideale, Belle Lyonnaise, Bouquet d'Or, Jean Ducher, and Madame Cusin amongst others. Mr. Geo. Mount, Rose Nurseries, Canterbury, was second with a very fine exhibit. Messrs. D. Prior and Son were placed first in the class for twelve blooms of Maréchal Niel. O. G. Orpen, Esq., being second; and A. H. Gray, Esq., Beaulieu, Newbridge, near Bath, third. Mr. Frank Cant, Braiswick, Colchester, was first in the class for twelve single blooms, one variety. He staged magnificent examples of Souvenir d'Elise Vardon. Messrs. D. Prior and Son, Colchester, were second with Niphetos in good form, and Mr. B. R. Cant, Colchester, third with Comtesse de Nadaillac.

The best bloom in the Show was in a stand of the Rev. A. Foster Melliar, and was a perfect specimen of Souvenir d'Elise Vardon.

### FRUIT FORCING.

**Figs.**—*Early-forced Planted-out Trees.*—The second-crop fruits on trees started at the new year are now a good size, they being about three weeks earlier than usual, and if judiciously thinned there will be a crop of fine delicious Figs. If the crop is heavy reduce to eight or nine fruits of the small, five or six of the medium-sized, and three or four of the large fruited varieties to each square foot of trellis covered by the trees or exposed to full sunshine, leaving the most forward at the base of the shoots, which will ripen earlier and attain greater perfection than those near the points. These parts should be kept free from fruit, and be allowed to grow up to the light. This is necessary to secure well ripened wood so as to ensure a full first crop the following season, the trees being at rest by the middle of October. If the borders have been allowed to get dry they must be watered repeatedly until the soil is thoroughly moistened. Liquid manure will be required by trees having their roots in borders of limited extent, and more frequently than by trees with a large extent of rooting area; about once a week in the first case, and every fortnight in the other, giving thorough supplies, and always in a tepid state. A light mulching replenished from time to time will encourage surface roots, and a sprinkling of artificial manure on the border and washed in will assist the Figs to swell.

Syringing must be practised twice daily, except in dull wet weather. If red spider gains a footing it must be dislodged by syringing the trees with a soft soap solution, 2 ozs. to a gallon of water, and scale may be removed from the wood by using a brush. Painting the hot-water pipes with sulphur is an effectual remedy for red spider. Artificial heat will not now be necessary unless the weather suddenly becomes cold and wet, then fire heat will be needed to maintain a night temperature of 60° to 65°, and 70° to 75° by day. Ventilate early, especially on clear mornings, and close sufficiently early to run up to 85° or 90°, or even 95° to 100°, providing plenty of atmospheric moisture.

*Succession Fig Houses.*—When the fruit gives the least indications of ripening by changing colour, afford more air, insuring a circulation constantly by keeping the top and bottom ventilators open a little. Reduce the atmospheric moisture gradually, and expose the fruits as much as possible to the full influence of light and air. Lessened supplies of water will be needed at the roots, but they must not be allowed to suffer. If red spider be troublesome a thorough washing may be given the trees after the fruit has been closely picked, and this repeated each time the fruit is gathered will keep the pest under until the crop is cleared, when more effectual means can be employed for its eradication. It must be done early on a fine day, and the water be soft, clear,

and tepid; then the fruit will not be deteriorated, otherwise the fruit may be discoloured and acquire a musty flavour.

**Trees Swelling their Crops.**—A mulching of short manure will act as a source of nourishment, uniform moisture in the border, favouring surface roots, which in an active state can be fed with top-dressings of phosphatic and potassic manures to any extent without unduly exciting growth. A handful per square yard of five parts dissolved bones, two parts powdered saltpetre, and three parts ground gypsum, mixed, will assist Figs to mature heavy crops of fruit and make sturdy, healthy, fruitful wood. Syringe twice a day in fine weather, always early in the afternoon, closing the house at the same time, and so as to gain enough sun heat to rise to 90° or 100. The fruit will then swell to a good size, and rest being insured at night by allowing the temperature to fall to a safe minimum the trees will be capable of performing a long day's work.

**Late Houses.**—Trees against walls covered with glass often grow rampantly, and root-pruning affords little better results as regards fruit, because the trees are too far from the glass. In such it is better to allow them to grow up with one or more stems to the roof and then train the growths to a trellis about 1 foot from the glass and down the slope. The sun then shines into the points of the shoots and they push Figs at nearly every joint. Keep the growths thin, stop at the fifth leaf, that is, side growths, and mulch and water the borders. Ventilate early, and utilise sun heat by early closing, feeding according to the requirements. The trees will ripen one full crop in August, and the second crop Figs being removed and the shoots allowed to grow up to the light so as to get their points well ripened, a full crop may be relied on another year.

**Young Trees in Pots for Early Forcing.**—These must now be in the pots in which they are to fruit and on no account be neglected. Afford all the light possible, and keep the trees well syringed and supplied with liquid manure so as to insure a clean, sturdy, well-nourished growth. When that is complete they should have abundant ventilation so as to ripen it thoroughly. Stopping must not be practised after this date. When the growth is matured the trees may be placed outdoors in a sunny place, but in dull and wet weather means should be at command for warding off heavy rains.

**Vines.**—*Early forced Vines.*—When the Grapes have been cut the Vines must be syringed and, if necessary, apply an insecticide. The syringing should be repeated occasionally so as to preserve the old foliage as long as possible, and encourage a moderate extension of the laterals, especially in the case of weakly Vines and those long subjected to early forcing. Ventilate to the fullest extent day and night, but it is not desirable to remove the roof lights unless they can readily be replaced in case of heavy rains. This is particularly essential where it is intended to lift the Vines and lay the roots in fresh compost, as a wet soil is not favourable to the Vines for lifting.

**Grapes Colouring.**—Those changing colour will require plenty of air, with the needful warmth—70° to 75° by artificial means, affording them rest at night by allowing the temperature to fall to 60°. A thorough supply of water to the border and a mulch of short sweet material, say an inch or two of stable litter freed of the coarser strawy portion, will lessen the need of water. A moderate moist atmosphere must still be afforded by damping occasionally, and it will not do any harm to the Grapes provided air is admitted so as to prevent its deposition on the berries. Muscats must not lack water at the roots, and it will not prejudice the Grapes if air is freely admitted.

**Late Houses.**—Examine the bunches for the last time in thinning, removing any superfluous and stoneless berries, and taking out those in the centres of the clusters, allowing rather more room between the berries than for midseason Grapes. High and dry borders require large quantities of water and liberal top-dressings of artificial manures, with a light mulch to keep the surface uniformly moist, but avoid thick coatings of wet manure. With supplies of nourishment at the roots and damping surfaces at closing time red spider will not appear. Keep the Vines free from gross laterals, not allowing a large quantity of growth to be made, which must afterwards be removed. Leave a little air on at night at the top of the house, and increase it early in the morning, but allow a rise to 80° to 85°, closing so as to run up to 90° or 95°, with abundant atmospheric moisture in the afternoon. Fire heat will only be necessary to maintain a night temperature of 60° to 65°, and 70° to 75° by day, ventilating in dull weather so as to insure a change of air at least once in twenty-four hours.

**Young Vines.**—Syringe copiously early in the afternoon of fine days and close so as to husband the sun's heat, mulching the border to keep the surface moist, affording water or liquid manure when necessary. Stop laterals to one leaf, then the sub-laterals may be allowed to extend on permanent Vines, but on supernumeraries the canes should be stopped when about 9 feet in length, the laterals at the first leaf, and the sub-laterals to one joint as made, keeping them clear of the principal or cane leaves. The latter must be kept clear and allowed to die off naturally, so that the buds at their base may be well formed and nourished.

#### THE KITCHEN GARDEN.

**Tomatoes.**—Already those planted against sunny walls and fences as well as in the open ground have made excellent progress, the first clusters of fruit being set on all that have been kept moist at the roots. Where the flowers that open first fail to set it is evidently due to neglect, the old ball of soil and roots being allowed to become dust dry during the first fortnight after planting. Still keep them uniformly moist at the roots, and if a mulch of short manure or leaf soil is given

this will lessen the need for watering so often. Training the plants should not be deferred till the stems become too stout and brittle to stand being straightened, nor ought any superfluous growth to remain on them to such a time as to need cutting away. Pinch out all side shoots as fast as they form, the exception to this rule being when there is room for one or more leading growths to be laid in a foot apart, enough being saved at the first pinching to meet the case. Plants confined to a single stem or otherwise may be laid in either uprightly or obliquely, according to the head room, and if the fastening back or tying to stakes is done once a week there will be no breaking down of stems or branches.

**Early Potatoes.**—Owing to the excessive heat and long drought early Potatoes are maturing more quickly than is desirable, the crops being light accordingly. This, as far as Ashleafs and other extra early varieties are concerned, is an advantage. After drought has once caused a check to tuber growth, a change to wet weather, or even a moderate amount of rain on a single day, will start them "growing out," the former also being most probably a precursor of disease. In anticipation of this either lift the crops or draw the haulm before the latter is actually ripe. When the haulm falls about the rows constantly the tubers are quite fit for lifting and storing. By standing on the rows the haulm can be drawn without disturbing the crop underneath.

**Saving Potatoes for Seed.**—Short-topped, quick-maturing varieties of Potatoes ought always to be extensively grown in private gardens, and would be far more than they usually are if only enough tubers were available at planting time. The initial mistake is in using the early varieties too closely every season. This summer there will be less need for doing this owing to the second early varieties being also ready for use. Try some of these latter, and if appreciated save the earlier varieties for seed purposes. Supposing these latter have ceased growing lifting may be commenced at once. Sort over the crop, saving all the medium-sized tubers for storing thinly in a cool light shed or room, the rest being used. Avoid any attempt at greening the seed tubers in the open, as this may invite an attack of disease.

**Crops to Succeed Potatoes.**—According as Potatoes are lifted the space between the rows should also be loosened with a fork, all clods being broken, and the surface generally left in a finely divided level state. It will then be easily made ready for any succeeding crop, and moisture also, to a certain extent, prevented being drawn out. Good successional crops to Potatoes on early borders are Strawberries, Carrots for drawing young, late Kidney Beans, Lettuce, and Endive. In the open quarters Strawberries, late Peas, Broccoli, Borecole, Savoy, Coleworts, Leeks, Endive, winter Spinach, and Turnips might all be put out in succession to early and second early Potatoes. For either Strawberries, or any member of the Brassica family, the ground should be well trampled, and if very dry drills may be opened and soaked with water prior to planting. It is useless to sow seeds on dry ground during the summer, but if the drills opened for them are well moistened before they are sown germination will soon take place.

**Cabbages and Coleworts.**—The former present a very poor appearance, especially on unfertile soils, and if planted on the level or not moulded up it is a difficult matter to supply them with the requisite moisture at the roots. Any late planted should have a good soaking of water, after which the soil may well be drawn up to them from each side. In the furrows thus formed between the rows pour water or liquid manure, notably sewage, rather freely, and a rapid growth of Cabbages will be the result. There is every likelihood of green vegetables being scarce next winter owing to the loss of Broccoli, Borecole, and Savoy plants from attacks of the Turnip flea, and a good supply of Coleworts would be very acceptable. Sow seed of the Rosette, Shilling's Queen, Little Pixie, or other preferred varieties, and later on put in the plants thickly wherever room can be found for them.

**Young Carrots.**—There is always a demand for these, and if seed is sown now of any of the stump-rooted varieties as well as what may be left of Intermediates, it will most likely be the means of providing a long supply of tender young roots throughout the autumn and early winter. Grubs are the worst enemy to this crop, and after drills have been opened 9 inches apart on fine light ground and duly watered sow wood ashes thinly with the seed.

**Late Peas.**—A few late dishes are quite as much appreciated as very early ones, and if room can be spared an attempt should be made to grow some. Ne Plus Ultra, Omega, Latest of All, and Veitch's Perfection are among the best for present sowing, the first-named being the favourite late variety. If 6-feet spaces are left between Celery trenches these suit late Peas surprisingly well, and they will also thrive admirably on freely manured deeply dug ground if kept moist at the roots during the first few weeks. Avoid low ground, as it is there where early frosts do the most damage. Open rather deep drills, well soak with water, and cover the seed with not less than 2 inches of soil. Peas that are already sown and up should be kept regularly moist at the roots, or mildew and other evils will quickly put in an appearance. Such crops ought to have thorough soakings every few days, dribblets being simply thrown away; also mulch heavily with strawy manure.

# THE BEE-KEEPER.

## APIARIAN NOTES.

### THE WEATHER AND BEES.

TILL the beginning of the second week of June the drought was doing no injury, but a dry north-east wind since has caused many plants to suffer, preventing the secretion of honey to the extent bee-keepers desire. Nevertheless we cannot complain. Although not yet at the usual supering time by several weeks many are not only on, but are near completion. For the purpose of making clear the working of my hives I have classed them into three sections. The first were early swarmers, which I made no attempt to control. The second, a little later, I allowed to swarm once, preventing after swarms by excising all queen cells on or about the eighth day subsequent to the first swarm, stocks and swarms all working in their supers. The others are what I wish to be non-swarmer. These are very strong, and have one tier of supers well forward. Singular to say, the last-named, with one exception, a crossed Syrian, the best hive in my apiary, which has never been fed since the bees were put into the hive years ago, are Punics, proving that they enter supers freely and do not swarm readily while they have plenty of room.

### PUNICS AND WEIGHT OF HIVES.

A pure Punic has bred to a great extent for the three seasons I have had her, and is still alive, although it was supposed she was a year or more old when I obtained her. The bees swarmed on June 13th, and are working and carrying in honey to a considerable extent, disproving the statement "they gathered no honey." They have not robbed others this season, such as Italians are doing, while they are not so bad-tempered as some other varieties.

The honey gathered this season does not lose in weight as it did last year. With a copious rain, and ten days' mild weather any time during the next month the yield of honey will be great. I have weighed one medium swarm, and its gross weight is 75 lbs., and the nett contents of the hive 35 lbs. About half a mile distant from me, at Sydes Cottage, a few minutes' walk from High Blantyre station, is a swarm of crossed Punics, swarmed and hived on June 1st, which on the evening of the 15th, when weighed, turned the scale at 94 lbs., the nett contents of the hive being 74 lbs. Any person is welcome to visit the place and see for themselves the accuracy of the statement.

### INDUCING BEES INTO SUPERS.

Last week I made allusion to the old method, which I have often referred to, of giving bees supers under the brood nest at first to prevent swarming, and by utilising the combs as supers thus hurrying on that work. Dr. C. C. Miller in "Gleanings" says, "Simmins has made a decided improvement in the non-swarmer plan. Formerly the system was to have the bees always building comb between the brood nest and the entrance; as fast as the bees built the comb, cutting it out and fitting it into sections. Now he puts sections under instead of brood combs, then raises the sections when well started."

Supers following the first ones will be put uppermost, unless where they are small in four or two sections. In these cases half of the partly full supers will be lifted and put on the other half, empty ones taking the place of those that are moved.

### THE HEATHER.

With so much heat and sunshine, and little rain, the Heather has made long growths, is early, and very promising. The preparations for taking the bees to it will be earlier than is usually the case. Take every precaution to prevent smothering, ventilating floors, with an upward current for the escape of the heated air, shallow combs, gentle handling, and with flexible springs on the vehicle the hives in most cases will travel long distances with perfect safety. When a hive shows signs of distress from over-heating sprinkling a little cold water upon it will have a good effect.

I never send bees to the moors with partly filled supers. Do not let bees crowd. If at any time the bees incline to "lie out" give extra space at once. Feeding with advanced hives is a thing of the past; still, if there are any late swarms, and the weather unfavourable, feed a little. Sometimes this applies to hives deprived of their honey.—A. LANARKSHIRE BEE-KEEPER.

## TO CORRESPONDENTS

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Disfigured Peach Leaves (W. M.).**—The box containing the leaves came to hand too late for a thorough examination this week. The matter shall be fully dealt with in our next issue.

**Scabbed Potatoes (Constant Reader).**—A reply to your query was given on page 449 of the *Journal of Horticulture* for June 1st. No flower came to hand with the Potato, otherwise it would have been named.

**Preventing Earwigs Eating Apricots (Apricot).**—The earwigs are best trapped before the fruit commences to ripen. Beanstalks or hollow stems of any kind of plant, if cut into lengths of from 6 to 9 inches, and placed in the branches of the tree, will catch a large number. Small flower pots, partly filled with dry moss, and either inverted or laid on their sides in the forks of the tree, may also be used effectively. In either case the traps must be frequently examined, and the earwigs shaken out into a vessel containing boiling water. By commencing early, and attending well to the traps, the earwigs may be captured, and the crop of fruit saved.

**Names of Insects (J. D. Duffreyn).**—Other food being inaccessible, the larva enclosed in your box assailed its companions, and devoured the greater part of the beetle's body, also some portions of the moth. Owing to this the beetle cannot be identified. It would seem to be a species of weevil, and was doubtless engaged in sucking the juices of the Grapes. The moth is the species called the small elephant (*Chœrocampa porcellus*), because the head of the caterpillar has been thought to resemble the elephant's trunk, or, according to other observers, the snout of a pig. It is rather a sluggish but pretty insect, and not very common. Your larva is the grub of the cockchafer beetle (*Melolontha vulgaris*), which has been noticed in several places this season, as doing much injury to the roots of various plants. It feeds slowly, pursuing its destructive work for some years.

**Todea superba (A. M.).**—It should be grown in a pot well drained, using a compost of three parts fibrous peat, one part yellow loam, and a half part each of sandstone or crocks broken rather small, and silver sand. The peat and sand ought to be torn up moderately small, and the whole must be well mixed; pot moderately firm. Keep the soil constantly moist, and place the plants in a cool shady part of the greenhouse. If the house be small the plants will do without a glass, but if not sufficiently close and moist it should be covered with a glass just resting within the rim of the pot, and if it has no hole in the top it should be taken off and wiped dry once daily. The plants should be gently sprinkled with water once a day in bright weather through a very fine-rosed can. The plants having the requisite moisture, the fronds will be covered with minute dewdrop-like spots of water in the morning if the glass is tilted a little on one side at night.

**Scutellaria macrantha (Amateur).**—This is a native of Eastern Asia, and appears to be widely spread, extending, according to Sir William Hooker, to the great wall of China, where it was detected by Sir George Staunton. It is perfectly hardy and of easy cultivation and increase. It is an herbaceous perennial, scarcely exceeding 1 foot in height, with angular, branching stems, and opposite, entire, lance-shaped leaves, and forming when sufficiently strong a spreading bushy tuft. The very handsome purple flowers are produced in long terminal spikes. The plant seeds freely, and may be readily increased by these means as well as by division of the roots or by cuttings under a glass, either in the border or frame. Seedlings usually flower the first season if sown early, and should be transplanted from the seed pan while young, as they will suffer less from removal than at a more advanced state of their growth, when their tap-like root is more developed.

**Culture of *Pancratium fragrans* (S. R.).**—This beautiful plant requires a rather high temperature and a moist shady position; a stove heat of 70° in summer and 60° in winter should be the minimum. Your plants should be shifted as soon as they fill their pots with roots. When the specimens are as large as required they must only be potted every

four years. Employ a compost of two parts fibry loam, one part charcoal, and one part silver sand and sheep droppings. The loam must be broken into pieces about the size of pigeon's eggs, the charcoal the same; when all has been turned two or three times it should then be run through a half-inch riddle, and what remains in the riddle place in the pots. In potting the soil should be rammed very firmly. In the stove they must be close to the glass, but shaded from the direct rays of the sun, and they should receive a bountiful supply of water in the summer both from the watering can and the syringe. Even during the winter the syringe must be more freely employed than for most stove plants, particularly so if the stove in which they are placed is not furnished with vapour appliances. They can be placed in a cool conservatory when in flower, and supplied with a little weak liquid manure; it prolongs their flowering season, and also imparts a much finer waxy appearance to the flowers—moreover, they last much longer in a cut state when subjected to this treatment.

**Souvenir de la Malmaison Carnations** (*L. T. P.*).—With very light adequately heated low span-roof houses, or pits for the plants in winter and spring, striking stout cuttings periodically, and growing the plants well, blooms may be had more or less plentifully throughout the year, but they cannot be relied on in the absence of adequate means for producing them, such as an ordinary greenhouse crowded with a variety of other plants that require different treatment. The plants may be grown in cool frames, or even in the open air, in the summer, and will then produce flower stems and buds that will expand in a very light house having a genial temperature between 50° and 60°. Established plants will flower from the present time till the autumn, and strong cuttings rooted now will, if well grown, flower in the winter and spring. A supply of blooms cannot be had all the year round, from, say, a dozen plants all in the same stage of development. Carnations are best produced in the winter in houses that are practically devoted to the culture of the plants, and it is in this respect that growers of flowers for market have the advantage over the majority of private gardeners and amateurs, whose glass accommodation is limited, and who have to grow a great variety of plants together in the best way they can. It does not follow, then, that because blooms of the Carnation in question can be had all the year round that it is in the power of all cultivators to produce them.

**Cephalotus follicularis** (*A. D. F.*).—This pretty and interesting little plant is a native of Australia, where it was first discovered by Labillardiere, who described and figured it; subsequently Mr. Robert Brown also found a specimen during his voyage with Captain Flinders. It was first cultivated in England about 1822, and is now by no means a rarity. The plant is remarkable in several ways, for it is the only species of the genus, and is considered sufficiently distinct to constitute a natural order (allied to the Polygonums), and we thus have the peculiarity of a family composed of one individual. In the leaves, too, we find another singular feature—some are flat and elliptical in form, while others are converted into extremely neat and pretty little pitchers or ascidia, somewhat resembling those of *Nepenthes*, only much smaller. They are dark green with a purplish shading, and pink veins, and are furnished with small lids, the mouth of the pitcher being bordered with a dark-coloured furrowed ring. This *Cephalotus* is an inhabitant of marshy land; it should therefore be provided with a soil composed of peat and live sphagnum moss, the pot being well drained and placed in a shallow pan containing water. If the plant is grown in a pan, that should be placed inside another larger one, the space being filled with fine Derbyshire spar and kept constantly moist. In either case a bellglass should be placed over the plant. The best position and temperature is the cool end of the stove or Orchid house, where with careful attention in supplying the requisite moisture the plant will grow freely.

**Fuchsias and Pelargoniums for Autumn** (*Novice*).—All the varieties mentioned in your letter are suitable. Grow the Fuchsias in unheated frames in a shaded position, removing the lights on favourable occasions from now to September, and especially at night for the benefit of the night dew; indeed, the plants will only require protection from sun and heavy rains. Some of the finest we have seen were grown outdoors during July and August, the pots partially plunged in ashes on the north side of a wall. The plants must be kept growing freely, repotting them as may be needed to ensure this, and watering and syringing them regularly. If the wood is allowed to get hard you cannot well retard them. Pinch the shoots as they extend 4 or 5 inches, and permit no flowers to expand till September. The plants must never be root-bound until they are placed in the pots in which they are intended to flower, or the wood will ripen prematurely. When the plants are near flowering clear liquid manure, such as soot water, will be very beneficial. The young plants to which you allude are quite amenable to the treatment indicated, and old plants that flower in July, if pruned slightly, repotted, and grown in the same manner, will flower again in the autumn. Zonal Pelargoniums grown practically in the same way, only in a sunny position, will flower equally well late in the season, young plants producing the finest trusses, old ones affording them the most freely but smaller. Plants that flowered in June, then cut down, and a fortnight afterwards shaken out and repotted, will flower freely in the autumn. Young plants may be topped occasionally till the middle of August, and then have the flower buds picked off if earlier than you wish them. They must not be starved at any time, but

be kept supplied with water as needed to promote healthy growth, giving weak liquid manure occasionally when the pots are crowded with roots and the flowers are forming freely.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*G. E.*).—2, *Sisyrinchium striatum*; the rest were insufficient specimens, being impossible to identify, and were, moreover, badly packed. (*F. D.*).—1, *Saxifraga Camposi*; 2, *S. MacNabiana*. (*L. M.*).—*Adiantum amabile*. (*D. B.*).—*Alocasia metallica*.

### Bedding plants in variety.

**SEED STANDS AT CHESTER.**—At the Royal Agricultural Society's Show at Chester, which closes on Friday night, Messrs. E. Webb & Sons have a very large stand, in which their choicest goods are well displayed, the enormous Swedes, Mangolds, white-fleshed and yellow-fleshed Turnips, prize Wheat and Barley exhibited by the firm attracting large crowds of practical agriculturists. Next to the Wordsley firm came Messrs. Sutton & Sons of Reading, whose specialties of Grasses, roots, cereals, and various agricultural, horticultural, and floricultural produce attracted a constant stream of visitors. Dicksons (Limited), Chester, too, have a grand display, their collection of well-known Grasses, Clovers, Oats, Barley, Wheat, and roots being visited by thousands of visitors, the attendants being kept as busy as bees. Messrs. James Carter & Co. have also a large collection of their various and well-known goods on view.

## TWO FARMS—A CONTRAST.

How much the ordinary farmer of this country is dependent upon seasonable rainfall has probably never been shown so clearly as now, in what is practically the fourth month of a spring and early summer drought. It is true that there has been some rain in certain localities, but no appreciable downfall since February. There has been an abnormally high temperature, and the effect of the combined drought and heat upon farm crops has been alike interesting and instructive. It has taught many useful lessons, and has certainly deepened the conviction that drought at any season of the year tells much more upon crops on poor neglected land than it does upon those having the benefit of rich soil in thorough cultivation.

Since writing our last home farm article we have been over many farms, several of them dairy farms, entirely in grass, and found much of the pasture eaten bare, and the hay crops practically a failure. At none of these farms is there anything done worthy of the name of systematic cultivation; the only manure is from the grazing stock, there is no sheep-folding, no use of chemical manure. This was the case, too, at a farm having the advantage of a few acres of arable land, all sown with corn; pasture and corn were alike in a wretched plight, the corn being also foul with coltsfoot and twitch grass. To tell the tenant how much better he might do whilst he is under the stress of such a time of drought, and straitened in means as he most probably is, would seem absolute mockery. What can be done for him? It is certain that the man who farmed well in good times has been able to hold his own in bad times—to continue fairly prosperous simply because he has continued to farm well. To the inferior farmer the difficulties of the situation become more and more pronounced, and even if he wished to try and do better it would hardly be possible to effect a radical change at once. It is certain, however, that arable land on such a farm should be cropped for stock-feeding, and not to produce corn for sale.

No contrast could be greater than the condition of the crops of another farm, entirely arable, and chiefly devoted to the cultivation of vegetables. There were fields of Cabbages, Onions, Peas, early Potatoes, Lettuces, and Parsnips, all in perfect health and vigour, without a sign of growth arrested or dwarfed by drought. The only crop on the farm which afforded any indication of such an influence was a fine field of Wheat, with short but very stout straw. It was a triumph of cultivation in such a season—not a weed to be seen, the surface well stirred, and the soil evidently full of manure. The importance of the lesson afforded by this vegetable farm cannot easily be over-rated. It plainly indicates how advantageously the principles of gardening may be applied to farming—not in bringing farm land generally under the cultivation of fruit and vegetables, but rather in bringing all soil that is worth cultivation up to a high standard of excellence. In doing this we must go back to the very rudiments of soil tillage, and for example take the case of a dairy farmer who intends trying to improve a certain meadow which is now bare of nutritious herbage, with the surface cracked and seamed with fissures caused by drought. He knows that in ordinary seasons it has always been termed wet, though it is an upland field, and a wise landlord will surely respond to his appeal for drainage in early autumn. With drains in full action sheep-folding may then follow at once; and if

about 4 cwt. per acre of basic slag is applied in the autumn as well, the pasture would be sufficiently stored with fertility to render it really productive next season. Slag at 2s. per cwt. is the cheapest form of phosphate application we have, and if applied in the autumn it does much good in the following spring and summer. With soil so rich in plant food as the meadow would be after such treatment, early growth in spring is assured, however cold or ungenial the weather may be.

For such folding any sheep will answer, but when a choice is possible we prefer either fine sturdy hoggets or really good draught ewes. These may always be had worth the money at autumn markets or fairs. If purchased with judgment they fatten well enough in folds to cover expenses even now. Sometimes they afford a fair profit, but it should be remembered that profit must be looked for in the pasture by its strong vigorous growth next season.

## WORK ON THE HOME FARM.

After sheep shearing comes the dipping, for which purpose we always use Cooper's preparation, only waiting till any wounds from the shearings are healed. Never was the dipping more important than in this hot dry season, flies being rampant everywhere. It is necessary to remind our readers in connection with this important matter, never to dip the ewes while they are suckling lambs; the lambs will imbibe the poison in the dip mixture and die. Wean them, and then dip the lambs too; all should then be safe from fly attacks for some time. Leave nothing to chance, however, but keep a watchful eye upon the flock. A fly-stricken sheep may easily be detected by its restlessness, and a quiet look round enables the farmer or shepherd to tell if all is well without handling the sheep. We have known serious harm done by inattention to the flock during haymaking. Never trust a boy to count or inspect the flock, however great the pressure of work may be; but let them be seen by an experienced man twice daily.

Look closely after cases of footrot in the flock. Trim diseased feet carefully, tenderly, and frequently, dressing the sores with Gell's ointment. By attention and care this troublesome complaint may be kept under, so that there are no extreme cases of feet so tender that the suffering animals kneel while eating. Such "kneelers" in a flock are a disgrace to shepherd or caretaker, and are sure signs of negligence. Any difficult cases should be kept in a paddock or other small enclosure, to admit of frequent examination and extra careful treatment. We have had cases where there was no sore visible and no discharge, yet the foot has been hot and swollen. A linseed-meal poultice is then necessary to relieve the animal and induce a discharge of pus; then a cure speedily follows. The poultice is applied in a bag, with strings to fasten it to the leg. It must be renewed daily, the leg and foot being well fomented with warm water when the poultice is taken off. It is a good plan to examine the feet of all the sheep occasionally, to cut off any hoof growth of undue length, and to remove hard pieces of dirt or stone which may get in the hoof and cause soreness.

## REMARKS.

- 11th.—Overcast all morning; bright sunshine all afternoon.  
 12th.—Overcast all morning; almost cloudless after 1 P.M.  
 13th.—Bright sunshine throughout.  
 14th.—Almost cloudless till 6 P.M.; a little thunder and spots of rain between 7 and 8 P.M.  
 15th.—Bright and hot, with very little cloud till 4 P.M., then cloudy till 7 P.M., but clear again after.  
 16th.—Bright and hot.  
 17th.—Hot, and almost cloudless.

An extremely dry and hot week with no measurable rain, but a few drops fell on the evening of the 14th.—G. J. SYMONS.

VERY few readers of this Journal are in a position to know what an extraordinary amount of glass is devoted to the cultivation of plants, flowers, fruit, and vegetables for the markets. It is not merely round London where so many fresh ventures are being started, but rather in the provinces. At present many of the provincial towns are largely supplied with early vegetables, Cucumbers, Tomatoes, choice fruit generally, and cut flowers by Covent Garden salesmen; but the latter will soon find that not a few of their best customers will be heard from less often than formerly, owing to their being able to procure much that they want locally. That the metropolis will always be better supplied with choice and, more especially, early garden produce goes without saying, for the reason that better prices are nearly always obtained for it in Covent Garden than elsewhere. The more northern growers may have reason to think differently, Liverpool, Manchester, Sheffield, and the Scotch towns—notably Edinburgh and Glasgow—all being good markets for the best of everything.

As I pointed out in a previous communication the days for fanciful prices are over, and each market grower that starts in the neighbourhood of a country town or in easy distance of several, will do well to study the wants of these rather than look much farther beyond. He can at the same time keep in touch with a Covent Garden salesman, and if at any time he has anything good to dispose of that is really needed in London let him send it quickly, or before the high prices ruling suddenly drop to figures not any better or so good as might be obtained locally without the assistance of a middleman other than a fruiterer or grocer. These remarks apply to Tomatoes in particular, as well as early fine and highly coloured Peaches and Nectarines, early Melons during such a season as we are now passing through, Muscat Grapes, and the very best Apples and Pears. Cut flowers sometimes sell well in Covent Garden; but it is not to that quarter that I advise their being largely sent other than at special times. There is nothing disheartening about the fact of London being very well supplied with much that is required of a perishable nature, and I hold that it is greatly to the advantage of the provincial towns and even villages, for many of the latter are becoming good customers to market growers, that such should be the case. The requirements of those are now studied, and this is leading to such a consumption of fruit and choice vegetables, and demand for pot plants and cut flowers, that is most encouraging. This only needs to be properly fostered to be further increased to the advantage of all concerned.

Cucumbers and Tomatoes are undoubtedly among if not the most profitable things to cultivate extensively, but ought not to be solely relied upon to make a venture remunerative. That they can be made to give good and early returns, the latter more than meeting current expenses, there is no disputing; indeed, it is possible to very profitably devote a number of houses solely to their cultivation, but all the same I think that this partakes somewhat of the character of putting all the eggs in one basket, and displays a want of resource that does not augur well for future success. The houses ought, therefore, to be so constructed as to admit of their being turned to account for the growth of either Grapes, Peaches, Nectarines, Cucumbers, Tomatoes, a variety of vegetables and pot plants. None of the houses need be large and expensive

as far as width and height are concerned, the length being optional, or anything say from 50 feet to 200 feet in length. Span-roofed houses are the most popular, and for obvious reason. If it is intended to devote one or more to Grape culture then these may well be about 24 feet wide, 12 feet high at the ridge, and  $5\frac{1}{2}$  feet high at the sides or fronts, hinged lights for the latter  $2\frac{1}{2}$  feet in depth, and the rest wall or boards being preferable to no glass at all at the sides, and only wooden shutters for ventilators. Such houses can have Tomatoes planted all over the floors during the first season, all being trained up to the roof with the aid of strings or stakes, the Vines being planted close to front. The following season the latter must be studied, Tomatoes occupying not more than two-thirds of the border, while during the third year two rows near or trained over the central path would most probably be as many of ought to be grown. In this manner Tomatoes can be made to nearly or quite pay for the cost of constructing and heating the vinery, there being no waiting for two or three seasons before anything can be made out of the speculation. In the autumn, the Tomatoes being cleared out and the Vines resting, the house can be filled with Chrysanthemums, these latter being either kept in pots (the best if most expensive plan) or prepared in the open ground and transplanted to the border. Early Potatoes and Radishes can also be had easily enough from these inside borders without greatly delaying the planting of Tomatoes and Vines.

Prices obtained for early black Grapes are scarcely remunerative, but those who wish to keep the local trade as much as possible in their own hands ought certainly to force a few black Grapes, while if they can colour Muscats fairly well by May or June they will have no difficulty in selling these to the leading fruiterers and salesmen in London and other towns at good prices. Showy late black Grapes, such as Gros Maroc, Gros Colman, and Alicantes, pay very well after October at 2s. per pound, and fine Muscats will always sell better than any other class of Grapes. Even the latter must not be cut and sent to the markets recklessly, the better plan being to let the principal salesmen know they can have superior Muscats whenever they are wanted, special orders always, as they should do, meaning the best prices. Private gardeners who send their surplus produce to market should adopt similar tactics with superior Grapes that will keep, while as regards soft or quickly perishable fruit generally, they must despatch these as soon as fit and take their chance with the rest.

Cheap and serviceable houses, or such as could first be cropped with Potatoes, salading, and Kidney Beans, and then with Tomatoes, are those about 14 feet wide, 9 feet high in the centre, and 3 feet high at the sides, the latter being boarded. If these are constructed on the ridge and furrow system in blocks of three houses two sides will be saved, but it is doubtful economy having a clear current of air right through the whole block, as there may be times when it will be desirable to keep some of the houses hotter than the others. Nor is it wise to dispense with hot-water pipes. Heating is a serious item of expenditure, but it is false economy trying to do without it even for a single season, Tomatoes growing very slowly, failing to set good crops, and are most liable to disease in unheated houses. Such structures would hold at least five rows of Tomatoes, two rows being trained up the roof and the rest either obliquely to the centre or uprightly. With a flow and return pipe on each side of the house, or, if preferred, a flow and a return down each side of a central path, and sufficient boiler power, these houses would grow winter Tomatoes well. These latter, whether grown singly in 10-inch pots or planted out, should pay well. If strong plants are ready for their fruiting quarters by the first or second week in August fairly heavy crops might be set in time to ripen in November and December, and more fruit could be set in January or early in February, this ripening in time to realise 2s. per lb. in Covent Garden.

It is not large consignments of Tomatoes that are wanted

during the winter and spring, and for this and other reasons, which were conveyed or hinted at when these remarks commenced, some of the so-called Tomato houses ought to be devoted to plant and cut-flower culture during the late autumn and winter months, if not still longer. Chrysanthemums are somewhat overdone, but that they still pay fairly well is evident from the fact that some growers annually house them by tens of thousands. What I find pay best are the Madame Desgrange family, taking care to house these before early frost injure the delicate buds; and any white and yellow varieties that are at their best late in December and during January. There is only a very limited demand for Chrysanthemums of any shade of colour during the height of the season, even specimen blooms failing to sell well last year. Those who can grow neat plants of any variety in 8-inch pots would find they sell readily enough at 9s. per dozen wholesale, and 1s. or rather more each retail, paying therefore better than cut flowers.—MARKET GROWER.

(To be continued.)

## FLOWERS AND MUSIC AT EARL'S COURT.

THE management of the Horticultural Exhibition at Earl's Court are to be congratulated on the change which they have made in the disposition of the flower tent. Last year the shows were held in the building at the extreme corner of the grounds behind the band stand allotted to the Grenadier Guards. This plan, however, did not work satisfactorily, as the counter attraction of the music seemed to intercept the public while seeking the flower show in such a secluded situation. The new flower tent is stationed midway between the two chief band stands, and fairly in view of the constant stream of visitors passing between these centres of attraction. The flower show is consequently a much greater point of interest than was the case last year. It might be suggested, however, that the music and the flowers are still more divorced than is consistent with the title of the Exhibition, and that certain other arrangements might have been sacrificed for the purpose of bringing the two into actual contact. The more they are approximated the less are they set into competition against each other. At present the flower shows indicate a tendency to suffer by the estrangement, though they are more patronised than last season. How much better and more instructive it would be if those persons who are idly promenading around the bands could listen to the music and contemplate the floral exhibition at one and the same time. The tent is a lofty and handsome one of some 120 feet in length, and lighted from above by two brilliant incandescent globes. The floor is of strongly consolidated gravel, almost as hard as concrete and most agreeable to walk upon. In an even more favourable situation and with constant inducements to exhibitors, it might become, as it ought to be, the chief feature of the Exhibition.

During the Show of last week the central stages were devoted to the exhibits of Messrs. Barr & Sons, while the whole of the outer sides of the tent were occupied with those of Mr. H. B. May. Both displays very naturally showed the effects of the great heat, and besides necessitating constant attention, were only to be seen in their perfection during the early days of the week. Prominent among the exhibits of Messrs. Barr were Irids, Lilioms, Alstroemerias, Iceland Poppies, with several varieties of *Oenothera*, and other herbaceous plants. The collection of Ferns of Mr. H. B. May, which occupied the whole of a side of the tent, was, however, the chief feature. These were most tastefully arranged, among them being a very fine specimen of *Agliomorpha Meyeriana*, and a handsome plant of *Cibotium regale*. *Nephrolepis exaltata* was also very distinguished, and here and there the curiously whorled *Platynerium*. The whole presented a most refreshing sight in the hot weather, if one disregarded the risk run by so exposing the plants.

On the other three sides stood a great variety of artistically arranged exhibits, also from the establishment of Mr. May, in which *Kentias*, *Crotons*, *Aralias*, *Cocos*, *Dracenas*, *Alocasias*, *Araucaria excelsa*, and other foliage plants formed a background, lightened by the judicious interspersions of flowering plants, such as *Lilies*, *Carnations*, *Anthuriums*, *Begonias*, and *Hydrangeas*, the whole being lightened with a liberal interposition of *Adiantums* and *Mosses*. Such standing exhibitions as this are highly to be commended, and it is to be hoped that the authorities at Earl's Court will see their way clear to repeating them frequently during the season, and so render their enterprise a true resort for the lover of plants and flowers.

## CANKER IN FRUIT TREES.

I DO not profess to know anything about the science of canker in fruit trees; but as to its being a contagious disease I think that theory is a myth. I am of the opinion that it is all a question, as "A. D." points out (page 498), of soil. I know that some varieties will not grow in certain soils, no matter what is done to them in the way of replanting. The soil appears to be deficient in some element or it has too much of another to enable the trees to mature the young growth annually.

It is the shoots of the previous year's growth that suffer during the winter and fail to grow the following spring. I have proved many times that the soil has much to do with it. I have a standard tree of Ribston Pippin that was planted fifteen years since; the stem is thicker than it was then, but the head is no larger than at planting time. It has grown and died back, repeating the process for years in spite of the number of times it has been replanted. It is strange how a certain variety will fail in one garden and be a success in another. I have noticed endless instances of this. Pott's Seedling is the latest case of canker that I have experienced. This variety does not appear to succeed with me, even when planted carefully in fresh ground. I know another garden where this is the best Apple they have for surety in crops; the tree is an aged standard. I also know that it is possible to make some sorts canker in one garden and by replanting it in soil quite different in character to renovate the same trees. If this can be done in the same garden, how can canker be other than owing to the unsuitable character of the soil for that particular variety? I have known persons attempt to cure the disease, as it was termed by them, with the aid of lime and petroleum, scraping the wounds and lifting the trees and manipulating the roots. Instead of killing the canker the tree was killed.

In the case of Pear trees, if we plant Marie Louise, Jargonelle, or Louise Bonne de Jersey in the open the wood cankers as fast as it is made, but if the same sorts are planted against a wall they bear fair crops of fruit and do not show the slightest sign of canker. This fact proves to me that the assistance of the wall enables the wood to mature and thus bear the effect of the frost better. Trees of the two first named were allowed to remain in the open, first as pyramids and afterwards as loose bushes for ten years, but not a single fruit was ever gathered from those trees, although a quantity of blossom was upon them every year. Surely this is a distinct case of maturation of the wood and not anything approaching to a contagious disease.—E. M.

[We have received several other communications on this subject, including an exhaustive article from Mr. Abbey, for which space cannot be found this week.]

## NIGHT-BLOOMING CEREUS.

I HAVE been very much interested with the notes on the Night-blooming Cereus. I have a photograph showing a plant with twenty-five blooms, not very distinct, and I have seen thirty-five and thirty-seven flowers fully expanded. Unfortunately the plant was broken at the stem during some alterations. I kept it for eighteen months without any roots by syringing and damp moss.—WM. SCALES.

I WAS pleased to see the references regarding the Night-blooming Cereus in the *Journal of Horticulture*, and I think I can fairly accurately fix the varieties we had formerly. They were three—*Cereus grandiflorus*, and I believe *C. nycticalus* and *C. Maedonaldiae*. The first named I am quite sure about, and it was a glorious flower in every way. The petals were pure white, standing very erect; the sepals, which were brown outside and bright yellow inside, thrown back almost at right angles from them, the effect of the snowy white petals, backed and surrounded by the halo of yellow, being exceedingly striking. Added to all this, the flower had a most powerful perfume of vanilla, which scented the whole house, and combined with the other qualities already mentioned to make it, I think I may say without any hesitation, the most attractive flower in the whole of my father's collection.

I am practically certain that the second plant I have mentioned was *C. nycticalus*, as what I remember of it tallies exactly with the description and illustration of that variety given in the first volume of the "Dictionary of Gardening," page 298. It was a larger flower than *grandiflorus*, but not so striking when compared with the latter, as the sepals were of a much paler yellow, the contrast with the petals, therefore, not being so great, and it entirely lacked the delicious perfume, but seen alone it seemed perfect, the great size being very impressive.

The third species I do not remember to have seen in flower, as I believe it was a plant of this one that was lost a number of years ago through frost getting into the house owing to something going wrong with the hot-water pipes one night, a loss which was a constant source of regret to my father, as it was getting a fine plant, and he had only one or two small cuttings left. I see from the Dictionary already referred to the description is as follows:—"Sepals bright red and orange, radiating and very numerous, petals delicate white."

The habits of the two first-named plants were much the same, as far as I know. Sometimes in dull weather it appeared uncertain for two or three mornings whether the flower would open the same night; but if, on the other hand, it was bright and sunny, although in the morning it seemed quite unlikely, yet in the evening it would expand contrary to expectation. From this it may be judged how rapid the final expansion was, as an artist friend found to his dismay when he started to sketch it early in the evening, as before he was able to outline the whole the appearance had entirely changed. As far as I remember

the buds would not be at all open till between 6 and 7 P.M., and about eleven or twelve o'clock (rather later perhaps than earlier) they would be fully expanded. Certainly as late as seven the next morning I have seen them not quite closed, but soon after that they would be hanging down, looking most disconsolate.

I am sorry I cannot give you any fuller or more reliable information, as I should much like to, seeing they were such favourite plants of my father's. I may add that we seldom had more than one, and I think never more than two out on the same plants at one time, and I should say a dozen during the season would be quite an outside number.

I enclose two photographs, the particulars pencilled on the back, but am uncertain of the facts as regards the one I believe to be *grandiflorus*. My sisters tell me that when in North Wales some five or six years ago, they went over a gentleman's garden with my father, which was quite a show place near Penmaenmawr, and there they saw a large *Cereus* which had from twenty to thirty buds on it; but alas! as to variety they cannot speak. All they know is it was a night-bloomer.—MARK B. F. MAJOR, *Cromwell House, Croydon*.

[The photographs depicted the blooms well, but were scarcely suitable for reproduction.]

### GLASS COPINGS AND PEACH FAILURES.

WHILE not wishing to say one word against glass copings for walls, I think very good crops of most kinds of fruit can be obtained without them in the south of England. I am acquainted with a garden where Cherries fail on the walls, owing it is said to the presence of fixed glass coping keeping rain from the leaves. Our trees on a west wall seldom fail to bear abundantly, and they are neither protected with glass copings or anything else. Peaches and Nectarines I regard as the most certain outdoor fruit. Speaking generally, the principal cause of failure to obtain full crops of Peaches annually is owing to a want of maturity of the growth. Whether the trees are under the protection of glass copings, or in the open against the wall, the result is the same. All the useless growth should be cut out directly the fruit is gathered, also keep the trees sufficiently thin all the summer. Why the pruning is deferred until the spring I never can understand.

In some cases the cause of failure is in feeding the trees too liberally with stimulants. Peach trees require but little of this, except where the fruit crop is a heavy one and the growth weak. Where the roots are low in the border, too far from the warming influence of the sun upon the surface, the wood cannot mature in such a manner as to give satisfactory results. Peach trees prefer a firm surface soil; even if it were not interfered with for ten years by digging amongst the roots, it would be all the better if the roots were in the position they ought to be—close to the surface. Where vegetables are cultivated over the roots of the trees the crop of Peaches will be thin, adding manure to the soil and disturbing the roots being conducive to gross growth, which Peach cultivators do not like to see.

Another cause of failure is in some instances, especially where the soil is light, due to want of sufficient moisture at the roots all through the summer and autumn. When a crop of fruit is gathered the careless cultivator is apt to forget the trees for some months in the matter of supplying the roots with water. The fruit is gone and the trees have completed their season's growth, and what more beside maturity can the trees require? This latter, it is often thought, needs assistance, though, to acquire the right kind of matured growth. In light soil during hot weather it is much easier to give trees too little water than too much in the autumn.—HANTS.

CYPRIPEDIUM × CHARLES RICHMAN.

THE illustration (fig. 92) represents a bloom of this fine hybrid *Cypripedium*, which is the result of a cross between *C. bellatulum* and *C. barbatum*. A plant of it was shown at the Drill Hall on May 9th by Mr. C. Richman, Springfield, Trowbridge, when an award of merit was adjudged for it by the Orchid Committee of the Royal Horticultural Society. The dorsal sepal is whitish, veined with deep rosy purplish shade. The petals are broad, similarly coloured, and covered with minute dark spots. The lip is a dark purplish brown.

### ORCHIS MACULATA SUPERBA.

ON a recent visit to the gardens at Kirkconnell House, Dumfries, N.B., the residence of Mrs. Maxwell-Witham, I saw a fine clump of this plant, which is rarely seen in good condition in gardens. I sent a spike to the Editor, who will, I think, agree that it was really beautiful, and, considering the season and the character of the soil, of exceptional merit. The ordinary *O. maculata* is very pretty, but this form is superior, the spike being much longer, the flowers more numerous and densely packed together, while they are also of a fine purple colour.

This large variety appears to be difficult of cultivation, and Mr. John Harper, the gardener at Kirkconnell, has courteously favoured me with some particulars regarding it. The original plant from which that under notice was taken was found near Rowallan Castle in Ayrshire, and has been under cultivation for eighteen years. That at Kirkconnell was brought by Mr. Harper on entering on his present appointment about four years ago. This variety of *O. maculata* appears to have been frequently found on Kenwick Moor in Ayrshire, and has occasionally been named

FIG. 92.—CYPRIPEDIUM × CHARLES RICHMAN.

*O. Kenwicki*, another name being *O. maculata* "Kilmarnock variety," it having been put into trade by a Kilmarnock firm. Mr. Harper has grown it in stiff clay, with the flowering part of the spike no less than 13 inches in length; but the plant at Kirkconnell is at present in a dryish border of alluvial soil, impoverished by the addition of ashes in order to make it more suitable for some rather tender plants for which it was originally intended. The spikes were thus shorter than the length mentioned above, but they were of sufficient size to form an object of great beauty.

*O. maculata superba* has been found to be short-lived in some gardens; but Mr. Harper's experience would show that in cultivation it may attain a long life. In my garden I have had for over three years a variety of *O. maculata* under the same name, but not so fine as that at Kirkconnell, and this appears to require occasional removal to fresh soil and copious supplies of water while making growth. This year it is much inferior. *O. maculata* varies much in a wild state, and Mons. H. Correvon, in his new work, "*Les Orchidées Rustiques*" (Geneva, 1893), names the following varieties:—*Recurva*, *Bonanniana*, *longibracteata*, *macedonica*, *macrostachys*, *Meyeri*, *sudetica*, and *lusitanica*. *O. lapponica* is said to be a northern form of *O. maculata*.—S. ARNOTT.

[The spike received from our correspondent was very fine indeed. The flowered portion measured 7 inches in length, and was 5½ inches in circumference.]

### ROYAL HORTICULTURAL SOCIETY.

JUNE 20TH.

SCIENTIFIC COMMITTEE.—Present: Dr. M. T. Masters (in the chair), Mr. Morris, Mr. McLachlan, Dr. Müller, Prof. Oliver, Dr. Bonavia, and Rev. G. Henslow, Hon. Secretary.

*Scale on "Retama."*—Mr. Morris observed with reference to this subject brought before the last meeting, that the name of the *Retama* is *Cytisus nubigenus*. It is the only ligneous plant growing on a platform at an elevation of 8000 feet on the Peak of Teneriffe. The whole of the plants were covered with the scale. Dr. Perez had noticed no instance of this scale insect appearing until Australian trees had been introduced into Teneriffe. Mr. Morris added that it has now appeared at Kew on the English Broom.

*Honeydew on Limes.*—Mr. Morris remarked that this had been so abundant on the Limes at Kew that the cement pavement below them had become quite slippery from the drip from the trees. Mr. Henslow added that he remembered a similar occurrence from an Ash tree in a garden in Regent's Park Road about the year 1878.

*Oranges in Devon.*—Mr. Morris exhibited photographs of Orange trees growing and fruiting successfully in arched recesses at Coombe Royal,

near Kingsbridge, Devon. They were protected in front during the winter.

*Cochineal in Teneriffe*.—Mr. McLachlan raised the question of the cultivation of this insect in Teneriffe, as the industry appears to have decayed in consequence of the introduction of aniline dyes. Mr. Morris observed that it was somewhat reviving, as there was a certain demand for colouring fruit, preserves, &c. Dr. Müller added that it would be always required as a source of carmine, as this colour cannot be replaced by any other known product.

*Thereva nobilitata in Celery*.—Dr. Müller exhibited grubs resembling wireworms, which were found in decayed Celery plants. They proved to be those of a brown fly. This usually lives in rotten wood, but whether the grubs destroyed the Celery or were feeding on the decayed roots, &c., was not clear. It was suggested that possibly they were carnivorous, as other grubs had disappeared from the soil.

*Calochortus and Lily, Monstrous*.—Dr. Bonavia exhibited flowers, each consisting of two flowers united on one floral receptacle. An examination of the fibro-vascular cords showed that these had arisen by chorisis from a normal stem. *A propos* of this, Mr. Henslow said that he had examined the cords in a germinating Cockscomb, and found that the multiplication of the bracts and flower buds arose in a similar way. The zone of cords being circular in section below, the cords rapidly increased in number by bifurcation above, one branch entering each bract and a small cluster each flower bud. Hence fasciation would be better described as the effect of cauline chorisis, and not as a fusion of a number of independent buds, as the term seems to imply.

*Azolla pinnata Fruiting*.—Mr. Greenwood Pim sent specimens in fruit. He writes—"The plants had been growing in the open air for two years in Co. Wicklow, and had increased to a large extent. Two or three months ago a quantity was placed in a shallow peaty pool, which is now almost dry, having only a few inches of water. In this the plant is producing fruit on almost every fully developed individual."

*Linaria repens* × *vulgaris*.—Mr. Henslow showed specimens of this hybrid which has occurred spontaneously near the station at Oxford, with the following remarks received:—"L. repens was not known prior to 1889, when ballast was brought from Didcot. It appeared in 1890 side by side with L. vulgaris. In 1892 a complete chain of hybrids was found from L. repens, with a little yellow on the lip, to L. vulgaris, with the faintest striæ on the flower."

#### EXAMINATIONS IN HORTICULTURE, 1893.

THE following class list of the Royal Horticultural Society's examination in horticulture has been sent us for publication. There were seventy-six candidates in the higher grade, and 128 in the lower grade:—

##### HIGHER GRADE, SEVENTY-SIX CANDIDATES.

FIRST CLASS (OVER 200 MARKS).—F. V. Dutton, 235; W. Busby, 205; John Lewis, 205; H. Nickolls, 200; A. E. Smith, 200; J. D. S. Dowse, 200.

SECOND CLASS (BETWEEN 200 AND 150 MARKS).—E. G. Gilmore, 190; A. J. Manning, 185; Geo. Witts, 180; S. Morrill, 175; H. Ames, 175; A. N. Pierce, 170; J. T. Emmott, 170; G. Butcher, 170; G. A. Bishop, 170; Winifred Blake, 165; W. J. Stokes, 165; William West, 165; C. J. Dicken, 165; Jno. Barrett, 160; M. Byrne, 160; H. Fincham, 160; J. H. Rewcastle, 150; S. C. Meire, 150; E. Caesar, 150; E. Farris, 150.

THIRD CLASS (BETWEEN 150 AND 100 MARKS).—G. F. Finley, 145; C. F. F. Hutchings, 145; F. Gudgin, 145; A. Ashdown, 145; J. Tufna'l, 140; R. J. Tabor, 140; J. H. Morton, 140; A. J. Bridges, 140; J. H. Parkin, 135; R. C. Gant, 135; W. T. Wagstaff, 130; F. W. Humphreys, 130; J. Morrison, 130; D. Somerville, 125; A. G. Rule, 125; A. C. Bailey, 125; T. A. Young, 120; Geo. Beech, 120; E. J. Eggleton, 120; S. E. Yetman, 115; W. Pascoe, 115; W. F. Gullick, 115; E. Waller, 115; H. F. Tagg, 110; W. N. Sands, 110; Hy. Overy, 110; Lilian E. Clarke, 110; Alfred Catt, 110; W. Chamberlain, 110; Ar. E. Philbrick, 105; W. Milne, 105; E. J. Elliott, 105; A. G. Dangerfield, 105; J. Carter, 105; G. R. Saunders, 100; W. Douglas, 100.

##### LOWER GRADE, 128 CANDIDATES.

FIRST CLASS (OVER 200 MARKS).—H. S. Dainc, 240; W. R. Goff, 225; J. J. Miles, 225; George Lamb, 220; W. Stroud, 205; G. R. Waterson, 200.

SECOND CLASS (BETWEEN 200 AND 150 MARKS).—W. E. Watkins, 195; E. J. Woodard, 190; A. H. Dudley, 190; C. Pine, 190; G. J. Berry, 185; Edward Chopping, 180; M. T. O'Connell, 175; George Wall, 170; Alfred D. Morris, 155; D. Clague, 155; F. G. Drew, 155; C. Barnett, 155; A. D. Hogg, 155; C. W. Avins, 155; J. R. Ismay, 150; H. P. Bridges, 150.

THIRD CLASS (BETWEEN 150 AND 100 MARKS).—C. Weston, 145; A. Melville, 140; W. S. Walker, 140; Frances E. Oldham, 135; F. A. Littlejohn, 135; G. A. Murrell, 135; A. C. Bartlett, 135; T. F. Badcock, 130; J. Newman, 130; Jas. Simpson, 130; P. J. Gray, 125; Frances Mil. Cooper, 125; J. Blonfield, 120; Jas. Davis, 120; W. Farr, 120; G. Beale, 120; Gert. Gaskell, 120; G. M. Stuart, 120; Frank Allen, 115; Annie G. Stephens, 115; J. H. Aitken, 115; J. A. Matthews, 115; W. McCreath, 115; F. N. Woodward, 115; J. F. Dancer, 110; Edmund Fry, 110; T. Gardner, 110; Hy. Bates, 105; W. E. Loe, 105; A. Crossley, 105; A. Blake, 105; W. Burgess, 105; W. Bygraves, 100; W. J. Woolley, 100; Arthur Osborn, 100; G. Hinton, 100; Gilbert Hart, 100; G. T. Bridges, 100.—MAXWELL T. MASTERS, JAMES DOUGLAS, *Examiners*; W. WILKS, *Sec. R.H.S.*

OUR INDEX.—We publish this week an index to the matter that has appeared in the *Journal of Horticulture* during the past six months. Owing to this and the extreme pressure on our space consequent on the reports of Rose shows, we are compelled to withhold many interesting articles and letters till our next issue. We thank our correspondents, and assure them that prompt publication or otherwise in no sense indicates the appreciation of their communications.

— EVENTS OF THE WEEK.—Rose shows are now the order of the day. As notified in the list published elsewhere, Eltham, Sittingbourne, and Windsor Shows are held to-day (Thursday), and on Saturday, July 1st, the Metropolitan Exhibition of the National Rose Society will take place at the Crystal Palace. On Tuesday, July 4th, shows will be held at Bagshot, Diss, and Gloucester, and on Wednesday, July 5th, at Croydon, Ealing, Farnham, Hereford, and Lee, the latter continuing the following day. A Floral Fête will be held from 8 P.M. to 12 P.M. in the Gardens of the Royal Botanic Society, Regent's Park, on the 5th inst. On July 6th exhibitions are to take place at Bath, Farnham, Manchester, and Norwich.

— THE WEATHER IN LONDON.—After a prolonged period of drought rain has fallen to an appreciative extent. Occasional showers occurred on Saturday, rain falling heavily during the night. Sunday was fine, but Monday opened showery, though it cleared before the day was far advanced. Tuesday was dull with rain in the afternoon, and on Wednesday morning it was showery.

— WEATHER IN THE NORTH.—Since the afternoon of Thursday last several heavy showers of rain have fallen, and the temperature has been considerably lower. In some districts more rain has fallen than in this. Monday was fine, especially in the afternoon and evening. During the night a great deal of rain fell, and this morning (27th) is very wet, with every appearance of a rainy day.—B. D., *S. Perthshire*.

— LECTURES ON ARBORICULTURE.—A series of lectures on arboriculture was commenced by Professor Curtis at the Garden and Forestry Exhibition, Earl's Court, on the 17th inst. The lecturer in the course of other remarks, referred to a specimen of the Douglas Fir (*Abies Douglasi*) from Lord Carnarvon's Highclere estate in Hants, and dwelt on the large amount of timber produced by that tree in a given time, much greater than by any other. Regarding the origin of the Larch disease, which he showed on a Larch exhibited, Professor Curtis considered that the disease is due to the fungus (*Peziza Wilcomi*) penetrating the Larch wherever it is injured, either by the fall of a branch or by the teeth of rodents, and it causes an exudation of turpentine and an injury to the wood substance, ultimately destroying the tree.

— WASPS' NESTS.—Mr. E. Molyneux, Swanmore Park, writes:—"The long-continued spell of hot and dry weather is multiplying the wasps. On Friday last within a quarter of a mile of the garden thirty were destroyed. By employing cyanide of potassium little trouble need be encountered in the taking of the nests as compared to the use of the old-fashioned squib made of gunpowder and sulphur. By dropping half a teaspoonful of cyanide into the mouth of the entrance hole at any time during the day nothing more is needed. The incoming wasps quickly feel its effects, while those already in the nest cannot get out, the fumes of the potassium at once suffocate them. Seventy wasps' nests have been taken within 600 yards of this garden."

— FINE ANTIRRHINUMS.—I send you a few Antirrhinum spikes for your opinion. I grow a large number of them, and for a grand display at this time of the year I think they cannot be excelled. There are many colours, selfs and stripes, but I prefer the latter. The spikes sent are from cuttings inserted last autumn. I also grow many seedlings and select the best. The seedlings generally have the largest spikes, and they flower after the others are over. They have been better in previous years, but that is accounted for by the very dry weather that we have had, and they have not had any attention in the way of watering since they were planted. These Antirrhinums are so easily grown, and the wonder is that they are not oftener seen.—JOHN HARPER, *Kirkconnell, Dumfries*. [The spikes were very fine, nearly 18 inches in length, and carrying upwards of fifty expanded flowers.]

— **THE EASINGWOLD EXHIBITION.**—The Easingwold Floral, Horticultural, and Industrial Society's Exhibition will be held on August 30th, and not on August 23rd, as was at first advertised.

— **MONS. ERNEST BERGMANN.**—We are informed that Mons. Ernest Bergmann, the Secretary of the National Horticultural Society of France, has received from His Majesty the King of Portugal the Knight's Cross of the Order of Christ.

— **THE WORSHIPFUL COMPANY OF GARDENERS,** of which the Rev. W. Wilks, M.A., the popular Secretary of the Royal Horticultural Society, is Master, will hold a dinner at 6.30 P.M., at the Whitehall Rooms, Hotel Métropole, on July 12th, 1893.

— **EXHIBITION AT LYONS.**—It is reported that on Sept. 14th and four following days the Association Horticole Lyonnaise proposes to hold on the Cours du Midi, Perrache, an Exhibition of horticulture, viticulture, and objects of art and industry connected with them.

— **THE LIVERPOOL HORTICULTURAL ASSOCIATION.**—We are informed that the fourteenth summer Flower Show of this Association will be held on the Review Ground, Sefton Park, Liverpool, on July 26th and 27th. The Chrysanthemum and Fruit Exhibition will take place on November 15th and 16th.

— **NEWCASTLE SUMMER SHOW.**—The Newcastle Summer Flower Show will be held on July 20th, 21st, and 22nd, in conjunction with the great Exhibition of the Northumberland Agricultural Society. The Society is at present in a flourishing condition, and with the other attractions we have no doubt the Show will be a success. Particulars are given in our advertisement columns.

— **WEATHER AT LIVERPOOL.**—After weeks of drought and intense heat, which seriously affected vegetables, flowers, and fruit, and left lawns in a brown state, the weather reached the climax on Saturday and Sunday, the 17th and 18th, when the thermometer stood on those days over 90° in the shade. Monday, Tuesday, and Wednesday there was a perceptible cooling down in the atmosphere, denoting that rain could not long be delayed. About 4.30 P.M. on Thursday the long-looked for rain descended in copious showers, and they continued more or less till the end of the week. What a different aspect the garden now wears! It is to be hoped now that the rain has come that we may have sufficient to bring on all vegetables without having to resort to the tedious, but what has been absolutely necessary where water was at command, labour of watering outdoor crops.—R. P. R.

— **INDEX KEWENSIS.**—This, which has been in the course of preparation for several years past, is "a work of supreme importance to students of botany and to horticulturists," and we think the following prospectus will interest readers:—"Now ready, part 1, pp. 728, quarto. Price to subscribers, 2 guineas net. The work will be completed in four parts, which will be issued to subscribers at 8 guineas, and the price will be raised on publication. 'INDEX KEWENSIS.'—PLANTARUM PHANEROGAMARUM NOMINA ET SYNONYMA OMNIUM GENERUM ET SPECIERUM A LINNAEO USQUE AD ANNUM M DCCC LXXXV COMPLECTENS NOMINE RECEPTO AUCTORE PATRIA UNICUIQUE PLANTAE SUBJECTIS. SUMPTIBUS CAROLI ROBERTI DARWIN. DUCTU ET CONSILIO, JOSEPHI D. HOOKER. CONFECIT B. D. JACKSON.

"The printing of part 2 is well advanced, and the completion of the whole work may be expected during 1894. The following communication from Sir Joseph Hooker, F.R.S., &c., explains the origin, plan, and purpose of this important and comprehensive undertaking:—"Shortly before his death, Mr. Darwin informed me of his intention to devote a considerable sum in aid or furtherance of some work of utility to biological science, and to provide for its completion should this not be accomplished during his lifetime. He further informed me that the difficulties he had experienced in accurately designating the many plants which he had studied, and ascertaining their native countries, had suggested to him the compilation of an index to the names and authorities of all known flowering plants and their countries, as a work of supreme importance to students of systematic and geographical botany, and to horticulturists, and as a fitting object of the fulfilment of his intentions. I have only to add that, at his request, I undertook to direct and supervise such a work; and that it is being carried out at the Herbarium of the Royal Gardens, Kew, with the aid of the staff of that establishment.—JOS. D. HOOKER." As a reference work regarding the nomenclature of plants, "Index Kewensis" will stand pre-eminent. Mr. Henry Froude, Oxford University Press Warehouse, Amen Corner, London, E.C., is the publisher.

— **MESSRS. SUTTON & SONS,** Reading, have announced to their employes that in commemoration of the Royal Wedding all departments in their business will be closed on July 6th. In addition to receiving the usual day's pay, every employe will, on the preceding day, be presented with an extra week's wages.

— **ROYAL WEDDING BOUQUETS.**—We are informed Messrs. Wills & Segar have received the Royal command to supply the wedding bouquets on the occasion of the marriage of H.R.H. the Duke of York and H.S.H. the Princess Mary of Teck. The same firm have also received instructions to decorate the Royal breakfast table at Buckingham Palace on the occasion of the Royal Wedding.

— **NATIONAL PINK SOCIETY (NORTHERN SECTION).**—This Society will hold its annual Exhibition, July 6th, in the gardens of the Manchester Royal Botanical and Horticultural Society, at Old Trafford, in conjunction with the exhibition of Roses to be held in the gardens on that date. Mr. J. W. Bentley, Stakehill, near Manchester, is the Secretary.

— **AN ECCENTRIC CURRANT BUSH.**—I have a large Red Currant bush full of fruit, and on one of the branches of which is a crop of fine White Currants. This branch of white fruit does not start from the ground, is not grafted, and is a collateral of one of the branches bearing the red fruit, so that the two kinds are really on the same branch. I should be glad to know if any of your correspondents have met with a similar curiosity.—CHAS. H. PAGE.

— **THE GREAT YORK GALA AND HORTICULTURAL EXHIBITION.**—We mentioned in our report of this Exhibition, held on the 14th, 15th, and 16th inst., that Messrs. Jas. Backhouse & Son, The Nurseries, York, had arranged an artistic Alpine garden at one end of a great tent, and the Judges recommended that a gold medal should be awarded to this excellent exhibit. We are pleased to say that the Committee decided to do this, and the recognition was well merited.

— **NOTTS HORTICULTURAL AND BOTANICAL SOCIETY'S EXCURSION TO SHIPLEY HALL GARDENS.**—The first excursion of the season of the above Society took place on June 15th. Shipley Hall, Derbyshire, the residence of Mr. E. M. Mundy, J.P., was the place decided upon, thanks to Mr. Elphinstone's kindness, and no more interesting place could there be for such an object. The weather was perfect from a holiday point of view, and some 200 gardeners and garden lovers responded to the Society's invitation. On arriving at Shipley the excursionists received from Mr. Elphinstone a hearty welcome, and the family being away from home he and his staff were enabled to show the visitors unreservedly not only over the whole gardens, but over farm and farmyard, dairy (a model in its way), park—everywhere. It was that unlimited freedom of observation and indulgent rest amongst such scenes of beauty which was the chief item in the enjoyment of the day. Tea was provided in a tent in the park, and at its close the President of the Society, the Sheriff of Nottingham (Mr. Joseph Bright) in thanking Mr. Mundy for the use of his grounds, and Mr. Elphinstone for his courteous reception, alluded to all their natural advantages, and dwelt on the excellent gardening which was shown in every part of the gardens, more especially so in the singular beauty of the indoor fernery and the magnificent Orchids.

— **LEICESTER AND MIDLAND CHRYSANTHEMUM SOCIETY.**—On Saturday, June 24th, the first (what is hoped will be annual) outing of the above Society took place under favourable circumstances. At the invitation of Thomas Brooks, Esq., the gardens of Barkby Hall were visited. Early in the day the weather seemed rather threatening, but midday it had cleared, and the bursts of sunshine added much to the prospect of a pleasant journey. About two o'clock the party left Leicester in a covered conveyance, and passed through Belgrave, Thurmaston, and Syston, where a halt was made to inspect the nurseries of Mr. W. K. Woodcock, who has done sterling service to the Society, he having been Chairman of Committee for several years, and much regret was expressed when the resignation of that office was caused by his lecturing appointments. Another pleasant drive of about a mile brought us to Barkby Hall, where Mr. Lansdell, the head gardener, was expecting us. At six o'clock the company adjourned to the Malt Shovel Hotel, where an excellent meat tea had been prepared. After tea Mr. H. Bell (the Chairman of Committee) was voted to the chair, and a discussion on Tomato growing was introduced by the Chairman, and carried on by Messrs. Lansdell, Smith, W. Bell, Johnson, and others. At nine o'clock the party started on the return journey, reaching Leicester about 10 P.M.

— CAMPANULA (PLATYCODON) GRANDIFLORA.—I saw this very fine yet not at all common Bellflower in Mr. Ladham's nursery flowering grandly in spite of the drought. The flowers are erect, of a pale mauve colour, and very pleasing. It is very hardy, and worthy of a place in every hardy flower border.—D.

— A WILD FLOWER EXHIBITION.—There was a large and comprehensive display of wild flowers at the meeting of the Wakefield Paxton Society last week, over 200 species being staged. Mr. Blackburn arranged the wild flowers most effectively. A very interesting discussion was opened by Messrs. Burton and Parkin, each of whom dilated upon the usefulness and interest attached to the study of botany.

— THE WEATHER AROUND WARWICK.—Several showers have again fallen in this district, which have already produced a marvellous improvement in the appearance of vegetation generally. Trees, grass, and crops are in many instances assuming numerous and varied tints of verdant green. This change in the weather is fully appreciated after the intense heat and arid atmosphere experienced during the previous week. Rain began to fall during the evening of Thursday, 22nd, and continued at intervals throughout the night; by the following morning a quarter of an inch had fallen. On Friday slight showers fell frequently, and continued to fall during the night. To-day (Saturday) they are of frequent occurrence, and seem likely to continue. The total rainfall during the last three days amounts to a little less than an inch.—H. DUNKIN.

#### THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—ANNUAL DINNER.

THE supporters of this old established and excellent charitable Institution held their fifty-fourth anniversary festival dinner at the Whitehall rooms, Hôtel Métropole, on Thursday, June 23rd. Baron Schröder, who is well known in the gardening world as an enthusiastic orchidist and an ardent supporter of all horticultural matters, presided over a large assembly. About 120 gentlemen were present, and the company included Lord Teynham, Sir Trevor Lawrence, Bart., N. N. Sherwood, Esq., Rev. W. Wilks, M.A. (Master of the Gardeners' Company), P. Crowley, Esq., H. J. Veitch, Esq., N. L. Cohen, Esq., John Lee, Esq., R. M. Hogg, Esq., T. F. Peacock, Esq. (Hon. Solicitor), Messrs. W. Bull, J. Laing, H. Williams, J. Cheal, H. B. May, Owen Thomas, G. Munro, A. Turner, A. W. G. Weeks, G. Paul, H. Ballantine, A. Moss, Drewett, Rivers, A. Baker, A. F. Barron, J. Walker, J. Douglas, J. Hudson, G. J. Ingram (Secretary), and many other horticulturists and their friends.

The Chairman, after the customary loyal toasts, proposed the toast of the evening—namely, that of "Continued Success and Prosperity to the Gardeners' Royal Benevolent Institution, coupled with the name of H. J. Veitch, Esq., Treasurer." In his introductory remarks, the Chairman remarked that when he was asked to preside on this occasion he was at first inclined to refuse the honour put upon him because he felt he was no orator. However, he was deeply interested in the Institution and determined to give his testimony on its behalf. He took a great interest in all things connected with horticulture, and he was sure his hearers would forgive any shortcomings on his part that evening. Despite the number of hospitals in that vast metropolis, and charitable societies innumerable, there were none that spoke so much to the heart as the Gardeners' Royal Benevolent Institution (hear, hear). The man did not exist who was not fond of flowers. They were mankind's companions alike in joy and sorrow. The associations of flowers went with them through all the circumstances of life. As children they were taught the love of flowers; young men when they go into society must have their flowers as buttonhole bouquets; and the young maiden, before she has discovered diamonds, is charmed with beautiful flowers. At matrimonial ceremonies, too, flowers were always in evidence. The happy home is usually bedecked with floral gems, and when at his (the speaker's) age, there was nothing so soothing as to go into the greenhouse and see the beautiful plants (cheers). He might go further, and say that flowers followed mankind to the grave, and he considered them as our best friends. If this was their regard for flowers, what ought to be their feelings to those who tended their flowers with loving hands night and day at the risk of their health—their gardeners? Ought they not to honour these men? Ought they not to do everything in their power to assist them in their old age, and to alleviate their sufferings? Therefore those present ought to be thankful that the Gardeners' Royal Benevolent Institution gave them the opportunity of showing their gratitude to those who had grown their fruits and flowers. The Institution, as they all knew, was established in 1838, and two years afterwards he understood there were two pensioners and 100 subscribers. At the present day there were 150 pensioners and 1300 subscribers. The Institution numbered amongst its distinguished patronesses and patrons Her Most Gracious Majesty the Queen and the Prince of Wales. The late Prince Consort had been for a long time a patron of the Institution. In his opinion he thought it was the duty of that assembly to show to the world that they were not only horticulturists, but also philanthropists; and that they were anxious

not only to grow the finest flowers that were to be found in the world, but that they could show at the same time they appreciated the labours of their gardeners (hear, hear). One noticeable feature of the Institution was the encouragement it gave to those gardeners who in their days of prosperity subscribed to its funds. He thought that the new Rule 10 was one of the best rules that he had ever seen in any charitable institution. This rule, which was incorporated last year, gave a gardener who had been a subscriber four years no less than fifty votes at an election, while subscribers over a longer period had still greater privileges. In conclusion, the Chairman made an eloquent appeal on behalf of the recipients of the pensions provided by the Institution, and he trusted that the results of that evening's proceedings would be a considerable augmentation to the subscription list (applause).

Mr. H. J. Veitch, in responding, observed that he had seldom listened to a more sympathetic speech with regard to the Institution's work at its festival anniversary. (Hear, hear). In looking back over the affairs of the Institution since it was founded, he thought its friends had great cause for congratulation that during the whole fifty-five years they could point to a continued progress, and even in these days of hard times he was still glad to say that the Institution fully maintained its position so far as the keeping up of the number of its pensioners was concerned. Although he could not point to any increase in the subscription list during the past year, still a gratifying reduction had been made in the working expenses. When he reminded those around him that Mr. John Lee, the father of the Institution, seldom failed to preside over its meetings, they might rest assured that every economy would be practised in its management. (Hear, hear). They owed a debt of gratitude to Mr. Peacock, their honorary solicitor, who so unstintingly gave his ability in framing the present rules of the Institution. He claimed that the rules of the Gardeners' Royal Benevolent Institution were now second to none. The pension list of the Society required the expenditure of the sum of £2700 annually. The fixed income was, however, only about £2000, so that the absolute need and great necessity of a spirited response to the Chairman's appeal would be manifest. He might lay stress on the fact that the pensioners of the Institution were scattered throughout the United Kingdom without regard to nationality or creed, some being in Scotland, Ireland, and Wales, as well as in England. The general rules provided that pensioners should not be eligible for election under sixty years of age, but they had the power to make exception to this. There were now four such cases, and of these one poor gardener was blind, and another suffering from brain disease. He had received many letters appealing for help, and it was sad to think that there were twenty-five unsuccessful candidates at the last election of pensioners. He asked for means to aid the needy, and then the benevolent would know that they were doing good. (Cheers).

Sir Trevor Lawrence, Bart., in response to the toast of "The Royal Horticultural, Royal Botanic, and Kindred Societies of the United Kingdom," which was briefly submitted by Mr. Moss, in the unavoidable absence of Dr. M. T. Masters, F.R.S., said that he had been connected with the Royal Horticultural Society for a long time. The Society had seen dark days, but he was thankful to say that it had emerged from them. There were now about 3000 Fellows, and they were apparently well satisfied with what they were receiving in exchange for their subscriptions. Moreover, recruits were coming in from all over the country, and no less than 274 new Fellows have already been elected this year. The Exhibition in the Inner Temple Gardens was a success from every point of view. It was a success naturally, and a most distinguished horticultural success, and many friends had told him that a more beautiful show they had never seen. He and others present had seen a good show at Ghent, and they wished an opportunity would arise to enable them to reciprocate the kind feeling that had been accorded to them there. Horticulture in Belgium was, however, on a different footing to what it was in England. Here horticulturists get "a cold shoulder" from every department of the state. (No, no). Someone said "no, no," but he maintained that he was right. However, the Royal Horticultural Society did all that was possible in disseminating a knowledge of horticulture, as in addition to the volumes now published regularly at intervals, there was the report of the Conifer Conference—a book of 600 pages—which he regarded as one of the best of works on the subject. Examinations in horticulture for garden scholarships had been held, and this year there were 204 candidates, seventy-six of the higher grade, and 128 of the lower grade. They would be glad to hear that that afternoon he had received an intimation that the Somerset County Council would be happy to co-operate with them in regard to these and similar examinations. (Hear, hear). He thought it was very gratifying to know that nearly every new plant made its *début* at one of the fortnightly meetings of the Royal Horticultural Society, which proves that the Society was in every way connected with horticulture. He expressed regret at the unfortunate results of the efforts to establish an Horticultural Hall, but he did not despair in that respect. Regarding the claims of the Institution he remarked that the debt of gratitude employers owe their gardeners is enormous, and he hoped his hearers would respond liberally to the Chairman's eloquent appeal. (Cheers).

The Rev. W. Wilks, M.A., proposed "The Stewards and Officers, coupled with name of N. N. Sherwood, Esq.," and in doing so remarked he was sure they would forgive him if he began at the bottom. They all knew what an excellent Secretary they had in Mr. Ingram. The Stewards he considered as kind friends of the Institution, inasmuch as they all worked very hard at their task. As proof of this he might mention that one of them, Mr. Munro, had collected nearly £100, and others had made strenuous efforts to augment the subscription list. Mr. Veitch,

too, was well known for his generosity, and Mr. Sherwood's name was a household word among gardeners throughout England. Mr. Sherwood was always to the fore ready to help with his head and his purse. (Cheers).

Mr. Sherwood, in responding, said he could endorse what Mr. Wilks had spoken with regard to their Secretary. It would have been a very difficult matter to have found another gentleman more fitted for the post than Mr. Ingram. (Hear, hear). It must give them all great pleasure to see Mr. John Lee there that evening. So long as he personally was prosperous he would be always endeavouring to aid this most excellent Institution. (Applause).

Mr. A. W. G. Weeks, in submitting "Our Chairman," observed that they were deeply indebted to Baron Schröder for coming there that evening. For his munificence in the past the Chairman was well known among horticulturists, and as regards his admiration for flowers, they had ample evidence of this in that earthly paradise The Dell, where many beautiful Orchids were to be seen. Baron Schröder briefly responded, amidst much cheering.

Mr. G. J. Ingram, the Secretary, announced the total of the evening's donations as £1454. The subscriptions included Baron Schröder, 50 guineas; Baroness Schröder, 50 guineas; Messrs. Rothschild & Sons, 100 guineas; Mr. N. N. Sherwood, £100; Mr. G. Monro, £91; Sir T. Lawrence, Bart., 10 guineas; Mr. H. Williams, £35; Messrs. J. Veitch and Sons, 20 guineas; Mr. W. Bull, £13; the Vintners' Company, 10 guineas; the Merchant Taylors' Company, 10 guineas; Mr. Alma Tadema, 10 guineas; Mr. N. L. Cohen, 10 guineas; Mrs. Paine, 10 guineas; Mr. J. H. Sykes, 10 guineas; Mr. T. Peed, 10 guineas; Messrs. Protheroe & Morris, £12; Mr. G. F. Wilson, 10 guineas; Mr. T. B. Haywood, 10 guineas; and numerous other sums from various subscribers.

Between the toasts a choice selection of music was rendered, under the direction of Mr. Herbert Schartau, by Miss Teresa Blamy, Miss Carrie Curnow, Mr. Herbert Grover, and Mr. Robert Grice.

#### ROYAL BOTANIC SOCIETY'S FLORAL FÊTE.

As briefly announced in our last issue a children's Floral Fête was held in the gardens of the Royal Botanic Society, Regent's Park, on Wednesday, June 21st. The idea of this annual event is to imitate, so far as our climate will permit, the floral carnivals at Cannes and other places in southern Europe, and success has been attained. Fortunately on this occasion fine weather prevailed, and owing to the Duke and Duchess of Teck with H.S.H. Princess May being present, a large and fashionable assembly witnessed the parade. There were many mail carts, tastefully decorated with flowers and drawn by children, the first prize in this class going to one covered with Lilies by Mrs. White. Others were embellished with yellow Marguerites, Roses, Sweet Peas, and blue Cornflowers. A goat chaise decorated with Lilies, Roses, and Marguerites, well blended by Mr. East, secured a leading prize, as also did the sedan chair covered with Marguerites by Mr. Youens. Sir Augustus Harris and Lady Harris, who officiated as Judges, considered this as being the best of the exhibits; and there were many ponies, goats, and mail carts, all beautifully decorated with flowers of various kinds, and the whole presented a pretty sight. The only thing that appeared lacking was more greenery amongst the flowers, and that should be of a stout nature.

The great exhibition tent was erected for the purpose of accommodating the group of plants, cut flowers and window boxes, for which prizes were offered. Comparatively few exhibitors, however, put in an appearance. Messrs. W. Paul & Son, Waltham Cross, sent a beautiful collection of cut Roses, also some plants in pots. The former were shown in huge bunches and in boxes. The new Rose Clio was in splendid condition, and the same may be said of Spencer. L'Idéal, Maréchal Niel, Madame Hoste, W. A. Richardson, and Grand Duke Luxembourg were also very fine. A certificate was awarded for the last named, which is a splendid high coloured Tea-scented variety. A small silver-gilt medal was awarded Messrs. Paul & Son for their contribution. Mr. G. Mount, Canterbury, also sent a dozen boxes of cut Roses, amongst which were some splendid blooms of Maréchal Niel, Comtesse de Nadaillac, Innocente Pirola, and Marie Baumann (silver medal). Mr. Frank Cant, Colchester, secured a silver medal for some cut Roses, fresh and beautiful, especially Madame Cusin, Souvenir d'Elise, Marie Baumann and Ernest Metz.

Messrs. J. Laing & Sons, Forest Hill, were awarded a small silver-gilt medal for a magnificent group of flowering and ornamental foliaged plants. These were arranged with admirable taste, and comprised Orchids, Begonias, Caladiums, Dracenas, Palms, Ferns, Crotons, and other plants. Certificates were awarded for Begonias Countess of Craven (white) and Sir John Lennard, a splendid rich crimson double variety. Mr. R. Box, Croydon, sent a group of Caladiums, also Begonia blooms, for which a large silver medal was awarded. Certificates were given for Caladiums J. Laing and Lymington, and also for Begonia W. Phelps. Mr. C. Turner, Slough, had a group of Souvenir de la Malmaison Carnations and Crimson Rambler Rose, and a silver medal was recommended. Mr. R. Scott, gardener to Miss Foster, The Holmes, Regent's Park, was awarded a silver medal for a group of plants; and Mr. J. R. Chard, Stoke Newington, for table decorations. Mr. H. O. Garford, Floral Dépôt, Stoke Newington, gained a large bronze medal for a window box filled with plants tastefully arranged, and another bronze medal for two baskets of plants.

#### STYLOPHORUM DIPHYLLUM.

THE Celandine Poppy, though it has been in cultivation in this country for about forty years, is still an uncommon plant in our gardens. It is a hardy herb with a perennial rootstock, and has a considerable resemblance to *Chelidonium majus*, to which, however, it is much superior. It attains a height of 1 foot or 18 inches. The foliage is deeply pinnatifid, soft in texture, greyish-green above, and glaucous beneath. The flowers are freely produced in May and June; they are about 2 inches in diameter, and of a deep yellow colour. The plant is quite hardy, and will thrive in any light garden soil. It is easily raised from seed, and can be increased by division of the rootstock. It is a native of North-west America.

The illustration (fig. 93) was prepared from a plant which flowered recently in the alpine house at Kew. *S. japonicum*, the only other

FIG. 93.—STYLOPHORUM DIPHYLLUM.

species in cultivation, is sometimes confounded with *S. diphyllum*, but it is quite distinct. It is a native of Mandschuria and Japan.—A. B.

#### THE GUNTON PARK STRAWBERRIES.

MR. W. ALLAN kindly sent me a few days since some fruits of his fine new Strawberries. They travelled the long journey between here and Gunton admirably, turning out as bright and fresh as if just gathered; the bed of moss and the top layer of leaves of *Ampelopsis Veitchi* seemed to keep the fruits so cool. Then what an advantage is it in determining the merits of a fruit to be able to have enough of it. At the Fruit Committee meetings one has often to judge from eating half a Strawberry. That satisfies no one; but when it is possible to taste several, going over the respective sorts and coming back to the course again, then is a practical estimate as to flavour and other merits obtained.

The smallest fruits, those of Empress of India, have in them much of the old Pine flavour, the flesh soft and smooth, and a beautiful scarlet

colour—my favourite hue in the Strawberry. This is, I think, *par excellence* a high-class dessert variety, and is specially a ladies' Strawberry. Lord Suffield has firmer flesh, is long and tapering, of a rich crimson hue, flavour of a vinous kind; a delicious variety. Gunton Park gives large, flattish, somewhat cockscomb-shaped fruits of a rich deep blood crimson colour, flesh very firm, of striking flavour, but slightly acid. This should, especially that it is a great cropper, make a fine market variety. As Strawberries vary so much on diverse soils, it will be well if growers will get plants and give the sorts a good trial. Most certainly Mr. Allan has been more fortunate than the majority of raisers in hitting upon a fine vein of flavour.—A. DEAN, *Kingston*.

### RECORDS FOR EARLY PEACHES.

I GATHERED the first fruit of Alexander from a tree growing against a south wall on June 24th. From the same tree the first fruit was picked July 25th last year, which shows the extreme earliness of the present season. With us this Peach out of doors never fails to give a full crop of fruit; in fact we find it necessary to relieve the trees of more than half of those that set. The colour of the fruit is invariably high and the flavour good for the variety. All who value early outdoor Peaches should grow this sort.—E. MOLYNEUX, *Hants*.

SEEING in the *Journal of Horticulture* (page 500) that Mr. W. Iggulden gathered ripe fruit of the Alexander Peach from a tree growing against a south-east wall on the 18th inst., I write to say that I gathered excellent fruit of the same variety from a tree on a south-west wall and close to one of our forcing houses on the 16th inst. The tree is a large one for the variety, and is now (June 23rd) nearly cleared of the crop for this year.

The next earliest Peach out of doors here is Waterloo, on the same wall as the Alexander. It was ripe on the 21st. The fruits are not so large as those of Alexander but are of better quality, and, like it, very highly coloured. Amsden growing against a south wall will be ripe in the course of a few days. The fruit is of moderate size, highly coloured, of excellent quality. Following closely is Hales' Early, a first-rate early Peach as regards size, colour and flavour, but later than those varieties mentioned above ripening its fruit.—H. W. WARD, *Longford Castle, Salisbury*.

### ROSE SHOW FIXTURES IN 1893.

- June 29th (Thursday).—Eltham and Sittingbourne.  
 July 1st (Saturday).—Crystal Palace (N.R.S.).  
 „ 4th (Tuesday).—Bagshot, Diss, and Gloucester.  
 „ 5th (Wednesday).—Croydon, Ealing, Farnham, Hereford, and Lee.\*  
 „ 6th (Thursday).—Bath, Farnham, Manchester, and Norwich.  
 „ 7th (Friday).—Ulverston.  
 „ 11th (Tuesday).—Harleston and Wolverhampton.†  
 „ 12th (Wednesday).—Earl's Court and Tunbridge Wells.  
 „ 13th (Thursday).—Worksop (N.R.S.), and Woodbridge.  
 „ 14th (Friday).—Helensburgh.  
 „ 15th (Saturday).—New Brighton.  
 „ 20th (Thursday).—Bedford and Trcntham.  
 „ 25th (Tuesday).—Tibshelf.  
 „ 27th (Thursday).—Halifax and Southwell.  
 „ 29th (Saturday).—Bedale.

\* Shows lasting two days.

† Show lasting three days.

—EDWARD MAWLEY, *Rosebank, Berkhamsted, Herts*.

### STRAY NOTES.

THE following is a pleasing sensation. You arrive at your first show of the season, with no time to look round and see the state of affairs and what chance you have, but must begin setting up at once. As you do so, behind your back pass certain strollers, and some of these are as good critics as you could wish, and excellent reflections of the state of things in the present show. The first one says nothing, but he stops (it is a good sign, you are not altogether out of it; unless of course you are bad enough to be worth contemplation); presently another and another, and they all stop; you catch a muttered comment, "Some weight there!" and your ardour and confidence (and fumbling in my case) increase. At last an acquaintance comes by, "Hullo! R., where did you get those?" It does not sound complimentary, but it is good enough for you; the first prize is at all events within measurable distance, if not yet won. At the Westminster Tea Rose Show there seemed to be an unusual number of wandering Peris without their Rose boxes as qualifications for entering the rosarian Paradise of competition; but, sad though their case was, they certainly showed no jealousy, but were as happy in helping and congratulating the successful candidates as if they had won themselves. May it ever be so, as I believe it will.

It was certainly a revelation to me, who had not realised the widespread disaster to the Rose shows of 1893 from the drought and heat, to hear the universal report. Teas all over. H.P.'s over or worthless. Stocks nearly all dead. Cuttings in almost the same plight. The strangest part of it is that cut-backs seem to have done better than maidens, whose growth has been very poor. Dwarf maidens, whose strong far-reaching young roots one would have thought of greater power than those of cut-backs, have not stood the ordeal nearly so well. Standard maidens have done better, and standard maiden Teas look well. This is a puzzle; probably standard stocks are taught by Nature to root more deeply, as a hold against the wind. The outlook for next winter is serious, for the necessities of life such as Rose plants and Briar cuttings, not to mention hay and such trifles, are likely to be scarce and dear; but, at present, how to show thirty-six blooms three days running at local shows in July is the problem which is exercising the brains of East Anglian amateurs.

One great disadvantage of such an abnormal season is that in many cases no certain judgment can be passed on new Roses which we have not seen before. Gustave Piganeau and Mrs. Paul I have had good enough for any season, but I can find no excuse for Margaret Dickson, which on the strongest of maidens and cut-backs is distinctly not so good with me as the average of Merveille de Lyon. Here is another mystery, for the failure is not confined to my plants, and the fact that Messrs. Dickson have shown it particularly full in the centre, and that it is decidedly weak in that point with me and others, remains unaccounted for. I have had a good bloom or two of Salamander, and a prettily coloured one of the Duchess of Fife. The Duke of Fife has not been strong enough with me at present to differ very much in colour from Etienne Levet. Ethel Brownlow is coming stronger and better every year, and taking rank among the very best of the Irish Roses.

Of some new Roses seen lately at Mr. B. Cant's, I liked best La Fraicheur (Pernet et Ducher) which I suppose is a Hybrid Tea, pink, long-petalled and very promising, and Spenser (W. Paul & Son) H.P., which at first sight resembles Baroness Rothschild, but looks as if it might be fuller, and if so will be decidedly valuable. Mrs. Harkness shown at Westminster looks as if it might be good under favourable circumstances, but Merrie England appears in a harlequin costume, which does not look good taste. I wish some microscopical expert could have examined the base of the one shoot of the plant of Heinrich Schultheis which produced both these remarkable variations at Messrs. Harkness' nursery (the one being soft pink, and the other darker and splashed with white after the manner of Pride of Reigate), as it is surely possible that in these days something might be found out as to the cause of sports; and it would be a great thing if we could inject a sport microbe or bacillus into a shoot so as to produce such variations at will.

I forgot to mention last week one serious insect pest—thrips, which are always rampant here in a dry time, though in some places they seem unknown out of doors. They have spoiled many buds of Teas and La France with me and others, and have ruined my standard Teas from which I hoped much. I know of no remedy but syringing, though of course this must not be used when the buds are advanced.—W. R. RAILLEM.

### HORTICULTURAL SHOWS.

#### HITCHIN.—JUNE 26TH.

THIS annual Exhibition of Roses, herbaceous flowers, greenhouse plants, fruit and vegetables, was held on Monday, June 26th, in the Grammar School grounds. Despite the abnormally dry weather which has been experienced the Roses were of exceptionally good quality, almost equal to those of last year, and the number of competitors showed an appreciable increase. The arrangements of the Show reflect much credit on the Committee of Management and on Mr. W. G. P. Clark, the indefatigable and courteous Assistant Secretary. A list of the prizewinners in the Rose classes is appended, but space does not permit a detailed report of flowers, fruit, and vegetables, which were shown in excellent condition.

For forty-eight Roses, distinct, single trusses, Messrs. Harkness & Son were awarded the first prize, their stand being a magnificent one. The blooms were of fine substance, good shape, and well coloured. The varieties staged were Gustave Piganeau, Mrs. J. Laing, Chas. Lefebvre, Margaret Dickson, Camille Bernardin, Marie Fänger, Star of Waltham, François Michelon, Senateur Vaisse, Madame Cusin, The Bride, A. K. Williams, Souvenir d'Elise, Catherine Mermet, Fisher Holmes, May Quennell, Duchess of Bedford, Viscountess Folkestone, Jean Lelièvre, Mrs. Harkness, Countess of Rosebery, Duchesse de Morny, Ulrich Brunner, Lady Mary Fitzwilliam, Duke of Fife, Marquise de Castellane, Madame Wood, La France, Alphonse Souper, Prince Arthur, Heinrich Schultheis, Caroline Kuster, Comte Raimbaud, Boule d'Or, Etienne Levet, Jean Ducher, Dupuy Jamain, Princess Beatrice, Suzanne Marie Rodocanachi, Merveille de Lyon, Crown Prince, Merrie England, Victor Hugo, Francisca Kruger, Marie Verdier, and Margaret Boudet. Mr. Frank Cant, Colchester, was accorded the second prize for an exceptionally good stand; Messrs. G. and W. Burch, Peterborough, were third; and Messrs. Geo. Paul & Son, Cheshunt, fourth.

In the classes for members of the Society E. B. Lindsell, Esq., Bearton, Hitchin, was awarded the first prize in the class for twenty-four distinct varieties of Roses, single blooms of each, showing the following in almost

perfect form :—Horace Vernet, Mrs. J. Laing, Louis Van Houtte, Prince Arthur, A. K. Williams, Her Majesty, Marie Baumann, Duke of Edinburgh, Ulrich Brunner, Merveille de Lyon, Abel Carrière, François Michelon, Chas. Lefebvre, Caroline Kuster, Suzanne Marie Rodocanachi, Prince Camille de Rohan, Dupuy Jamain, Lady Helen Stewart, Duke of Wellington, Lady Dufferin, Lord Dufferin, Dr. Andry, Duchess of Bedford, and Alfred Colomb. J. Gurney Fowler, Esq., Glebelands, South Woodford, was second with a very good stand ; and H. V. Machin, Esq., Gateford Hall, Worksop, was a close third. The competition in this class was especially keen, the entries all being of good quality.

In the class for twelve Tea or Noisette Roses, in distinct varieties, Mr. Jas. Parker, Oakfield, Hitchin, was first with Marie Van Houtte, Boule d'Or, Catherine Mermet, Innocente Pirola, Hon. Ethel Brownlow, Madame Lambard, Francisca Kruger, Anna Ollivier, Madame de Watteville, Souvenir de Paul Neyron, Comtesse de Nadaillac, and Madame Cusin. This was a really excellent stand. E. B. Lindsell, Esq., was second with a fine exhibit, and the Rev. W. H. Jackson, Stagdon Vicarage, Bedford, third. The first prize, which included the N.R.S. silver medal, for twelve distinct Roses was awarded to W. O. Innes, Esq., Hitchin, who exhibited well finished examples of Her Majesty, Beauty of Waltham, Ulrich Brunner, Rosieriste Jacoby, Maréchal Niel, Duke of Wellington, Madame Chas. Crapelet, Dr. Sewell, Horace Vernet, Prince Arthur, Chas. Lefebvre, and Alfred Colomb. Mr. Geo. Moules, Hitchin, was second with a collection which would in many shows have been worthy of the premier position. Mr. J. Bateman, Archway Road, Highgate, was third ; and Miss Bailey Denton, Orchard Street, Stevenage, fourth.

A. W. Lines, Esq., Hitchin, was an easy first in the class for nine Roses, distinct, showing Etienne Levet, Her Majesty, Alfred Colomb, Horace Vernet, Fisher Holmes, Innocente Pirola, Duke of Edinburgh, Souvenir d'un Ami, and Francisca Kruger ; the second prize going to A. Ransom, Esq., Benslow, Hitchin. In the class for six Tea or Noisettes, distinct, Mr. George Moules was an excellent first with Maréchal Niel, Jean Ducher, Souvenir d'Elise Vardon, Innocente Pirola, Madame Lambard, and Souvenir d'un Ami. Charles J. Grahame, Esq., Coombe Road, Croydon, was second with a very good stand indeed ; and W. O. Innes, Esq., third. The bronze medal of the N.R.S. and the first prize for six distinct Roses were taken by Mr. Leonard Moules, Orton Head, Hitchin, who staged E. Y. Teas, Her Majesty, A. K. Williams, Duke of Edinburgh, Duke of Teck, and Alfred Colomb. William Kingston, Esq., Grove Place, Bedford, was second ; and W. Hill, Esq., Hitchin, third.

E. B. Lindsell, Esq., was awarded the first prize for six blooms of any Hybrid Perpetual, staging beautiful examples of Mrs. John Laing ; H. V. Machin, Esq., was second with the same variety, and the Rev. W. H. Jackson third with Victor Verdier. In the class for six blooms of any Tea or Noisette, H. V. Machin, Esq., was first with charmingly coloured and excellently finished blooms of Souvenir de S. A. Prince, Mr. Jas. Parker being second, and the Rev. W. H. Jackson third with Marie Van Houtte. The first prize in the class for six distinct Roses, open only to those who had not previously won a prize for cut Roses from any society, was accorded to Mr. C. Norris, 17, Bedford Street, Hitchin. The bronze medals offered by the N.R.S. for the best Tea bloom and the best Hybrid Perpetual were taken by Mr. Jas. Parker with A. K. Williams in the latter, and by the Rev. W. H. Jackson with Comtesse de Nadaillac in the former.

In the class for thirty-six bunches of hardy perennial or bulbous rooted plants in distinct varieties, Messrs. J. Burrell & Co., Howe House Nurseries, Cambridge, were accorded the first prize for a grand exhibit. Amongst the most prominent flowers in this stand were Alstromerias, Lilliums, Delphiniums, and Iceland Poppies. Messrs. Harkness & Son, Grange Nurseries, Bedale, took the second prize with a very creditable collection, Messrs. Laxton Bros., Bedford, being placed third. The competition was keen, each of the stands being very good.

#### SUTTON.—JUNE 27th.

THE annual Rose Show of the Sutton Amateur Rose Society was held in the Public Hall of that town on Tuesday, June 27th. The Exhibition was a most creditable one, and admirably arranged by the Committee and the energetic Secretary, Mr. Ernest Williams. One of the finest exhibits was a box of Comtesse de Nadaillac Roses, staged by the Rev. F. R. Burnside. Table decorations were a feature and a good one, Mrs. Ernest Wilkins being a successful competitor, as also was Mrs. O. G. Orpen in the classes for bouquets and baskets, her exhibits being the essence of grace and beauty, and denoting on the part of the lady a really admirable taste.

In the class for thirty-six distinct Roses, one bloom of each, and open to all nurserymen, Mr. B. R. Cant, Colchester, was deservedly awarded the first prize. This stand included Duke of Edinburgh, Countess of Oxford, Merveille de Lyon, Alfred Colomb, Mrs. J. Laing, Suzanne M. Rodocanachi, Gustave Piganeau, Annie Wood, Madame de Watteville, Charles Lefebvre, Her Majesty, Dr. Andry, Reynolds Hole, John Stewart Mill, Maréchal Niel, Innocente Pirola, Abel Carrière, Madame Cusin, Général Jacqueminot, Ernest Metz, Comte Benoit, The Bride, A. K. Williams, Madame C. Joigneaux, Dr. Sewell, Thos. Mills, Baroness Rothschild, Maurice Bernardin, Madame Hoste, Marie Verdier, Victor Hugo, Catherine Mermet, Fisher Holmes, Prince Arthur, and Dupuy Jamain. Mr. Frank Cant, Colchester, was an excellent second ; and Messrs. Geo. Paul & Son, Cheshunt, third.

In the class for twelve Teas or Noisettes in distinct varieties, Mr. B. R. Cant was again first, staging exquisite examples of Madame de

Watteville, Madame Hoste, Niphetos, The Bride, Souvenir d'Elise, Ernest Metz, Comtesse de Nadaillac, Maréchal Niel, Souvenir d'un Ami, Kaiserin Frederick, and Souvenir de S. A. Prince, Mr. Frank Cant being second with a beautiful stand, and Mr. Mount, Canterbury, third. The only competitor in the class for eight varieties of Roses, three trusses of each, was Mr. A. Slaughter, who was accorded the first prize. This stand included, amongst others, Général Jacqueminot, Fisher Holmes, A. K. Williams, and Prince Arthur in good condition. Rev. J. H. Pemberton was first in the class for twenty-four distinct Roses, showing Madame Raimbaud, Sir Rowland Hill, John Stewart Mill, and others. Mr. J. G. Fowler was second, and Mr. J. Slaughter third. In the class for twelve distinct Teas or Noisettes the Rev. F. R. Burnside was first, Caroline Kuster, Marie Van Houtte, and Souvenir de S. A. Prince being amongst his best. Mr. Mease, gardener to A. Tate, Esq., Leatherhead, and Mr. A. Slaughter were second and third in the order named.

Mr. W. F. Hughes won the ladies' challenge cup and the N.R.S. silver medal, showing Madame Victor Verdier, Mrs. J. Laing, Maurice Bernardin, Reynolds Hole, Dupuy Jamain, and Prince Camille de Rohan in fine form ; Mr. W. Hooper being second, and taking the N.R.S. bronze medal. Mr. R. W. Miller third. Mr. E. Wilkins was accorded the N.R.S. bronze medal for the best Hybrid Perpetual in the local classes for a perfect bloom of Horace Vernet.

Amongst the other successful competitors may be mentioned Mr. O. G. Orpen in the class for twelve distinct Roses ; Mr. W. Colin Romaine for six distinct Roses, three blooms of each ; Mr. M. Hodgson for nine Roses in distinct varieties, one bloom of each ; Mr. A. C. Gifford for six blooms in distinct varieties ; Mr. C. J. Grahame in the class for four distinct Roses, three trusses of each ; Mr. J. Bateman for six distinct Tea or Noisette Roses. In the class for twelve blooms of any one variety the Rev. F. R. Burnside was successful with Comtesse de Nadaillac, Mr. R. W. Miller was first for six trusses of any one Rose with Maréchal Niel, and Mr. Chadburn in the class for three Hybrid Perpetuals. Mr. F. D. Young, Roselands Nurseries, Eastbourne, staged a beautiful collection of cut Roses, "not for competition," as also did Messrs. Geo. Paul & Son.

#### CANTERBURY.—JUNE 26TH.

THE fifteenth annual Show was held at the Foresters' Hall, Canterbury, on Monday, June 26th. In spite of the unfavourable weather of late the Exhibition was a very good one. Mr. R. E. West, Mr. F. Warde, and Rev. H. Biron were unable to show, their Roses being over ; and Capt. Lambert, to the deep regret of all, was kept away by a severe domestic affliction. It was a matter of agreeable surprise that the flowers were so good, and the competition so keen.

The nurserymen's classes were not well filled, but the flowers were excellent. For thirty-six distinct varieties, Mr. Frank Cant was first with—Back row : Mrs. J. Laing (excellent), Duke of Edinburgh, The Bride, Duke of Connaught, Marie Baumann, Général Jacqueminot (fine), Ernest Metz, Louis Van Houtte, Marie Verdier (good), Merveille de Lyon, and Duke of Teck. Second row : Lady Helen Stewart (good), Madame Hippolyte Jamain (Tea, first rate), Chas. Lamb, Maréchal Niel, Prince Camille de Rohan (good), Souvenir d'un Ami, Victor Hugo, Innocente Pirola, Horace Vernet, Comtesse de Nadaillac, A. K. Williams (good), and Ethel Brownlow. Front row : Baroness Rothschild, Madame G. Paul, Dr. Sewell, Pride of Waltham, Auguste Rigotard, Comte Raimbaud (fine), Souvenir de Paul Neyron, Beauty of Waltham, Souvenir d'Elise, Dupuy Jamain, Prince Arthur, and Madame Chas. Crapelet (good). Mr. Mount, Rose Nurseries, Canterbury, was an easy second, his best flowers being A. K. Williams, Marie Baumann, Dr. Andry, Louis Van Houtte, and La Rosière. For twelve trebles there was a very close competition, Mr. F. Cant being first. His best were A. K. Williams, Prince Camille de Rohan, Baroness Rothschild, and Reynolds Hole. Mr. Mount, however, ran him very close, showing grand examples of Marie Baumann and Fisher Holmes. For twelve Teas Mr. Mount was easily first, showing Innocente Pirola, Caroline Kuster, Souvenir de S. A. Prince, and Niphetos in superb form. Mr. F. Cant was second, and Colonel Pitt third.

In the members' classes Colonel Pitt was an easy first with clean and solid blooms of Madame V. Verdier, Merveille de Lyon, Thomas Mills, Alfred Colomb (good), Marie Rady, Camille Bernardin (fine), Marie Baumann (grand), Duchess of Bedford, Duke of Wellington, Emilie Hausberg, Mons. Boncenne, Countess of Oxford, Baroness Rothschild, Pierre Notting, Lady Arthur Hill, Dr. Andry, Beauty of Waltham, and Comtesse de Paris. Mr. Stonley was second, and Mr. Cooper Wachter third. For six trebles Col. Pitt was again first, showing Camille Bernardin and Emilie Hausberg in grand form. Mr. Stonley was second, and Mr. R. L. Knight, third.

For twelve varieties, Col. Pitt was first ; Mr. H. Foster, second ; and Captain Christy, third. In Section B the exhibits were very good. Rev. J. R. Buchanan being first with Gloire Lyonnaise as we seldom see it. Miss Hawksworth was second ; and Mr. Honeyball (whose exhibits show great promise of future success) third.

For six Teas Rev. J. R. Buchanan was again first with a charming box, Marie Van Houtte, Madame Lambard, and Comtesse de Nadaillac being especially fine. In the smaller classes the chief prizetakers were Mr. B. Smith of Bifrons, Dr. Selby of Teynham, Mr. Honeyball, Mr. S. A. Smith, and Mr. D. Amos.

For six of one variety Mr. Cooper Wachter was first with fine blooms of La France. The same gentleman was first for twelve Teas in the members' class, Section A. The ladies had an opportunity of showing their taste in arrangement, in the somewhat novel form of a soup plate and soda water tumbler. Mrs. Cooper Wachter decorated with her

accustomed taste, and was a good first, followed, however, by a tasteful arrangement by Miss Pilch. Altogether the Exhibition was far beyond expectation, and it is only to be regretted that the general public show so little interest in the Queen of Flowers. May the Exhibition, now of long standing, go on and prosper.

In the amateurs' class for eighteen varieties, Colonel Pitt, Turkey Court, Maidstone, was first, showing Madame V. Verdier, Merveille de Lyon, Thomas Mills, A. Colomb, Marie Rady, Camille Bernardin, Marie Baumann, Duchess of Bedford, Duke of Wellington, Emilie Hausburg, Countess of Oxford, Baroness Rothschild, and Comte de Paris. Mr. J. Stonley, Canterbury, was second, best blooms Thomas Mills; and Mr. Cooper Wachter, Hoath, third, showing good blooms of Comtesse Nadaillac, A. K. Williams, Fisher Holmes, and Marie Baumann. For twelve varieties Colonel Pitt, Maidstone, was first; Mr. H. Foster, Ashford, second; and Captain Christy third. For nine Teas or Noisettes Mr. Cooper Wachter was first, Mr. J. Stonley second, and Colonel Pitt third, the best blooms in first prize box being Madame Cusin, Ernest Metz, Madame de Watteville, and Thérèse Levet. For six varieties, three blooms of each, Colonel Pitt was first, Mr. J. Stonley second, and Mr. R. L. Knight third, the best blooms being Camille Bernardin, Marie Baumann, Dupuy Jamain, and Marie Rady.

In the class for nurserymen only, thirty-six varieties, distinct, Mr. Frank Cant was first, the best blooms being Mrs. J. Laing, Marie Baumann, Gen. Jacqueminot, Baroness Rothschild, Auguste Rigotard, Victor Hugo, and Comte de Raimbaud. Mr. George Mount was a close second, showing grand blooms of Marie Baumann, Horace Vernet, Her Majesty, Alfred Colomb, Reynolds Hole (superb bloom), Louis Van Houtte, A. K. Williams. Mr. F. Cant was first for twelve varieties, three trusses of each, best blooms including Mrs. John Laing, Marie Baumann, A. K. Williams, Reynolds Hole. Mr. George Mount was second. In a class for amateurs and nurserymen for twelve Teas or Noisettes, Mr. George Mount won easily with a grand box, Mr. Frank Cant being second, and Colonel Pitt third.

#### EARL'S COURT.—JUNE 28TH.

NOTWITHSTANDING the numerous counter-attractions in the shape of flower shows elsewhere, exhibitors mustered strongly at the Gardening and Forestry Exhibition on the above date, when a special show of Roses and other flowers and fruit was held.

The principal class was for forty-eight Roses, distinct, single trusses, and in this six of the leading growers exhibited, making the competition somewhat keen. Messrs. Harkness & Sons, Bedale, were, however, awarded the first prize for a stand of magnificent blooms. These were Gustave Piganeau (grand), Lady Mary Fitzwilliam, Comte de Raimbaud, Marquise de Castellane, Le Havre, Mrs. J. Laing, Marie Baumann (fine), François Michelon, Caroline Kuster, Horace Vernet, Jean Ducher, Fisher Holmes, Madame Bravy, Thomas Mills, Pride of Waltham, Dr. Sewell, Madame Hausman, J. S. Mill, The Bride, Rosieriste, Captain Christy, Crown Prince, Earl of Dufferin, Sport, Alice Perkins, Louis Van Houtte, Madame Isaac Pereire, Dr. Andry, Heinrich Schultheis, A. K. Williams (splendid), Madame E. Verdier, Madame G. Luizet, Duchess of Bedford (grand), Madame Cusin, Charles Lefebvre, Souvenir de Paul Neyron, Edward Andry (very fine), Comtesse de Nadaillac, Senateur Vaisse, Barthelemy Joubert, Queen of Queens, Duke of Edinburgh, Dupuy Jamain, La France, Xavier Olibo, Souvenir de S. A. Prince, Camille Bernardin, and Marie Verdier. Mr. Frank Cant, Colchester, was a good second, showing grand blooms; Mr. B. R. Cant being third.

For twenty-four Roses, distinct, three blooms of each, Messrs. Harkness & Sons and Mr. Frank Cant were awarded equal firsts, so close was the competition. The varieties shown by Mr. Cant were Pride of Waltham, Horace Vernet, Baroness Rothschild, Charles Lamb, Dupuy Jamain, Madame Hippolyte Jamain, Prince Arthur, Catherine Mermet, Merveille de Lyon, Suzanne Marie Rodocanachi, Alfred Colomb, Marie Verdier, Duke of Wellington, Souvenir d'Elise Vardon, A. K. Williams (grand), Gustave Piganeau, Mrs. John Laing, Duke of Edinburgh, Madame Gabriel Luizet, Prince Camille de Rohan, Xavier Olibo (fine), Souvenir d'un Ami, Sir Rowland Hill, and Innocente Pirola. In Messrs. Harkness & Sons' stand A. K. Williams, Marie Baumann and Madame Gabriel Luizet were very fine. The third prize went to Mr. G. W. Burch, Peterborough, who staged excellent blooms.

Mr. G. W. Burch was first in the class for twenty-four single trusses, staging a grand stand of blooms. The varieties were Her Majesty, Senateur Vaisse, Ulrich Brunner, Marie Rady, Duke of Connaught, Alfred Colomb, Madame Eugenie Verdier, Madame Victor Verdier, Xavier Olibo, Innocente Pirola, Comte Raimbaud (grand), Mrs. J. Laing, Horace Vernet, Madame de Watteville, Pierre Notting, Madame Charles Crapelet, Exposition de Brie, Dr. Sewell, Madame Lambard, Victor Hugo, Madame Gabriel Luizet, Fisher Holmes, Etienne Levet, and Duke of Wellington. Mr. Frank Cant was second with fine blooms, and Messrs. Perkins and Sons, Coventry, third.

Teas and Noisettes were fairly good. In the class for twenty-four blooms Mr. B. R. Cant, Colchester, was first. The best flowers in this stand were Ethel Brownlow, The Bride, Souvenir d'Elise, Catherine Mermet, Mrs. J. Wilson, and Madame Lambard. Mr. F. Cant was second, these being the only exhibitors. Mr. G. Mount, Canterbury, was first for eighteen Teas and Noisettes. Messrs. D. Prior & Son, Colchester, were second, and Mr. G. W. Burch third. For twelve blooms of any Tea or Noisette, Mr. H. V. Machin was first with Souvenir de S. A. Prince, Messrs. W. Prior & Son were second with Maréchal Niel, and Mr. B. R. Cant third.

For eighteen bunches of garden Roses Messrs. G. Paul & Sons,

Cheshunt, were awarded first prize, the second honour going to Mr. Charles Turner, and the third to Mr. G. Mount. The class for twelve blooms of any dark variety was very good. Mr. B. R. Cant was placed first, however, for twelve splendid specimens of Alfred Colomb, Messrs. Harkness & Sons were second with Charles Lefebvre, Mr. F. Cant being third with Reynolds Hole in fine condition. Mr. G. Mount was first for twelve blooms of any light Rose, showing fine specimens of Her Majesty, Messrs. Harkness & Sons were second with Mrs. J. Laing, and Mr. B. R. Cant third with Her Majesty. Mr. G. Mount also won the first prize for a basket of Roses arranged for effect, the second award going to Messrs. Perkins & Sons, Coventry, and third to Mr. J. Wetton, Fulham.

In the amateurs' section Mr. E. B. Lindsell, Bearton, Hitchin, was first with twenty-four Hybrid Perpetuals, showing fine blooms. The best were Alfred Colomb, Charles Lefebvre, A. K. Williams, Horace Vernet, and Marie Baumann. The Rev. J. H. Pemberton, Havering-atte-Bower, was second, and Mr. J. Parkes, Oakfield, Hitchin, third. The Rev. J. H. Pemberton and Mr. E. B. Lindsell were awarded equal firsts for twelve Hybrid Perpetuals, both exhibitors staging good flowers. Mr. J. Gurney Fowler, Glebelands, South Woodford, was third in this class. The Rev. H. A. Berners, Harkstead Rectory, Ipswich, was placed first for twelve Hybrid Perpetuals, the second and third prizes going to Mr. J. Gurney Fowler and Mr. Harcourt P. Landon, The Lodge, Shenfield.

The first prize for eighteen Teas and Noisettes in the amateurs' section went to H. V. Machin, Esq., Worksop, as the only exhibitor in this class. The Rev. H. A. Berners was first with twelve Teas and Noisettes, which included The Bride, Madame Bravy, and Innocente Pirola in good condition. Mr. J. Parkes was third.

Miscellaneous exhibits include a grand collection of Roses, which represented all sections. The flowers were very fine and fresh. Messrs. Barr & Sons had a charming collection of hardy flowers. Mr. T. S. Ware, Tottenham, was awarded first prize for a grand group of Tuberous Begonias tastefully arranged. Mr. J. Walborn, West Kensington, had a group of Carnations, and floral decorations were shown by Messrs. Perkins & Co., J. Chard, and others. Mr. S. Mortimer, Rowledge, Farnham, sent a collection of Melons and sprays of Stephanotis, splendid flowers (silver-gilt medal).

Fruit was grandly shown, but want of space forbids a detailed report. Mr. J. McIndoe, Hutton Hall Gardens, Guisborough, was first with three bunches of white Grapes, showing Muscat of Alexandria; Mr. T. Osman, Ottershaw Park, being second with Buckland Sweetwater. Mr. Osman was first for black Grapes, and Mr. J. Travener, Woolmer, Liphook, second. Mr. McIndoe was first for six dishes of fruit. Mr. A. Ocock, Havering Park, Romford, second, and Mr. W. Robins, Hartwell House, Aylesbury, third. Mr. W. Allan, Gunton Park, Norwich, was first for three dishes of Strawberries. Mr. W. H. Divers was placed first for one dish, and Mr. W. Foreman, Louth, sent some fine Strawberries, named Ruby, Duchess of Connaught, Conquering Hero, and Climax. Mr. J. Gurney Fowler was first for a dish of Cherries, Mr. W. H. Divers being second. Figs were best shown by Mr. W. Allan, and Nectarines by Mr. W. Robins. Mr. Stocking, Marden Park, secured the leading prize for six Peaches, showing Bellegarde, Mr. W. H. Divers being second. Mr. H. Poulton, Streatham, was first with one Melon and also for three Melons, staging grand fruits. Messrs. T. Rivers & Son sent a collection of Cherries, Peaches and Plums, and Mr. W. Allan six boxes of Strawberries. Mr. Featherly, Gillingham, Kent, sent Tomatoes, Cucumbers, and Grapes.

#### RICHMOND.—JUNE 28TH.

BRIGHT but somewhat gusty weather attended the opening of the great annual Show in the pleasant Surrey town this year. There was a falling off in one or two departments so far as quantity was concerned, especially amongst the Roses, but the four large marquees erected were very well filled, and the Exhibition as a whole was a fine one. The arrangements were well carried out under Mr. Ford's directions. Time and space only permit of a much condensed report, but the principal awards are appended.

Roses are the flowers of the period and claim attention first. The display was hardly so extensive as last year, but the blooms were of excellent quality. Mr. B. R. Cant was first with forty-eight trebles, exhibiting a most even and fresh collection of flowers. A. K. Williams was extremely fine, while Gustave Piganeau, Comte de Raimbaud, and Alfred Colomb were very good. Messrs. Paul & Son, Cheshunt, were second with neat flowers but somewhat marred by the weather, Duke of Connaught and Alfred Colomb being perhaps the best. Mr. Rumsey, Waltham Cross, was third. There appeared to be only one exhibitor of twenty-four trebles—viz., Mr. Mount, who had an excellent stand, in which Mrs. John Laing, Marie Baumann, and Duke of Edinburgh were the most noteworthy. It was the same with twelve, Mr. W. Tayler being the only entrant to appear, and the second prize was given to him. Messrs. Perkins & Sons had the best twelve of one variety, a very even, fresh and richly coloured dozen of A. K. Williams. Mr. B. R. Cant was second with Reynolds Hole, and Mr. Mount third with Fisher Holmes. In the corresponding Tea class the latter won easily with a beautiful box of The Bride, Mr. B. R. Cant being second with Souvenir de S. A. Prince. R. E. West, Esq., Reigate, had a fair stand of twenty-four in the amateurs' class for that number, and won from Mr. Warwick, gardener to J. P. Kitchen, Esq. They were also first and second with twelve, Mr. Ladbury being third in both

cases. The principal winners in the local classes were Messrs. Wigan and Twining.

Groups of plants were numerous and good, albeit of a somewhat stereotyped character. Mr. H. E. Fordham was first, and may be complimented on the taste in arrangement displayed. Mr. Finch, gardener to W. Marriott, Esq., had in his praiseworthy desire to avoid over-colouring gone to the other extreme, but managed to secure the second prize. Mr. W. J. Brown was third, and Mr. H. James fourth, both groups being overloaded. There were other good groups in competition for the special prizes, as well as others not for competition, so that on the whole they formed a considerable feature. Palms and specimen plants were excellent. Mr. Finch was first in the principal class, and a grand Croton Queen Victoria, very large and well coloured, was amongst his plants, all of which were good. Mr. Debnam, gardener to A. Pears, Esq., was second; and Mr. Mould, third; the former having an excellent *Alocasia metallica* and *Maranta zebrina*. Mr. Finch also won with specimen plants in bloom, his *Ericas* being noble plants, and *Phenocoma prolifera* Barnesi in splendid condition. Mr. Mould was second, and Mr. Parsons third. Mr. Waut and Mr. Wilks (gardener to T. Cave, Esq.) were the principal exhibitors of Ferns.

Pelargoniums were not large, but very clean and well bloomed. Mr. Turner won with both Shows and Fancies. Mr. Watts, gardener to H. Little, Esq., was first with Zonals; Mr. Coombs, gardener to W. Furze, Esq., second; and Mr. F. Barnes, gardener to W. Grahame, Esq., third. They were fairly good throughout, but Ivy-leaved were only moderate, and a second prize was awarded to Mr. Watts. Mr. Howard, grower to H. Little, Esq., won with six Orchids, Mr. Young, grower to F. Wigan, Esq., following. Mr. Howard had some excellent pieces. Mr. Waut, gardener to F. Wigan, Esq., had some grand Caladiums, and was deservedly placed first; while Mr. Coombs won with Coleuses, Mr. Parsons, gardener to T. Twining, Esq., following. Messrs. Sutton's prizes for Gloxinias brought out some well-bloomed plants, but they appeared to have been subjected to wind or otherwise shaken.

Fruit was not very abundant, but there were several noteworthy exhibits. Mr. Osman, Ottershaw Park Gardens, had excellent Grapes and other produce in the leading class, and defeated Mr. Sage, gardener to Earl Dysart, somewhat easily, the latter being weak in Grapes. Mr. Osman won still more decisively with black Grapes, his clusters of Black Hamburgs being very fine. Mr. Ford, gardener to W. H. Ellis, Esq., was second, and Mr. Springthorpe, gardener to W. A. Bevan, Esq., third. Mr. Ford had his revenge with whites, winning from Mr. Osman with large bunches of Foster's Seedling. Mr. Wilkins, gardener to Lady Theodore Guest, third. In other Grape classes Messrs. C. W. Knowles, Sage, Parsons, Burton, and Wilks secured the prizes. Mr. Parsons won with Strawberries; Mr. Simmonds, gardener to W. Cunard, Esq., with Peaches, Nectarines and Tomatoes; and Mr. Wilks with Melons.

The special prizes for vegetables brought out some splendid produce. Mr. Wilkins showed extremely well for Messrs. Sutton's prizes, and received the principal award, the second going to Mr. Waite, gardener to Colonel Talbot, and the third to Mr. J. Smith, gardener to W. H. Odium, Esq. Space does not admit of particulars. In the competition for Messrs. Carter's prizes the result, so far as the two principal awards are concerned, was the same, Mr. Wilkins and Mr. Waite having a good fight for the first place, which fell to the former. Mr. Higginson, gardener to General Vialls, was third. Mr. Waite secured the first of the Society's prizes for a collection, and in another similar class Mr. Sage was successful.

Messrs. James Veitch & Sons sent a beautiful group of *Lilium longiflorum* surrounded by *Aralias* and *Eurya latifolia variegata*, not for competition. Messrs. J. Laing & Son had a delightful display of stove and greenhouse plants, with many fine Begonias. Mr. Chas. Turner contributed a collection of splendid Malmaison and Germania Carnations, which were greatly admired. Messrs. Peed & Son had a bright and tastefully arranged group of indoor foliage and flowering plants, Mr. William Icton a large group of Palms and foliage plants, Messrs. Hugh Low & Co. a very attractive collection of choice Orchids, Messrs. Cutbush & Co. a cheerful and varied display of hardy flowers, Messrs. H. Cannell & Sons some beautiful Begonias tastefully arranged, and Messrs. G. Jackman & Son several good stands of Roses.

#### HARDY FRUIT GARDEN.

**Moistening Fruit Tree Borders.**—It is important that the borders in which Peaches, Nectarines, Apricots, and other fruit trees are growing be kept sufficiently moist during the critical period of fruit development and growth extension. In applying moisture the full extent of the roots both downwards and laterally must be reached. During hot weather it is not only the sun which abstracts moisture from the soil, but the foliage by extra evaporation from its surfaces makes greater demands upon the roots. If the latter cannot supply the needful

support the foliage suffers, becoming a prey quickly to red spider and other pests. Well drained borders and those formed on light soils suffer the most. Even with the mulch deposited some time ago on the surface, with probably a good watering at or near that time, the extended dry weather will have created a demand for more moisture, especially now the fruit is swelling. If the borders have a smooth surface this will require loosening to allow the water to percolate easily. A fork carefully used will effect this without injuring the fibres. Do not give cold hard water until it has been softened and exposed to the weather. If obtainable, rain water is best. One good application, reaching the full extent of roots, is better than dribbles supplied at short intervals.

**Feeding Fruit Trees.**—It is wasteful and injurious to apply fertilisers to fruit trees if the borders or soil occupied with the roots should be dry. Therefore, before applying liquid or artificial stimulant contrive to have the soil moistened. Weakly and heavily cropped trees may then be fed with advantage, the assistance thus given aiding the growth of the wood and fruit. Follow with a mulch of partly decayed manure to prevent rapid evaporation. Subsequent waterings and heavy rains will carry the virtues in the manure down to the roots. Some of the many excellent chemical manures advertised may be applied beneficially now to trees swelling their crops.

**Syringing Wall Trees.**—To keep the trees clean syringing ought to be done frequently in dry, warm weather, daily if possible, commencing about 4 P.M. at this season. Early morning syringing in very hot weather is beneficial; especially where wall trees are situated in the neighbourhood of tall trees, bushes, or shrubberies is syringing necessary, and forcible applications reaching both sides of the leaves will keep red spider at bay. Young shoots of Cherries and Plums are in many places badly infested at the points with aphides. These ought previously to be dipped in a solution strong enough to kill the pests. Softsoap at the rate of half a pound of soap dissolved in four gallons of water with a pint of tobacco water added is safe.

**Cherries.**—Many varieties of Cherries are now either ripe or fast approaching that condition. To protect the fruit on large trees from birds is a difficult matter; but wall trees can be easily protected with nets hung in front from the top of the wall, keeping them clear of the foliage and fruit.

#### FRUIT FORCING.

**Pines.**—*Starting Suckers.*—The necessary provision for starting the suckers, which will soon be fit to be taken from the plants that formed the early section of summer fruiterers, should be made at once. A fermenting bed in a low damp house or pit affords the most genial conditions for the suckers, and the heat in it may be 95° at the start, but it is safer to have a steady temperature of about 90° at 6 inches from the surface. The suckers should be divided into two sizes, have the ends pared smooth with a sharp knife, and a few of the small leaves removed from the base, but only as high up as there are roots with a brown tint issuing from the stem at their axils. Place the suckers at once in 5 or 7-inch pots according to their size, and the soil being moist no water should be given until roots are made, but if the compost be rather dry water once to settle the soil about them. Good fibrous loam torn up by hand, with a quart of soot to each bushel, is the most suitable compost, draining the pots efficiently, and sprinkling a little soot on the crocks to prevent the ingress of worms. The compost should be firmly embedded in the pots and about the suckers, which will tend to a speedy fibrous root-action, sturdier and more satisfactory growth in the plants. The house or pit should be kept rather close and moist for a week or ten days, shading effectually and giving but little air, and sprinkling the plants through a fine syringe once or twice a day according to external influences. Directly growth takes place gradually give more ventilation with less shade.

*Potting the Plants.*—Where the suckers are well rooted they must be shifted into the pots in which they are to fruit, so as to accelerate the growth as far as is consistent with sturdiness and a well-developed base. Ten-inch pots are quite large enough for Queens, Enville, and Black Jamaica, and 11-inch or 12-inch are ample for Providence and other strong growing varieties. Fibrous loam, but more lumpy than for suckers, with a 10-inch potful each of wood ashes and bonemeal to 3 bushels of the loam, grow Pines well, and to prevent worms entering the pots a little fresh soot or wood ashes may be sprinkled on a thin layer of turf placed over the drainage. Keep the plants well down in the pots, ram the soil firmly, and allow sufficient space for holding water.

**MELONS.**—*Houses and Pits Cleared of Fruit.*—As there is still time to secure a second crop or put out sturdy plants to afford a late supply of fruit, prompt decision must be made as to which it is to be. If the plants are healthy they may be reserved for another crop, in which case it is an advantage if young growths have been encouraged from the base of the plants in the latter stages of the first crop, and in some cases a good set of fruit will have been secured in these whilst the structures were kept drier for the fruit ripening. The old growths under such circumstances should be gradually cut away, reserving the most promising, and any wounds that bleed should be dried with quicklime. Remove a little of the surface soil and supply some lumpy loam. Soak with tepid water, and follow at once with liquid manure. If kept moist, but not saturated, the roots will soon spread in the loam, then they may be further encouraged by a mulching of horse droppings collected, spread in a shed and turned over two or three times before using, and it is best to supply a little of the mulch and often rather than a heavy coat all at once. Thin the fruits to half a dozen, or apportion the number to each plant according to the vigour. Second

erop fruit does not attain the size of the first, and more fruits may be had, yet overcropping is the greatest drawback to quality. If the plants have to be cut back allow a fair extension of fresh growth, and do not attempt to set the fruit until a good growth has been made, which thinly disposed will show and set fruit freely in a drier atmosphere.

*Replanting in Houses, Pits, and Frames.*—When the plants are not in a condition likely to carry a second erop, clear them out at once, remove the soil and a portion of the fermenting material, adding some fresh, which will revive the bottom heat sufficiently for the young plants. Cleanse the house or structure thoroughly. Nothing answers better as an insect destroying agent and a deterrent of attacks than syringing every part with a petroleum mixture, a wineglassful to 4 gallons of water, one person syringing into the vessel, while a second forcibly applies it to the woodwork. In a few days the smell will pass off, and the plants have the benefit of a clean start. Plant on hillocks or ridges in houses, and add soil afterwards, but in frames or pits a couple of barrowloads of soil in a light will grow a large plant, and it saves much trouble afterwards. Good strong loam is best, ramming it firm, and when warm plant the Melons. Those for frames should be strong, but not root-bound plants. Shade for a few days, and maintain a moist atmosphere, but ventilate freely after the plants become established.

*Setting the Fruit.*—Though artificial impregnation is not so essential now as earlier in the season, it is a mistake not to attend to this operation at the proper time, that is, when the flowers are fully open. If there be any difficulty, as there sometimes is in frames in getting the fruit to set, apply good linings and admit air freely, ventilating a little at night, so as to prevent the deposition of moisture on the blossoms, for to set it is necessary that the pollen be dry and the stigmas not destroyed by moisture. It is not desirable to use the knife much during setting, nevertheless light and air are essential, therefore keep the foliage fairly thin, and stop the laterals one joint beyond the pistillate blossoms after fertilising. Avoid giving water if it can be helped at this stage, yet the foliage must not flag for lack of it, nor the surface be wetted more than can be helped in supplying the requisite quantity.

## THE BEE-KEEPER.

### APIARIAN NOTES.

#### THE WEATHER AND BEES.

THE long-continued heat and drought gave way suddenly on the afternoon of the 22nd inst., and rain continued almost without intermission for twenty-four hours. This change was welcomed by bee-keepers, gardeners, and farmers. The thermometer on the 18th in the shade stood at 85° for a great part of the day, and on the morning of 20th it stood at 40°. On several nights preceding it registered 60°. Such excessive heat with dust and drought was not favourable to a honey flow. Our season is now on, and with a few fine days during the next two or three weeks bees will exert themselves, and heavy hives with well filled and sealed supers will result.

#### PUNIC BEES.

For the first time during the past three years I have been able to test the honey-gathering qualities of the pure race. The swarm referred to at page 512, owing to some of the bees on returning not finding their queen in the cluster, was not as large as it might have been. When weighed on the evening of the 18th it had risen in weight 25 lbs., although supplied with strips of foundation an inch broad only. The swarm of crossed Punic referred to on the same page with two working days added, weighed 102 lbs.; 24 lbs. of that have been taken in supers. With us these bees are working well, and I would advise bee-keepers to give them a fair trial. It is remarkable that only 5 per cent. of my Punics have swarmed, the others working as yet contentedly in their two tier of supers ready for additional room; while my pure Punic swarm on a return of fair weather will be supplied with them.

#### VENTILATION—WAX EXTRACTING.

When the temperature was high the ventilating floors were dropped, but to little purpose, as it allowed a greater rush of heated air to enter the hive. Shading, by hanging a mat loosely round the hive, has a better effect when there are no cooling breezes. When the heat was at its greatest one of our Carniolan hives turned its drones outside, where they clustered till the evening, when they re-entered the hive.

A sun wax extractor is of but little service in this country, the sun being too low when most wanted; still it is a mistake to allow scraps of wax to lie about as a nidus for moths. All scraps of wax, either as a point of economy or as a deterrent to the increase of these pests, should be melted at once, or dropped into boiling water till a convenient time to extract properly. When the temperature rises to 75° and upwards a solar extractor is service-

able. All that is necessary is a tin dish about 3 inches deep, of any size, but oblong is the best shape, covered with a pane of glass let into a light frame, having a projecting ledge to prevent slipping and escape of heat, and stood upon a slate or other conductor. The tin should have a gateway of glass from the lower end, raised a little to allow the melted wax, but not the refuse, to run through. It should be raised to a proper angle to catch the direct rays of the sun. I have one placed upon an elevator which turns to any angle. Although I have mentioned tin, it would be far more effective if made of copper, pewter, or any of the combination metals of a highly conductive nature.

#### HONEY CANDYING IN THE COMB.

"R. A. C." wishes to know if honey candies in the comb. Honey sometimes candies in the comb, especially that gathered from Charlock, but more quickly out of the hive than in it, unless it is kept in a dry and warm place. Sugar also crystallises in the comb, but it partakes more of candy than honey crystals. Doubtless the best samples of honey in the comb do not crystallise so readily as inferior ones. The care you exercise with your honey in keeping it clean and having it of the best quality is commendable. The Lanarkshire hives are a success, entirely through the impossibility of damp injuring the bees in the latter. It is clear proof that bee-keepers are the best judges.—A LANARKSHIRE BEE-KEEPER.

\*All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

**Sparrow Guns** (W. S.).—The address you require is E. P. Timmins, 90, Balsall Heath Road, Birmingham.

**Chrysanthemum Soil** (D. M. S.).—The plant arrived too late for examination to give a detailed reply in this issue, but the matter shall be attended to next week.

**Night-blooming Cereus** (R. T. H.).—The facts set forth by our correspondents on page 498 show that it is not an unprecedented occurrence for a Night-blooming Cereus to have more than nine flowers at one time. The remarks of Mr. Major on page 516 of this issue are interesting.

**Tomato Disease** (St. Julien).—The matter is being investigated, and a reply will be given in our next issue. The leaf, however, arrived in a very poor condition, and it would be better to always pack such in a box. The article "What Pays Best?" by a "Market Grower," in the present issue, you will doubtless read with interest.

**Lord Napier Nectarine Fruits Shrivelled and Rusted** (J. B.).—The Nectarines are not matured, though of good size, but that is not the cause of the shrivelling nor of the rust, which are peculiarities of this variety. The shrivelling generally indicates fine fruit and high quality, vigorous trees being more subject to it than those only moderately so, and the fruit smaller, and it is less pronounced in early forced fruits than in those produced by trees in midseason or late houses. That the shrivelling is characteristic may be inferred from the fact that fruits grown on the upper side of the trellis, and exposed to the sun, are no more affected than those on the under side of the trellis, where they are shielded from direct sunshine, and that it almost invariably is most pronounced at the apex of the fruit. This greatly detracts from its appearance, but the quality is excellent, as is shown by ants preying upon it before it is ripe, leaving most every other variety for it. The rust is generally an accompaniment of the shrivelling, and rarely extends beyond the shrunken parts. We find the rust most pronounced where heavy or frequent syringing is practised, especially when the trees are vigorous, and the water hangs on them during the night and remains until the morning, and where the water used is impregnated with lime or iron. Both the shrivelling and rust are less prevalent where clear soft or rain water is used, but under no conditions have we seen full-sized and well-ripened fruit of this variety without slight shrivelling and its accompanying rusty appearance.

**Peach Leaves Eaten** (W. M.).—The perforated leaves have been eaten by some weevil, which, from the gnawing, appears to be a species of *Otiorhynchus*, the black Vine weevil (*O. sulcatus*), and the clay-coloured or pitchy-legged weevil (*O. picipes*) being the most common preyers on Peach leaves, and not infrequently feed in company. The best remedy is to capture the weevils by spreading cloths beneath the trees in the daytime (housemaid's dust sheets answer well), and at night the house should be cautiously entered with a lantern giving a good light when exposed, but it ought to be covered until the tree or trees be reached, then turn on the light, shake the branches sharply and capture the fallen beetles, killing them by placing in boiling water or a pail containing gas tar. This repeated from time to time will clear the trees from the pests.

**Primula rotundifolia** (M. C.).—The accompanying sketch (page 94), although reduced, will give you an idea as to the appearance of this *Primula*, which is considered by some authorities to be quite as hardy as *P. rosea*, with a similar habit, and requiring much the same kind of treatment. The leaves, as in *P. rosea*, are deciduous, dying off in winter, forming a small compact sulphury white bud, which may be easily protected from the ravages of birds and insects with a few small pebbles or a handful of cocoa-nut fibre. The leaves are orbicular, cordate, crenately toothed, bright green above, and entirely covered with meal on the under side, somewhat resembling *P. Stuarti* or *purpurea* (of Royle); the stalk 4 to 12 inches long, and the blade 3 to 4 inches in diameter. The flower stem grows from 6 inches to a foot in height, with two and often three whorls of bright rosy red flowers as large as those of *rosea*, with a pale yellow ring round the throat. So far as our

FIG. 94.—PRIMULA ROTUNDIFOLIA.

experience goes it will grow as readily as the hardy *P. rosea*, all the capsules being large and promising plenty of seeds. It is found on the Singahelah range from 12 to 18,000 feet above sea level, and from Kashmir to Sikkim.

**Insects on Duke of Albany Peas and Parsnips** (T. N. B.).—The specimen pods of Duke of Albany Peas, from a sowing made on March 7th, are very good; those from another sowing on March 17th are troubled with two kinds of insects—one, thrips on both the haulm and pods, but the insects were not present, therefore we are unable to tell the species with exactitude, yet the traces are those of *Heliothrips minutissima*. The best remedy for these pests is to syringe the Peas with a solution of softsoap, 2 ozs. to a gallon of water, or ordinary soap-suds may be used, provided they do not contain bleaching powder or large quantities of washing soda, straining them so as not to clog the syringe; afterwards follow with a few good washings with clear water in the evening of alternate days. Although there is no insect in the blotches in the leaflets, the larva of the Pea fly (*Phytomyza nigricornis*) has been there, and probably now is in other parts. As the larvæ live by mining and eating the internal tissue of the leaves, the only remedy is to crush them between the finger and thumb, or pick off the affected parts and burn them, but the former plan is best, as the latter weakens the Pea growths. For the green fly on the Parsnips you may proceed in a similar manner as advised for thrips on the Peas, adding a pint of tobacco juice to every 3 gallons of the softsoap solution. The other pest is the larva of the Celery and Parsnip fly (*Tephritis onopordinis*), which, burrowing in the leaves, has produced the large brown patches. The remedy is to crush the larvæ between the finger and thumb when the spots are quite small, or pick off and burn the affected parts. The leaves may be sprinkled whilst damp with fresh dry soot to prevent the fly depositing its eggs.

**Lord Napier Nectarines Shrivelled at the Apex** (G. G.).—The fruit is slightly rusted and shrivelled at the apex, and is peculiar to and characteristic of the variety, especially in a hot and dry season. There is nothing in your management to account for the defectiveness of the fruit. It does not affect Peaches, at least not the varieties grown in this country, which are not clingstones, and in Nectarines it is mostly confined to them, rarely affecting the freestone varieties. See reply to "J. B." on page 526.

**Mangold Wurtzel Plants Eaten by Grubs** (B. B. H.).—The "grubs" are the larva of the common crane fly or daddy longlegs (*Tipula oleracea*), which have such tough skins as to have procured for them the name of "leather jacket." They generally lie, as you describe, about an inch below the surface, and near to the plants they prey upon, hence slices of Mangold Wurtzel, Swedes, Carrots, and Potatoes may be employed with success for the protection of the seedlings. They should be sunk an inch or so below the surface of the soil, and be examined every two or three days, the grubs found in them being removed and destroyed. This is a tedious method, but a certain cure. As a top-dressing, nitrate of soda at the rate of 2 cwt. per acre acts well, both by benefiting the plants and injuring the grubs. The nitrate of soda should be finely powdered and be sprinkled on the drill, so as to act quickly and with least prejudice to the plants, it being best to apply it near them, but keep it from the hearts of the plants. The grubs seem to be paralysed by the nitrate of soda, become helpless, ultimately dying. Guano 1½ cwt., kainit 1 cwt., superphosphate 1 cwt., and salt 2 cwt., mixed, per acre, have also been applied with advantage.

**Names of Plants.**—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss, soft green grass or leaves form the best packing, dry wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*F. D.*)—*Kalmia latifolia*. (*N. P.*)—*Spiraea Thunbergii*. (*L. E.*)—*Lycaste Skinneri*, a good form. (*Amateur*)—*Spiraea aruncus*.

### THE GREAT DROUGHT.

IN recording the effect of the drought upon farm crops the common tendency to lay stress upon extreme cases is altogether misleading and mischievous. According to some reports grain crops are completely burnt up, and the land is an arid waste, Rye, Wheat, and Barley have perished, vast tracts of land remain unploughed owing to the hardness of the soil, and the hay crop is a failure. Undoubtedly this may be said truthfully of certain localities, but it is assuredly not applicable to the country generally. On the week in which the Royal Agricultural Society's Show opened at Chester we travelled from London to Manchester by the Midland Railway, then on to Chester, returning by the North-Western route. Generally, crops were green and flourishing; hay-making was in progress everywhere, and though the crop is a short one on many farms there are numerous exceptions, especially in Lancashire, Cheshire, and Staffordshire, where a really good crop of grass was being made into hay. Near Lichfield we saw a crop of mixed seeds, so abundant that the haycocks a'most touched. It was a remarkable crop for any year, and was probably to be accounted for by the huge sewage pipe which we saw running in its direction from Lichfield. Everywhere hay of the very best quality was being made, and if only rain comes freely and soon it will be quite possible to make enough silage to afford an ample supply of wholesome nutritious fodder for next winter and spring.

A question frequently upon the mind is, Will farmers generally rise to the emergency, and turn to ensilage if they have green crops to spare for it later on? There can be no doubt that hay will be scarce next winter; it is so scarce now that it is said to be rising in price daily, and it is reported that on June 17th in Cumberland Market the best English meadow hay was selling at £8 10s. per load, which means about £9 10s. per ton. At the Royal Show at Chester we saw a bale of Timothy hay, compressed and bound with wire, which the Canadian agent told us could be delivered from Canada at Liverpool profitably for £4 5s. per ton. The bales weigh from 1 to 2 cwt., and the hay is sweet and wholesome enough, but it will never spoil the market for our best meadow hay, and though it may be useful horse fodder when cut into chaff, its hard wiry stalks yield chaff which is much inferior to that obtained from well-managed winter Oats. In his book on "Permanent and Temporary Pastures," Mr. Martin J. Sutton says of Timothy, "I regard it as decidedly inferior to Foxtail. The herbage is coarse, the stalks soon become hard, and their increased feeding value in that state is of no avail if cattle refuse to graze them, as they undoubtedly do; or if the presence of this Grass in abundance lowers the price of hay." It is therefore only under peculiar circumstances, or as a last resource, that we should advise the purchase of this hay; and if, as we were told, £4 5s. per ton is the lowest price at which it can be profitably landed at Liverpool, why it is unlikely to make its way here, at any rate in ordinary seasons.

Corn crops, though the straw is short, are generally good. Some of the spring corn, especially Oats, is uneven, having patches in ear, while other patches show no sign of ears—evidence of some of the seed corn having started into growth before the other. Very much of the Wheat is in excellent condition, inferior crops showing plainly low fertility of soil as the true cause of weakly growth. In all rich soil the influence of the drought upon Wheat is visible in the dwarfed growth rather than in any other way.

Of root crops we saw some excellent fields of Mangold, Swedes, and White Turnips, all with a full plant sufficiently advanced in growth to be safe from insect attacks. Judging

from the remarkable vigour of growth, there was plenty of farmyard manure to afford moisture to the young plant. We have always recommended ridging for early root crops, with plenty of manure in the furrows. This year it has been absolutely indispensable to sustain growth and insure a crop. There are hundreds of acres under Potatoes in the neighbourhood of Manchester and Warrington, all of them flourishing enough; the earlier sorts were being lifted for market, the moderate haulm growth showing that the crop was not a heavy one.

The Lichfield sewer was a reminder of what a boon town sewage would be to farmers this year, but systematic irrigation enters very little into British farming economy. Mr. G. F. Young, of Swineshead Abbey, South Lincolnshire, whose farm is intersected by one of the main fen drains, is a notable exception, for by means of a powerful fire engine he is pumping water from the drain at the rate of 80 tons per hour on to his crops. The water is delivered in a spray, which covers an area of from 70 to 80 yards, falling with an evenness and gentleness almost equal to heavy rain. Flexible piping several hundred feet in length is attached to the engine, which is kept stationary during the pumping.

#### WORK ON THE HOME FARM.

With the hay off the land we are anxiously looking for rain. If it comes soon and abundantly growth is certain to follow freely enough, but the parched land requires a heavy downpour to reach the roots of established crops. With such fine hot weather for the haymaking there has been some risk of overheating in the ricks from carting hastily. To avoid this small ricks are sometimes made, but we altogether prefer large ricks containing from 20 to 30 tons. Then, by carting when the hay is well made, and having one or two air shafts from the bottom during the rick building, hay of the highest quality, that will retain its condition in bulk for two or three years, is a certainty. We regard air shafts as indispensable even in the driest weather, because a large mass of new hay always generates moist heat excessively, and the shafts are just safety valves out of which the hot vapour escapes freely. The effect of over-heating is to dry up the moisture, to induce spontaneous combustion, or to discolour the hay so much that the centre of the mass is almost black when it is cut; such discolouration shows how narrowly the rick has escaped destruction by fire.

On farms where the hay crop on meadows is much below par do not forget what excellent fodder Oat straw is when cut and harvested early. When required specially for this purpose do not suffer the straw to ripen as it stands, but mow just as the grain appears, or at any rate before it begins to harden. Mow into swathes, which turn sufficiently to "hay" the straw, then cart and stack. If carted wet or too green the straw becomes musty in the stack and is unpalatable. It is either used whole or cut into chaff; sheep, cattle, and cows are all fond of it, but we prefer good meadow hay for the dairy cows. Where live stock has had to be turned into fields reserved for hay, and the outlook for next winter is consequently gloomy, this hint about Oat fodder may prove useful. Do anything rather than force half finished beasts and sheep upon the market, as so many are doing just now. If you have managed to keep stock in fair condition till now by all means make a special effort to hold them over till the autumn or early winter, when really good beasts will probably command better prices than they have done for some time. That is our hope; we can say nothing more positive, as the keen importer may also make a special effort.

#### REMARKS.

- 18th.—Clear and hot throughout.  
 19th.—Cloudless morning, then very hot, but frequent cloud in afternoon; overcast and threatening from 6 P.M. to 7.30 P.M., but with a few spots of rain. Cloudless again later.  
 20th.—Slight drizzle from 6.30 A.M. to 8.30 A.M., and overcast till about 7 P.M.; clear evening.  
 21st.—Generally overcast, with occasional spots of rain; a little sunshine in afternoon.  
 22nd.—Overcast at times, with spots of rain in morning; bright afternoon; overcast after 6 P.M., and rain from 11.30 P.M.  
 23rd.—Rain till 1.30 A.M., and from 4.30 to 7.30 A.M.; occasional sunshine in morning; bright windy afternoon.  
 24th.—Sunny at times, but generally overcast; slight showers in afternoon.  
 Notwithstanding the great fall of temperature after the 19th, the mean for the week is again above the average.—G. J. SYMONS.
